# Energy-saving electrolytic $\gamma$ -MnO<sub>2</sub> generation: non-noble metal electrocatalyst gas diffusion electrode as cathode in acid solution

Jing Tang, <sup>\*,a</sup> Hui Min Meng<sup>b</sup> and Mei Yang Ji<sup>b</sup>

$\gamma$ -MnO<sub>2</sub>, which is commercially used as an electrode material in batteries, is produced using large amounts of energy and leads to the production of high pollution as a secondary product. Ideally, this material should be fabricated by energy efficient, non-polluting methods at a reasonable cost. This study reports the green fabrication of  $\gamma$ -MnO<sub>2</sub> into a gas diffusion electrode with Pt-free catalysts in acid solution. Cobalt oxide nanoparticles were deposited on few-layer graphene sheets produced via a simple sintering and ultrasonic mixing method, leading to the fabrication of cobalt oxide/few-layer graphene. Co<sub>3</sub>O<sub>4</sub> nanoparticles are irregularly shaped and uniformly distributed on the surface of the few-layer graphene sheets. Characterization was conducted by X-ray diffraction, X-ray photoelectron spectroscopy, and field emission scanning electron microscopy. Electrochemical characterization revealed the performance of cobalt oxide/few-layer graphene gas diffusion electrode in an electrolyte of 120 g L<sup>-1</sup> manganese sulfate + 30 g L<sup>-1</sup> sulfuric acid at 100 A m<sup>-2</sup> at 80 °C. The cobalt oxide/few-layer graphene gas diffusion electrode exhibited a lower cell voltage of 0.9 V and higher electric energy savings of approximately 50% compared with traditional cathodes (copper and carbon).

## Introduction

Electrolytic manganese dioxide (EMD) may be potentially inexpensive, relatively energy dense, safe, water compatible, and non-toxic when used as an electrode material.<sup>1</sup> However, the deposition of EMD, particularly at an industrial scale, not only consumes excessive electric energy but also causes environmental damage because of the acid fog generated by the electrolytic cell.<sup>2</sup> Factories have ceased producing EMDs to protect the environment. To overcome this problem, optimization methods have been proposed to reduce the energy required for electrodeposition of manganese dioxide (MnO<sub>2</sub>). Biswal<sup>3</sup> *et al.* investigated the energy consumption of MnO<sub>2</sub> electrodeposition with the introduction of F127 (25F) in the bath and found that energy consumption can be decreased by up to 11%. In our previous work, a platinum (Pt) catalyst gas diffusion electrode (GDE) used as a cathode for electrodeposition of MnO<sub>2</sub> is proposed to save energy by approximately 60% and protect the environment.<sup>4</sup> In theory, when a Pt catalyst GDE is applied, the oxygen reduction reaction (ORR) replaces the hydrogen evolution reaction (HER). Pt and its alloys are the best-known ORR catalysts<sup>5</sup> in acid. However, catalyst-based metal-free materials,

such as Pt, are not widely applied<sup>6</sup> due to their high cost and low abundance. Although the field of electrode manufacturing has progressed considerably, the development of oxygen electrode catalysts with high activity at low cost in acid remains challenging.<sup>7</sup>

Herein, a metal-free catalyst GDE with cobalt oxide nanoparticles on few-layer graphene (FLG) is proposed as a cathode to save electrical energy (50%) and achieve environment-friendly electrodeposition to meet production requirements. The proposed catalyst and method surprisingly exhibited high performance in acid solution. The manufacturing method of the Co<sub>3</sub>O<sub>4</sub>/FLG GDE is simple and inexpensive; it may potentially replace the commercial Pt/C GDE in electrodeposition of MnO<sub>2</sub>.

## Experiment

A general two-step method was used to synthesize the Co<sub>3</sub>O<sub>4</sub>/FLG catalyst. First, 2.5 g of cotton was sintered with 5 g of cobalt nitrate solution to produce Co<sub>3</sub>O<sub>4</sub> nanoparticles, after which calcination was performed at 400 °C for 2 h<sup>8</sup> and then it was milled for 3 h. Then, 0.2 g of Co<sub>3</sub>O<sub>4</sub> nanoparticles was dispersed in 20 mL of ethanol by sonication. Subsequently, few layer graphene wrapped in a microporous membrane (450  $\mu$ m) was dipped and sonicated in the Co<sub>3</sub>O<sub>4</sub> solution for 8 h and centrifuged to form the Co<sub>3</sub>O<sub>4</sub>/FLG hybrid (Fig. 1). The sample was freeze-dried overnight at 60 °C. The GDE is a three-layer structure which consists of diffusive layer, substrate and

Fig. 1 Schematic of the methods used to prepare the  $\text{Co}_3\text{O}_4/\text{FLG}$  nanocatalyst and  $\text{Co}_3\text{O}_4/\text{FLG}$  GDE.

catalyst layer. Before the experiment began, the 60% PTFE was painted onto carbon paper (Phychemi Company Limited, China), and then it was sintered at 350 °C for 30 min. 0.25 g of acetylene black, 0.3 g of  $\text{Na}_2\text{SO}_4$ , 0.25 g of activated carbon

powder, 0.17 g of 60% PTFE (Hesen, Shanghai, China), and 100 mL of ethanol was mixed and then stirred at 80 °C to wet paste. The wet paste was cool pressed to prepare the diffusion layer (0.4 mm). The catalyst layer was prepared by blending non-

noble metal electrocatalysts, carbon black, activated carbon powder, 60% PTFE and 100 mL of ethanol as a dispersant and the rolling process was same as the diffusion layer. Furthermore, the diffusion layer and the catalyst layer was rolled on two sides of the carbon paper to obtain about 0.8 mm flat sheet. The structures and crystal phases of the catalyst were analyzed by X-ray diffraction (XRD Ultima VI) with Cu K $\alpha$  radiation ( $\lambda = 0.15406$  nm) operating at 40 kV and 40 mA. The microstructures of the catalyst and GDE were investigated using a transmission electron microscope (TEM, JEOL JEM-2100F). Surface characterization of the samples was conducted by X-ray photoelectron spectroscopy (XPS, AXIS-ULTRA-DLD) with a Mg K $\alpha$  anode. Binding energies were calibrated based on the C 1s peak (284.8 eV).<sup>9</sup> Electrochemical tests were performed using a potentiostat. Here, the working electrodes were GDEs, and a Ti-Mn array was used as the counter electrode at 100 A m<sup>-2</sup>. The electrolyte was 120 g dm<sup>-3</sup> + 30 g dm<sup>-3</sup> at 80 °C (Fig. 2).

## Results and discussion

XRD was applied to determine the phase identity and structural information of the samples. Fig. 3 shows the XRD patterns of Co<sub>3</sub>O<sub>4</sub> and Co<sub>3</sub>O<sub>4</sub>/FLG. The characteristic peaks of (111), (220), (311), (222), (400), (422), (511), and (440) are in agreement with those of the standard patterns of Co<sub>3</sub>O<sub>4</sub> with a face-centered cubic structure,<sup>10</sup> thereby suggesting that Co(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O was transformed into Co<sub>3</sub>O<sub>4</sub> at 400 °C. The relatively sharp diffraction peak at  $2\theta = 24.5^\circ$ – $27.5^\circ$  in the XRD pattern can be indexed as the graphite layer (200), indicating that the graphene is not single layer. This result is same as the research of Junming Xu.<sup>11</sup> The Co<sub>3</sub>O<sub>4</sub> in Co<sub>3</sub>O<sub>4</sub>/FLG is relatively weaker than pure Co<sub>3</sub>O<sub>4</sub>, possibly resulting in more disordered stacking and less agglomeration on the graphene sheets in the composite.<sup>12</sup> Graphene sheets present the advantages of a highly exposed surface area and electrical conductivity, which contribute to the improved electrochemical performance of Co<sub>3</sub>O<sub>4</sub>.

TEM was performed to confirm the structure of the Co<sub>3</sub>O<sub>4</sub>/FLG. The TEM images in Fig. 4 shows several large Co<sub>3</sub>O<sub>4</sub>

Fig. 3 Characterization of Co<sub>3</sub>O<sub>4</sub>/FLG and Co<sub>3</sub>O<sub>4</sub> catalysts.

nanoparticles formed on the graphene sheets, thus suggesting that Co<sub>3</sub>O<sub>4</sub> nanoparticles were doped onto the graphene sheets by the dipping method. Even after considerable sonication

Fig. 4 High Resolution Transmission Electron Microscope (HRTEM) images of the Co<sub>3</sub>O<sub>4</sub>/FLG and Co<sub>3</sub>O<sub>4</sub> inside.

Fig. 2 Schematic of Co<sub>3</sub>O<sub>4</sub>/FLG GDE electrolysis.

during the preparation of the TEM specimen,  $\text{Co}_3\text{O}_4$  nanoparticles were still closely distributed on the graphene surface.  $\text{Co}_3\text{O}_4$  nanoparticles are irregularly shaped and uniformly distributed on the surface of the graphene sheets. The interplanar distance with a spacing of 0.47 nm is consistent with the (111) facet of  $\text{Co}_3\text{O}_4$ .<sup>13</sup>

The XPS spectra reveal the elemental information of the  $\text{Co}_3\text{O}_4/\text{FLG}$  catalyst. From the survey scan of the  $\text{Co}_3\text{O}_4/\text{FLG}$  (Fig. 5a), Co, C, and O are the three elements that make up  $\text{Co}_3\text{O}_4/\text{FLG}$ . This result demonstrates that Co was successfully doped into the graphene sheets *via* the proposed two-step process. The peak at 284.4 eV (Fig. 5b) is assigned to the characteristic peaks of C 1s.<sup>14</sup> Peaks at 284.4, 285.3, and 288.9 eV are attributed to  $\text{sp}^2$  graphitic carbon (C=C) bonds, carbon bonds with  $\text{sp}^3$  hybridization, and O-C-O bonds, respectively.<sup>15</sup> The peaks located at 780.62 and 795.93 eV (Fig. 5c) are assigned to the binding energies of Co 2p<sub>3/2</sub> and Co 2p<sub>1/2</sub>, respectively, with two prominent shake-up satellite peaks at 786.5 and 804.1 eV, both of which confirm that  $\text{Co}_3\text{O}_4$  was obtained.<sup>16</sup> The predominant O 1s peak (Fig. 5d) at 530.1 and 532.5 eV corresponds to that of O species in the spinel  $\text{Co}_3\text{O}_4$  phase and the hydroxyl groups adsorbed on the surface due to our *ex situ* experimental conditions, respectively.<sup>17</sup> Therefore,  $\text{Co}_3\text{O}_4/\text{FLG}$  is likely composed of  $\text{Co}_3\text{O}_4$  on the graphene sheets surface.

Fig. 6 shows the cell voltage of traditional electrode, C GDE and  $\text{Co}_3\text{O}_4/\text{FLG}$  GDE at 100  $\text{A m}^{-2}$  in 30  $\text{g dm}^{-3}$   $\text{H}_2\text{SO}_4$  + 120  $\text{g}$

$\text{dm}^{-3}$   $\text{MnSO}_4$  at 80 °C. All the average anode potential of the experiments is almost the same which is about 0.62 V vs.  $\text{Hg}_2\text{SO}_4$  at 100  $\text{A m}^{-2}$  and the electrodeposition efficiency of  $\gamma\text{-MnO}_2$  is not affected. However, the cell voltage of the electrodeposition of  $\text{MnO}_2$  using  $\text{Co}_3\text{O}_4/\text{FLG}$  GDE as cathode is lower than that of the electrodeposition of  $\text{MnO}_2$  using traditional electrode. It is because the anode reaction of traditional electrode is the same as that of gas diffusion electrode. The gas diffusion electrode is

Fig. 6 Cell voltage of traditional electrode, carbon electrode, Cu electrode, C GDE,  $\text{Co}_3\text{O}_4/\text{FLG}$  GDE and Pt/C GDE at 100  $\text{A m}^{-2}$  in 30  $\text{g dm}^{-3}$   $\text{H}_2\text{SO}_4$  + 120  $\text{g dm}^{-3}$   $\text{MnSO}_4$  at 80 °C.

Fig. 5 XPS spectra of (a) the  $\text{Co}_3\text{O}_4/\text{FLG}$ , (b) C 1s spectra of the  $\text{Co}_3\text{O}_4/\text{FLG}$ , (c) Co 2p spectra of the  $\text{Co}_3\text{O}_4/\text{FLG}$  and (d) O 1s spectra of the  $\text{Co}_3\text{O}_4/\text{FLG}$ .

employed in the electrolytic manganese dioxide cell instead of the traditional electrode, the electrochemical reaction is:

Gas diffusion electrode as cathode: overall 4 electron reaction forming water

Or two electron process, forming unwanted  $\text{H}_2\text{O}_2$

After doping of the  $\text{Co}_3\text{O}_4$  nanoparticles into the graphene sheets, the cell voltage of the  $\text{Co}_3\text{O}_4/\text{FLG}$  GDE decreased drastically to 0.9 V, similar to the ORR catalyzed by a high-quality commercial Pt/C GDE (0.8 V). The Pt/C catalyst is acknowledged to be the most effective catalyst for oxygen reduction reaction in acid media. In our previous studies, the ORR, catalysed by the Pt/C catalyst, proceeds *via* both the two electron transfer and the four-electron transfer, but four-electron transfer is the main process in  $30 \text{ g dm}^{-3} \text{H}_2\text{SO}_4 + 120 \text{ g dm}^{-3} \text{MnSO}_4$  at  $80^\circ\text{C}$ .<sup>18</sup> However, cell voltage of C GDE in  $\text{H}_2\text{SO}_4$  is 0.5 V higher than the Pt/C GDE, as expected, since C GDE features a two electrons transfer to product  $\text{H}_2\text{O}_2$  in acid solution which is same as the research of Ichiro Yamanaka.<sup>19</sup> The cell voltage of C GDE is 1.3 V which is 0.4 V higher than that of  $\text{Co}_3\text{O}_4/\text{graphene}$  GDE in electrodeposition of  $\gamma\text{-MnO}_2$  while it was similar to Pt/C GDE, indicating that ORR of  $\text{Co}_3\text{O}_4/\text{FLG}$  GDE in  $30 \text{ g dm}^{-3} \text{H}_2\text{SO}_4 + 120 \text{ g dm}^{-3} \text{MnSO}_4$  at  $80^\circ\text{C}$  is both two electrons transfer (eqn (4)) with the formation of  $\text{H}_2\text{O}_2$  and the four-electron transfer (eqn (3)) producing  $\text{H}_2\text{O}$ .<sup>20</sup>

In order to manifest the cause of the high activity of the  $\text{Co}_3\text{O}_4/\text{FLG}$  GDE in the electrodeposition of  $\text{MnO}_2$ , a two-electrode cell assembly was fabricated using the proposed GDE as the cathode, a Ti-based Ti-Mn array as the anode, and  $120 \text{ g L}^{-1} \text{MnSO}_4 + 30 \text{ g L}^{-1} \text{H}_2\text{SO}_4$  as the electrolyte. Fig. 7 shows the cell voltage–time curves of  $\text{Co}_3\text{O}_4$  GDE, FLG GDE,  $\text{Co}_3\text{O}_4/\text{FLG}$  GDE,  $\text{Co}_3\text{O}_4/\text{C}$  GDE,  $\text{MnO}_2/\text{FLG}$ , Pt/C GDE, carbon electrode, and copper electrode at  $100 \text{ A m}^{-2}$ .  $\text{Co}_3\text{O}_4$  exhibited very poor ORR activity with an initial cell voltage of 1.3 V that increased slowly to 1.6 V after 10 h due to its poor conductivity and the small surface area of  $\text{Co}_3\text{O}_4$ .<sup>21</sup> However, The  $\text{Co}_3\text{O}_4/\text{C}$  GDE revealed poor ORR like  $\text{Co}_3\text{O}_4$  GDE indicating that C didn't make  $\text{Co}_3\text{O}_4/\text{C}$  GDE work better. The cell voltage of FLG GDE and  $\text{MnO}_2/\text{FLG}$  GDE revealed poor ORR activity with a cell voltage of 1.3 V because of low corrosion resistance of the  $\text{MnO}_2$  and low ORR activity of graphene. However, the  $\text{Co}_3\text{O}_4/\text{FLG}$  nanocatalyst is much more active than either pure  $\text{Co}_3\text{O}_4$  or FLG nanocatalysts in the electrodeposition of  $\text{MnO}_2$ . The  $\text{Co}_3\text{O}_4/\text{FLG}$  GDE can save up to  $\sim 50\%$  of the electric energy required by traditional cathodes (Cu and C) in Fig. 6. The increased activity of the proposed GDE may be attributed to synergistic effects

Fig. 7 Cell voltage test:  $\text{Co}_3\text{O}_4$  GDE, FLG GDE,  $\text{Co}_3\text{O}_4/\text{FLG}$  GDE,  $\text{Co}_3\text{O}_4/\text{C}$  GDE,  $\text{MnO}_2/\text{FLG}$ , Pt/C GDE at  $100 \text{ A m}^{-2}$  in  $30 \text{ g dm}^{-3} \text{H}_2\text{SO}_4 + 120 \text{ g dm}^{-3} \text{MnSO}_4$  at  $80^\circ\text{C}$  (all the anode potential of the experiment is almost the same which is about 0.62 V vs.  $\text{Hg}_2\text{SO}_4$ ).

Fig. 8 The product of electrolysis using  $\text{Co}_3\text{O}_4/\text{FLG}$  GDE.

between the  $\text{Co}_3\text{O}_4$  nanoparticles and FLG<sup>22</sup> with the large electrochemically active surface area<sup>23</sup> and excellent conductivity,<sup>24</sup> which can improve the conductivity and change the charge transfer across the interface. Therefore,  $\text{Co}_3\text{O}_4$  doping of FLG plays a key role in improving the electrocatalytic activity of GDEs for green electrodeposition of  $\text{MnO}_2$  in acid solution.

Fig. 8 exhibits XRD patterns of the product of electrolysis. The four sharper peaks appeared at  $37.3^\circ$ ,  $42.7^\circ$ ,  $56.5^\circ$  and  $67.3^\circ$  which are ascribed to the (021), (121), (221) and (061) planes of  $\gamma\text{-MnO}_2$ .<sup>25,26</sup>

## Conclusion

In summary, a nanocomposite of  $\text{Co}_3\text{O}_4/\text{FLG}$  was synthesized through a pyrolysis and dipping process. The nanocomposite is simple and easily obtained in the industry.  $\text{Co}_3\text{O}_4/\text{FLG}$  was used as a nanocatalyst to catalyze the ORR in the electrodeposition of  $\text{MnO}_2$ . The proposed  $\text{Co}_3\text{O}_4/\text{FLG}$  nanocomposite GDE exhibited a high activity of 0.9 V at a current density of  $100 \text{ A m}^{-2}$ , 50%

energy savings, and an approximately one fold enhancement compared with those of pure  $\text{Co}_3\text{O}_4$  and FLG electrodes,  $\text{Co}_3\text{O}_4/\text{C}$  GDE, and  $\text{MnO}_2/\text{FLG}$  GDE. The  $\text{Co}_3\text{O}_4/\text{FLG}$  nanocomposite GDE also displayed better durability in an acid solution (100 h at  $100 \text{ A m}^{-2}$  in  $120 \text{ g L}^{-1} \text{ MnSO}_4 + 30 \text{ g L}^{-1} \text{ H}_2\text{SO}_4$ ) than the Pt-free GDE.
