# Perovskite lattice oxygen contributes to low-temperature catalysis for exhaust gas cleaning†

Takuma Higo,<sup>a</sup> Kohei Ueno,<sup>a</sup> Yuki Omori,<sup>a</sup> Hiroto Tsuchiya,<sup>a</sup> Shuhei Ogo,<sup>a</sup> Satoshi Hirose,<sup>b</sup> Hitoshi Mikami<sup>b</sup> and Yasushi Sekine<sup>a</sup>

A Pd catalyst supported on Ba-substituted LaAlO<sub>3</sub> perovskite (Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>) was investigated for NO reduction at low temperature by propylene, which revealed that Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> has remarkably higher activity than other Pd catalysts at low temperatures (≤573 K) for NO reduction by propylene. To elucidate the surface reaction pathway, transient response tests were conducted using <sup>18</sup>O<sub>2</sub>. Also, X-ray photoelectron spectroscopy (XPS) and diffuse reflectance infrared Fourier transform spectroscopy (DRIFTS) measurements were conducted. Comparison with a Ba-impregnated catalyst (Pd/Ba/LaAlO<sub>3</sub>) demonstrated that Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> shows higher activity for the formation of oxygenated species (C<sub>x</sub>H<sub>y</sub>O<sub>z</sub>) as an intermediate for NO reduction because the surface lattice oxygen has improved mobility via Ba<sup>2+</sup> substitution in LaAlO<sub>3</sub>. Therefore, Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> have high activity for NO reduction, even at low temperatures in a humid condition.

## 1. Introduction

Additional and increasingly severe emissions and fuel efficiency regulations are expected to be imposed on automobiles along with the global progress of motorization. In spite of the development for zero-emission vehicles (ZEVs) such as battery electric vehicles (BEVs) and fuel cell vehicles (FCVs), it is considered that internal combustion engine vehicles including plug-in hybrid vehicles (PHVs) will maintain a certain share of future vehicle markets. Therefore, purification of emission gases from gasoline combustion vehicles will remain an important technology in a future sustainable society. Currently, the most general technology for purifying the emission gases of gasoline combustion vehicles is conversion of pollutants using a three-way catalyst (TWC). On TWCs, reduction of nitrogen oxides (NO<sub>x</sub>), oxidation of unburned hydrocarbons (HC) and carbon monoxide (CO) proceed simultaneously through conversion respectively to N<sub>2</sub>, CO<sub>2</sub>, and H<sub>2</sub>O.<sup>1,2</sup> Such catalysts can convert the pollutants in emissions by nearly 100% at the stoichiometric air/fuel ratio and at high temperatures (>673 K).<sup>3</sup> One challenge for future TWCs is high catalytic performance at lower temperatures than those of the current standard operation conditions.

Pd-based catalysts show higher activity for HC oxidation than those of either Pt and Rh, but the NO<sub>x</sub> reduction activity is

poor.<sup>4,5</sup> Many studies have been conducted to enhance the catalytic performance for Pd-based catalysts, with the addition of a promoter (alkali,<sup>6,7</sup> alkaline earth,<sup>8</sup> rare-earth<sup>8,9</sup> *etc.*) or using bimetallic catalysts,<sup>10,11</sup> and the development of support materials.<sup>12–22</sup> Further increase in achieving catalytic activity at lower temperatures is anticipated.

The combination of noble metals and perovskite-type oxide has been studied as offering potential for effective de-NO<sub>x</sub> catalysts.<sup>15,18–22</sup> A typical formula of the perovskite structure is ABO<sub>3</sub>. Perovskite oxides have been regarded as interesting catalyst supports because of their features, which include redox property and high thermal stability.<sup>15,20,23,24</sup> Results have shown that the lattice oxygen reacts with various hydrocarbons to form partially oxidized hydrocarbon species (C<sub>x</sub>H<sub>y</sub>O<sub>z</sub>: oxygenated species) on Sr-substituted LaAlO<sub>3</sub>.<sup>25–27</sup> Oxygenated species reacted with H<sub>2</sub>O as reductants to form H<sub>2</sub>. Then the lattice oxygen consumed is restored by H<sub>2</sub>O in atmosphere. Such a redox cycle of substituted LaAlO<sub>3</sub> support is regarded as effective for NO reduction with hydrocarbon.

This study investigated Ba-substituted LaAlO<sub>3</sub> perovskite as a support material for Pd catalyst for low-temperature NO<sub>x</sub> reduction by propylene. We confirmed the superiority of Pd catalyst supported on Ba-substituted perovskite and discussed factors related to its high catalytic performance.

## 2. Experimental

### 2.1 Catalyst preparation

Perovskite-type oxides (LaAlO<sub>3</sub>, La<sub>1-x</sub>Ba<sub>x</sub>AlO<sub>3-δ</sub>; x = 0.03, 0.05, 0.1 and 0.2) were prepared using a citric acid complex method.<sup>25</sup> Metal nitrate precursors (Kanto Chemical Co. Inc.) were

<sup>a</sup>Department of Applied Chemistry, Waseda University, 3-4-1, Okubo, Shinjuku, Tokyo 169-8555, Japan. E-mail: t-higo@aoni.waseda.jp

<sup>b</sup>Honda R&D, 4630, Shimo-Takanezawa, Tochigi 321-3393, Japan

† Electronic supplementary information (ESI) available. See DOI: 10.1039/c9ra03050f

dissolved in water. Then, excess citric acid and ethylene glycol (Kanto Chemical Co. Inc.) were added to the solution. The molar ratio of metal : citric acid : ethylene glycol was 1 : 3 : 3. After the obtained solution was evaporated in a water bath at *ca.* 353 K for 16 h, the solution was dried on a hot plate with stirring. The obtained powder was pre-calcined at 673 K for 2 h and was calcined at 1123 K for 10 h.

We prepared Pd-loaded catalysts using an impregnation method. For loading Pd, palladium acetate (Kanto Chemical Co. Inc.) was used as a precursor. Distilled acetone was used as a solvent. The Pd loading amount was 0.5 wt%. The prepared catalysts were calcined at 823 K for 3 h in air.

We prepared Pd/Ba/LaAlO<sub>3</sub> using sequential impregnation of Ba and Pd. The Ba loading amount was 6.5 wt% (which is almost equal to the molar ratio of Ba in Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>). As a control catalyst, 0.53 wt% Pd/Al<sub>2</sub>O<sub>3</sub> (Honda R&D Co. Ltd.) was used. γ-Al<sub>2</sub>O<sub>3</sub> was prepared as support by calcination of boehmite (Sasol Ltd.) in air at 873 K. Loading of Pd was conducted using an ion-exchange method. Palladium nitrate (Kojima Chemicals Co. Ltd.) was used as a precursor. Calcination was conducted at 773 K in air for 2 h.

## 2.2 Activity tests

Catalytic activity tests for NO reduction were conducted in a fixed bed quartz reactor at atmospheric pressure. Catalysts (50 mg, 0.25–0.5 mm particle size) were mixed with SiC to reach a catalyst bed height of 1 cm. Activity tests were conducted in reaction gases of three compositions balanced by Ar gas: NO–C<sub>3</sub>H<sub>6</sub> (2250 ppm NO, 250 ppm C<sub>3</sub>H<sub>6</sub>, λ = 1), NO–C<sub>3</sub>H<sub>6</sub>–O<sub>2</sub> (1000 ppm NO, 500 ppm C<sub>3</sub>H<sub>6</sub>, 2000 ppm O<sub>2</sub>, λ = 1.11), and NO–C<sub>3</sub>H<sub>6</sub>–O<sub>2</sub>–H<sub>2</sub>O (1000 ppm NO, 500 ppm C<sub>3</sub>H<sub>6</sub>, 2000 ppm O<sub>2</sub>, 7 vol% H<sub>2</sub>O, λ = 1.11). The λ value is defined as eqn (1).

$$\lambda = \frac{[\text{NO}] + 2[\text{O}_2]}{9[\text{C}_3\text{H}_6]} \quad (1)$$

The total gas flow rate for the reaction was 200 mL min<sup>-1</sup> (W/F = 0.1 g h mol<sup>-1</sup>). Pre-treatment of the catalyst was conducted sequentially for oxidation (5% O<sub>2</sub>, Ar balanced at 773 K for 15 min) and reduction (5% H<sub>2</sub>, Ar balanced at 773 K for 15 min). Then catalytic activities were measured at 673, 623, 573, 523, and 473 K. The outlet gas was analyzed using online GC-TCD (GC-8A; Shimadzu Corp.), GC-FID (GC-8A; Shimadzu Corp.) and a chemiluminescent method NO<sub>x</sub> analyser (NOA-7000; Shimadzu Corp.). The NO conversion and N<sub>2</sub> yield are defined as shown below (eqn (2) and (3)).

$$\text{NO conversion (\%)} = \frac{(\text{inlet rate of NO}) - (\text{outlet rate of NO})}{(\text{inlet rate of NO})} \times 100 \quad (2)$$

$$\text{N}_2 \text{ yield} = \frac{2 \times (\text{formation rate of N}_2)}{(\text{inlet rate of NO})} \times 100 \quad (3)$$

Tests for dependence on NO and C<sub>3</sub>H<sub>6</sub> concentration were conducted in NO–C<sub>3</sub>H<sub>6</sub>–O<sub>2</sub>–H<sub>2</sub>O condition at 523 K. The loaded amount of Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> was decreased to 25 mg to obtain kinetic values. The reaction gas composition for investigation of NO was NO (500, 750, 1000, 1250, or 1500 ppm): C<sub>3</sub>H<sub>6</sub> 500 ppm: O<sub>2</sub> 2000 ppm. The reaction gas composition for investigation of C<sub>3</sub>H<sub>6</sub> was NO 1000 ppm: C<sub>3</sub>H<sub>6</sub> (375, 425, 500, 575, 625, or 750 ppm): O<sub>2</sub> 2000 ppm. 7 vol% H<sub>2</sub>O was fed in both reaction conditions.

## 2.3 Characterization of catalysts

X-ray diffraction patterns were measured to confirm the crystalline structure of perovskite-type oxides (SmartLab 3; Rigaku Corp.). The Cu Kα radiation condition was at 40 kV and 40 mA. The respective BET specific surface areas of the catalysts were measured at 77 K using N<sub>2</sub> adsorption (GeminiVII; Micromeritics Instrument Corp.). Using a field emission transmission electron microscope equipped with an energy dispersive X-ray spectrometer (TEM-EDX, JEM-2100F; JEOL Ltd.), we evaluated the Pd particle sizes of Pd/Al<sub>2</sub>O<sub>3</sub>, Pd/LaAlO<sub>3</sub>, Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> and Pd/Ba/LaAlO<sub>3</sub> after oxidation (5% O<sub>2</sub>, Ar balance at 773 K for 15 min) and reduction (5% H<sub>2</sub>, Ar balance at 773 K for 15 min) as pre-treatments.

## 2.4 In situ DRIFTS measurements

*In situ* DRIFTS measurements were taken using a Fourier transform infrared spectrometer (FT/IR 6200; Jasco Corp.) with an MCT detector and a ZnSe window. Catalyst sample powder (*ca.* 40 mg) was filled into a sample cell. After background (denoted as BKG) measurements were taken under inert Ar gas (100 mL min<sup>-1</sup> at each temperature) after oxidation (5% O<sub>2</sub> for 15 min) and reduction (5% H<sub>2</sub> for 15 min) at 773 K, the following two measurements were taken.

(1) Steady state measurement: reactant gases (NO 1000 ppm, O<sub>2</sub> 2000 ppm, C<sub>3</sub>H<sub>6</sub> 500 ppm, H<sub>2</sub>O 7 vol% and Ar balanced) were supplied to the sample cell for 10 min at each temperature (473–623 K). Each spectrum was recorded from 1000 to 4000 cm<sup>-1</sup> with resolution of 4.0 cm<sup>-1</sup> and accumulation of 10 scans.

(2) Transient measurement: C<sub>3</sub>H<sub>6</sub>-containing gas (C<sub>3</sub>H<sub>6</sub> 500 ppm and Ar) is supplied to the sample cell for 10 min at 523 K. Then, oxidant gases (O<sub>2</sub> 2000 ppm or NO 1000 ppm and Ar) were supplied for 10 min after Ar purging for 10 min. This procedure was regarded as one operation. Two operations were conducted continuously. The change of spectrum was recorded from 1000 to 4000 cm<sup>-1</sup> with resolution of 4.0 cm<sup>-1</sup> and accumulation of 10 scans.

## 2.5 Transient response tests using <sup>18</sup>O<sub>2</sub>

Transient response tests using <sup>18</sup>O<sub>2</sub> were done to observe the contribution of lattice oxygen to the reaction. Catalyst of 200 mg was used for this test. Pretreatment was conducted similarly to the activity test. The feed gas was supplied for 15 min at 523 K after Ar purging for 5 min. The gas composition was 500 ppm C<sub>3</sub>H<sub>6</sub>: 2000 ppm <sup>18</sup>O<sub>2</sub> (balance gas was Ar; 200 mL min<sup>-1</sup> total flow rate). The outlet gas was analysed using a quadrupole mass spectrometer (QGA; Hiden Analytical Ltd.). The analysis

references of  $Q$ -mass for carbon dioxide species were  $m/z = 44(\text{C}^{16}\text{O}_2)$ ,  $46(\text{C}^{16}\text{O}^{18}\text{O})$ , and  $48(\text{C}^{18}\text{O}_2)$ . Here,  $^{16}\text{O}$  detected in carbon dioxide was regarded as the amount of lattice oxygen used in the reaction.

## 2.6 X-ray photoelectron spectroscopy (XPS)

To obtain data for the surface atomic ratio and the spectra of O1s region of the catalysts, XPS measurements were performed on Versa Probe II (Ulvac Phi Inc.) with Al  $K\alpha$  X-rays. Binding energies for each orbital were calibrated using C1s (284.8 eV). Catalysts were treated using the following procedure before XPS measurements. After heating treatment in Ar gas flow at 773 K for 30 min, samples were exposed sequentially in the order of 500 ppm  $\text{C}_3\text{H}_6$  (step 1), 2000 ppm  $\text{O}_2$  (step 2), and 500 ppm  $\text{C}_3\text{H}_6$  (step 3) flow at 523 K. To remove  $\text{C}_3\text{H}_6$  or  $\text{O}_2$  from the sample cell, purging with Ar gas was performed for 10 min between the respective steps. Samples after each step were cooled to room temperature in Ar flow and were moved to the sample chamber using a transfer vessel to avoid exposure to air.

## 3. Results and discussion

### 3.1 Catalytic performance and structure of substituted perovskite supported Pd catalyst

We investigated NO reduction by propylene as a model of unburned hydrocarbon in an exhaust gas on various Pd catalysts supported on perovskites (Pd/LaAlO<sub>3</sub>, Pd/Ba/LaAlO<sub>3</sub>, Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3- $\delta$</sub> ) and Pd/Al<sub>2</sub>O<sub>3</sub> as a control catalyst for comparison. The respective catalytic activities on these catalysts are presented in Fig. 1, S1 and Table S1 of ESI.† At low temperatures of 523–573 K, Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3- $\delta$</sub>  catalyst showed higher NO conversion and N<sub>2</sub> yield than the other catalysts. Table S2† shows results for the BET specific surface area, mean particle diameter and turnover frequency (TOF) for NO conversion at 523 K on the catalysts. The mean particle diameter was estimated from the Pd particle size histogram of TEM measurements (Fig. S2†). The TOF was calculated on the assumption that Pd particles are supported hemispherically. The value of TOF for Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3- $\delta$</sub>  was the highest among these catalysts under this condition. To investigate the appropriate amount of Ba substitution in the LaAlO<sub>3</sub> support, we

evaluated the catalytic performances of various Ba-substituted catalysts (Pd/La<sub>1- $x$</sub> Ba <sub>$x$</sub> AlO<sub>3- $\delta$</sub> ;  $x = 0, 0.03, 0.05, 0.1$  and  $0.2$ ). Fig. S3† presents the results. Among these catalysts, Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3- $\delta$</sub>  showed the best NO conversion. Therefore, we determined the appropriate substitution ratio of La with Ba as 10%. The XRD pattern and the lattice constant for each Ba-substituted LaAlO<sub>3</sub> are presented in Fig. S4 and S5†.

In other conditions, we compared the catalytic activities on NO-C<sub>3</sub>H<sub>6</sub> reaction in a stoichiometric condition and a slightly lean condition without steam. Tables S3 and S4† present NO conversions on various catalysts at each temperature. Regarding NO-C<sub>3</sub>H<sub>6</sub> reaction without O<sub>2</sub> and H<sub>2</sub>O (NO, 2250 ppm; C<sub>3</sub>H<sub>6</sub>, 250 ppm), NO conversion over the catalysts at 523 K were 23.9% for Pd/Al<sub>2</sub>O<sub>3</sub>, 29.5% for Pd/LaAlO<sub>3</sub>, 44.3% for Pd/Ba/LaAlO<sub>3</sub> and 46.5% for Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3- $\delta$</sub> . Results show that Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3- $\delta$</sub>  and Pd/Ba/LaAlO<sub>3</sub> have similarly high activities at 523 K. From earlier studies, the effects of promoter co-impregnated or sequentially impregnated on the catalytic activity were reported for PGM catalysts for NO<sub>x</sub> reduction.<sup>6–9,28–31</sup> Reportedly, basic additives such as Na and Ba showed promotive effects on NO-C<sub>3</sub>H<sub>6</sub> reaction.<sup>6,7</sup> These results demonstrate that Ba species promote NO reduction by C<sub>3</sub>H<sub>6</sub>, irrespective of substitution or impregnation. However, the catalytic activity of Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3- $\delta$</sub>  (*i.e.* Ba substituted catalyst) under a slightly lean condition was much higher than Pd/Ba/LaAlO<sub>3</sub>, as shown in Tables S1 (with H<sub>2</sub>O) and S4 (without H<sub>2</sub>O).† Under these conditions, Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3- $\delta$</sub>  is a promising catalyst for NO<sub>x</sub> reduction.

### 3.2 In situ DRIFTS studies for steady-state surface species

To elucidate the reasons for high activity at low temperature with steam on Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3- $\delta$</sub>  (*i.e.* Ba-substituted perovskite support) catalyst in terms of a reaction mechanism, *in situ* DRIFTS measurements were conducted for various catalysts. Fig. 2 presents DRIFT spectra of surface species on Pd/

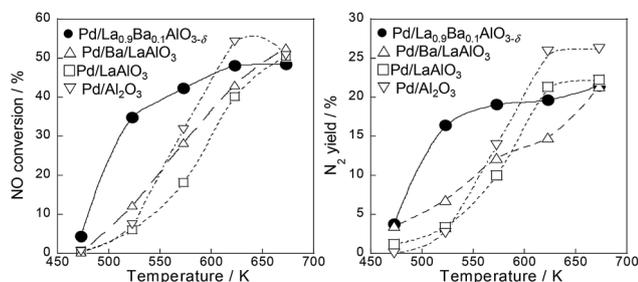

Fig. 1 Comparison of NO conversions and N<sub>2</sub> yields over Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3- $\delta$</sub> , Pd/Ba/LaAlO<sub>3</sub>, Pd/LaAlO<sub>3</sub> and Pd/Al<sub>2</sub>O<sub>3</sub>. Reaction conditions: total flow rate = 200 mL min<sup>-1</sup>, NO 1000 ppm, C<sub>3</sub>H<sub>6</sub> 500 ppm, O<sub>2</sub> 2000 ppm, H<sub>2</sub>O 7 vol%.

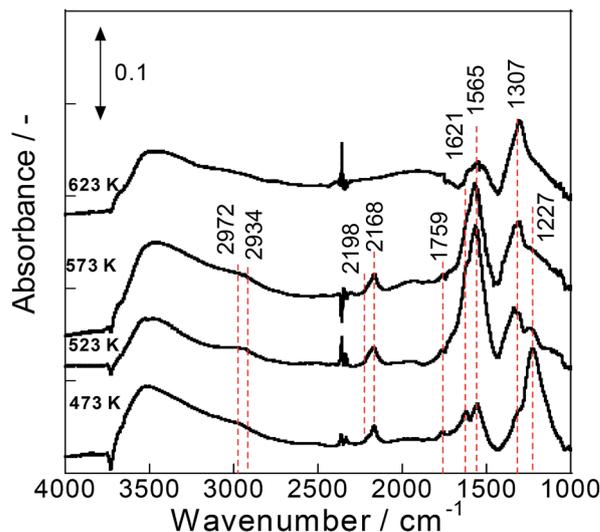

Fig. 2 IR spectra of surface species on Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3- $\delta$</sub>  during NO + C<sub>3</sub>H<sub>6</sub> + O<sub>2</sub> + H<sub>2</sub>O reaction at 473 K, 523 K, 573 K and 623 K.

$\text{La}_{0.9}\text{Ba}_{0.1}\text{AlO}_{3-\delta}$ . These spectra had two notable regions at  $1100\text{--}1800\text{ cm}^{-1}$  and  $2100\text{--}3000\text{ cm}^{-1}$ . The notable band at  $1227\text{ cm}^{-1}$  assignable to nitrite species<sup>32</sup> was observed at all temperatures. The relative intensity of the nitrite band decreased concomitantly with increasing temperature. The other strong bands at  $1307$  and  $1500\text{--}1800\text{ cm}^{-1}$  are overlapping bands derived from various surface species. These bands in this region are assigned to partially oxidized hydrocarbons, carbonate and nitrate species.<sup>32–37</sup> The presence of weak bands near  $2800\text{--}3000\text{ cm}^{-1}$  assignable to C–H stretching<sup>32,37</sup> revealed the existence of hydrocarbon fragments on the catalyst surface. The relative intensity of these bands increased at temperatures up to  $523\text{ K}$  and decreased at temperatures higher than  $573\text{ K}$ . In addition to the bands described above, notable bands at  $2168\text{ cm}^{-1}$  and  $2198\text{ cm}^{-1}$  were observed and assigned to isocyanate ( $\text{NCO}$ ) species.<sup>32–35,37,38</sup> These bands of isocyanate appeared clearly from  $473\text{ K}$  to  $573\text{ K}$ , and disappeared at  $623\text{ K}$ . Earlier reports describe the surface isocyanate species as the intermediate species on various  $\text{NO}_x$  reduction pathways.<sup>33,34,37,38</sup> However, Burch *et al.* reported that isocyanate species is not a key intermediate but is instead a spectator.<sup>39</sup> We infer that isocyanate, which contains N and C, is an indicator of the surface reaction of NO and hydrocarbon reductant. From observation of the spectra for  $\text{Pd}/\text{La}_{0.9}\text{Ba}_{0.1}\text{AlO}_{3-\delta}$ , the reaction pathway under this condition can be inferred as follows: NO adsorbs on the Ba species near Pd particles as bridging nitrite and nitrate species. Also,  $\text{C}_3\text{H}_6$  is oxidized to form  $\text{C}_x\text{H}_y\text{O}_z$ . The nitrite/nitrate and  $\text{C}_x\text{H}_y\text{O}_z$  are the active intermediate species, which mutually react to form isocyanate. The isocyanate reacts with NO to convert to  $\text{N}_2$ ,  $\text{CO}_2$  and  $\text{H}_2\text{O}$  as final products. The DRIFT spectra for  $\text{Pd}/\text{Ba}/\text{LaAlO}_3$  are depicted in Fig. S6†. The assignment and behaviour for the bands on spectra closely resemble those for  $\text{Pd}/\text{La}_{0.9}\text{Ba}_{0.1}\text{AlO}_{3-\delta}$ . Therefore, the results suggest that the surface intermediate species during steady state reactions on  $\text{Pd}/\text{La}_{0.9}\text{Ba}_{0.1}\text{AlO}_{3-\delta}$  and  $\text{Pd}/\text{Ba}/\text{LaAlO}_3$  are almost identical under this condition.

Next, we investigated the DRIFT spectra on  $\text{Pd}/\text{Al}_2\text{O}_3$  as a control catalyst support at various temperatures in the  $\text{NO-C}_3\text{H}_6\text{-O}_2\text{-H}_2\text{O}$  condition ( $1000\text{ ppm NO} + 500\text{ ppm C}_3\text{H}_6 + 2000\text{ ppm O}_2 + 7\text{ vol\% H}_2\text{O}$ ). Results are shown in Fig. S7†. The bands assigned to acetate species ( $1578$  and  $1455\text{ cm}^{-1}$ ) were observed at widely various temperatures. The results for this species on  $\text{Al}_2\text{O}_3$  surface show good accordance with those explained in earlier reports.<sup>32–34</sup> The band at  $1647\text{ cm}^{-1}$  is an overlapped band of two-fold NO<sup>35</sup> on Pd surface and bending mode of  $\text{H}_2\text{O}$ . Moreover some weak bands assignable to formate ( $1375$  and  $2900\text{--}3000\text{ cm}^{-1}$ ) and isocyanate ( $\text{NCO}$ ;  $2217\text{ cm}^{-1}$ ) were observed. Nitrite ( $\text{NO}_2^-$ ) and nitrate ( $\text{NO}_3^-$ ) species were not observed. At  $623\text{ K}$ , the acetate band intensity became very weak. A strong band assigned to bidentate nitrate ( $1548\text{ cm}^{-1}$ ) appeared by accumulation on  $\text{Al}_2\text{O}_3$ .<sup>34,36</sup> This behaviour suggests that acetate species reacted with NO on the Pd surface. Many research groups have reported the role of acetate as an essential reductant.<sup>33,34</sup> Our DRIFTS results agreed well with earlier reports for  $\text{Al}_2\text{O}_3$ -based catalysts on NO reduction by  $\text{C}_3\text{H}_6$  in the presence of  $\text{O}_2$ .<sup>32–36</sup> Fig. S8† presents DRIFT spectra for  $\text{Pd}/\text{LaAlO}_3$ , *i.e.* no Ba on the catalyst surface. On the Pd/

$\text{LaAlO}_3$ , the spectra were unclear. Moreover, the band intensity was low. The evident adsorbed species were NO adsorbed onto Pd ( $1667$ ,  $1731\text{ cm}^{-1}$ ) and isocyanate ( $2169$ ,  $2194\text{ cm}^{-1}$ ). On this catalyst, nitrite ( $1286\text{ cm}^{-1}$ ) is a spectator because its intensity was not changed at high temperatures. Therefore, results suggest that the reaction in steady state on  $\text{Pd}/\text{LaAlO}_3$  is similar to that on  $\text{Pd}/\text{Al}_2\text{O}_3$ .

### 3.3 Conversion rate dependence on NO and $\text{C}_3\text{H}_6$ concentration

To clarify details of the reaction mechanism, the dependence of the reaction rate at  $523\text{ K}$  on the concentration of NO or  $\text{C}_3\text{H}_6$  was investigated for  $\text{Pd}/\text{La}_{0.9}\text{Ba}_{0.1}\text{AlO}_{3-\delta}$  and  $\text{Pd}/\text{Ba}/\text{LaAlO}_3$ . The dependence of the conversion rates on NO concentration are shown in Fig. S9†. No clear dependence of the conversion rates was found for any component on NO concentration, as shown in Fig. S9†. It was expected that the adsorption or activation of NO was sufficiently fast on these catalysts because the Ba species on surface promote the adsorption of NO as  $\text{NO}_2^-$  and  $\text{NO}_3^-$ . Results of the dependence on  $\text{C}_3\text{H}_6$  concentration are presented in Fig. 3. In the lean region, the conversion rate of NO on both catalysts positively depended on  $\text{C}_3\text{H}_6$  concentration. Apparently, the conversion rate dependences of  $\text{C}_3\text{H}_6$  and  $\text{O}_2$  were low. However, the dependence on  $\text{C}_3\text{H}_6$  concentration presented remarkably different trends on  $\text{Pd}/\text{La}_{0.9}\text{Ba}_{0.1}\text{AlO}_{3-\delta}$  and  $\text{Pd}/\text{Ba}/\text{LaAlO}_3$  in a rich region. On  $\text{Pd}/\text{Ba}/\text{LaAlO}_3$ , the conversion rate of all feeds clearly showed negative dependence on the  $\text{C}_3\text{H}_6$  concentration. However, in the case of  $\text{Pd}/\text{La}_{0.9}\text{Ba}_{0.1}\text{AlO}_{3-\delta}$ , positive dependence was shown. Comparison of these results with those for  $\text{Pd}/\text{LaAlO}_3$  in Fig. S10† reveals that the effect of surface Ba species can be regarded as described below. On  $\text{Pd}/\text{LaAlO}_3$ , the reaction of NO and  $\text{C}_3\text{H}_6$  is affected by the competitive adsorption of these reactants because there is no adsorption site other than Pd. The dependence on  $\text{C}_3\text{H}_6$  concentration for  $\text{Pd}/\text{LaAlO}_3$  showed negative dependence under the same experimental conditions.  $\text{C}_3\text{H}_6$  strongly adsorbing on Pd inhibits the adsorption of NO. This assumption agrees with an earlier report of the literature.<sup>6</sup> The surface Ba species on  $\text{Pd}/\text{Ba}/\text{LaAlO}_3$  and  $\text{Pd}/\text{La}_{0.9}\text{Ba}_{0.1}\text{AlO}_{3-\delta}$  play an important role as alternative adsorption sites for NO in avoiding

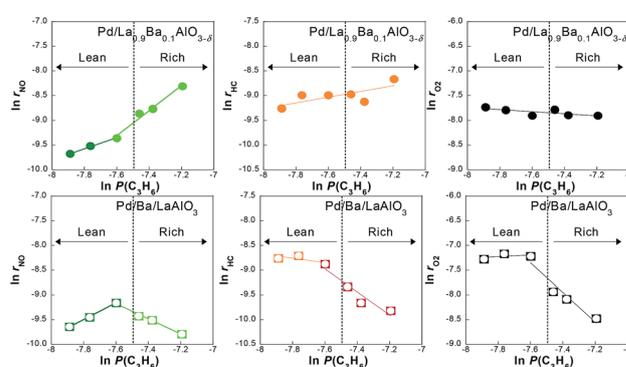

Fig. 3 Dependence of the reaction rate on the partial pressure of  $\text{C}_3\text{H}_6$  on  $\text{Pd}/\text{La}_{0.9}\text{Ba}_{0.1}\text{AlO}_{3-\delta}$  and  $\text{Pd}/\text{Ba}/\text{LaAlO}_3$  at  $523\text{ K}$  during  $\text{NO-C}_3\text{H}_6\text{-O}_2\text{-H}_2\text{O}$  reaction.

the competitive adsorption of NO and C<sub>3</sub>H<sub>6</sub>. Furthermore, nitrite on Ba species is an effective intermediate for NO reduction by C<sub>3</sub>H<sub>6</sub>. On Ba-containing catalysts, it is considered that the reaction pathway changes to the route *via* nitrite and C<sub>x</sub>H<sub>y</sub>O<sub>z</sub>, which can proceed efficiently at lower temperatures. However, at high C<sub>3</sub>H<sub>6</sub> concentrations, NO conversion on Pd/Ba/LaAlO<sub>3</sub> was inhibited by the strong adsorption of C<sub>3</sub>H<sub>6</sub>. This result suggests that, because C<sub>3</sub>H<sub>6</sub> occupied Pd surface of Pd/Ba/LaAlO<sub>3</sub> and C<sub>3</sub>H<sub>6</sub> oxidation by O<sub>2</sub> is inhibited, the C<sub>x</sub>H<sub>y</sub>O<sub>z</sub> formation does not occur so rapidly. Consequently, the rate of NO reduction by C<sub>x</sub>H<sub>y</sub>O<sub>z</sub> also decreases because the formation rate of C<sub>x</sub>H<sub>y</sub>O<sub>z</sub> decreases. In contrast, no inhibition phenomenon occurs on Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> because the adsorbed species derived from C<sub>3</sub>H<sub>6</sub> was oxidized rapidly. Comparison of both catalysts suggests that the oxidation of C<sub>3</sub>H<sub>6</sub> was promoted on Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> compared with Pd/Ba/LaAlO<sub>3</sub>.

### 3.4 Role of surface lattice oxygen of Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>

From investigation of the conversion rate dependence, results demonstrated that C<sub>3</sub>H<sub>6</sub> oxidation is the important factor on Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>. It is inferred that pathways for the formation of the intermediates derived from C<sub>3</sub>H<sub>6</sub> differ among Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> and Pd/Ba/LaAlO<sub>3</sub>. In our earlier studies of steam reforming of toluene over Ni catalyst supported on Sr-substituted LaAlO<sub>3</sub> (La<sub>0.7</sub>Sr<sub>0.3</sub>AlO<sub>3-δ</sub>),<sup>26,27</sup> we reported that hydrocarbons were oxidized by the lattice oxygen of La<sub>0.7</sub>Sr<sub>0.3</sub>AlO<sub>3-δ</sub>. The lattice oxygen of La<sub>0.7</sub>Sr<sub>0.3</sub>AlO<sub>3-δ</sub>, having high mobility, can contribute to the surface reaction *via* release and restoration. Therefore, we investigated the contribution of surface lattice oxygen to the formation of oxidized C<sub>3</sub>H<sub>6</sub> species by transient response test using <sup>18</sup>O<sub>2</sub>, XPS and DRIFTS measurements. To confirm the release of surface lattice oxygen, we conducted the transient response test using <sup>18</sup>O<sub>2</sub> according to the procedures described in Section 2. The test results are presented in Fig. 4 and Table 1. After gas switching, C<sup>16</sup>O<sub>2</sub> and C<sup>16</sup>O<sup>18</sup>O were observed on Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>. Formation of these <sup>16</sup>O-containing products indicates that C<sub>3</sub>H<sub>6</sub> is oxidized by lattice oxygen of La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>. The amount of <sup>16</sup>O detected during the test is 91 μmol per 200 mg catalyst, which has 2753 μmol of lattice oxygen. Particularly, 45.4 μmol of <sup>16</sup>O was released as the C<sup>16</sup>O<sub>2</sub> during this test. This value is comparable

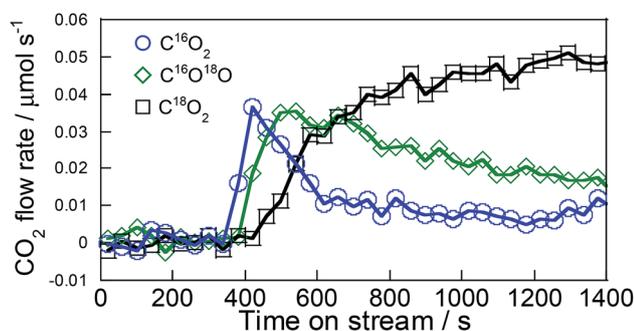

Fig. 4 Transient response curves for typical products on Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> following Ar → C<sub>3</sub>H<sub>6</sub> + <sup>18</sup>O<sub>2</sub> switch at 523 K.

Table 1 Amount of carbon dioxide species detected during transient response tests

	C <sup>16</sup> O <sub>2</sub> /μmol	C <sup>16</sup> O <sup>18</sup> O/μmol	C <sup>18</sup> O <sub>2</sub> /μmol
Pd/La <sub>0.9</sub> Ba <sub>0.1</sub> AlO <sub>3-δ</sub>	22.7	45.6	51.8

to the amount of surface lattice oxygen of about 1–2 layer(s). We estimated the amount of surface lattice oxygen on (100) or (110) to be 32 μmol or 22 μmol per 200 mg from BET surface area and lattice structure of La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>. These <sup>16</sup>O-containing products were detected before C<sup>18</sup>O<sub>2</sub>. Therefore, the surface lattice oxygen of La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> is considered to react to C<sub>3</sub>H<sub>6</sub> faster than <sup>18</sup>O species derived from adsorbed <sup>18</sup>O<sub>2</sub> on surface of Pd. The results for Pd/Ba/LaAlO<sub>3</sub> are presented in Fig. S11 and Table S5;† the C<sup>16</sup>O<sub>2</sub> formation amount was only 6.5 μmol during this test. Therefore, only a small amount of the surface lattice oxygen of Pd/Ba/LaAlO<sub>3</sub> contributed to C<sub>3</sub>H<sub>6</sub> oxidation during this test. Additionally, because of high mobility of surface lattice oxygen of La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>, on Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>, the peak of MS signal for C<sup>16</sup>O<sub>2</sub> was detected 90 s faster than on Pd/Ba/LaAlO<sub>3</sub>.

We conducted XPS measurements of these catalysts with treatment according to the following procedure. First, the heat treatment in Ar flow for 30 min at 773 K. Then, at 523 K, the catalysts were alternately exposed to 500 ppm C<sub>3</sub>H<sub>6</sub> flow or O<sub>2</sub> flow diluted with Ar for 15 min each. The flow order is C<sub>3</sub>H<sub>6</sub> (step 1) → O<sub>2</sub> (step 2) → C<sub>3</sub>H<sub>6</sub> (step 3). To remove C<sub>3</sub>H<sub>6</sub> and O<sub>2</sub> from sample cell, purging with Ar gas was performed for 10 min between the respective treatments. XP spectra of O1s region for Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> after each treatment are shown in Fig. 5. On the spectra, O1s region had four components corresponding to various oxygen species as O<sub>I</sub> (at 528.9–529.1 eV), O<sub>II</sub> (at 530.1–530.2 eV), O<sub>III</sub> (at 531.1–531.5 eV) and O<sub>IV</sub> (at 532.3–532.7 eV). The binding energies of these peaks and the ratios of O<sub>x</sub>/La are presented in Table 2. The O<sub>I</sub> is assigned to O<sup>2-</sup> as lattice oxygen

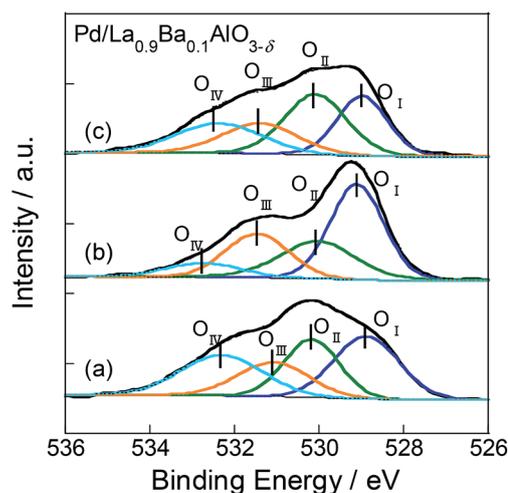

Fig. 5 XP spectra of O1s for Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> (a) after exposure in C<sub>3</sub>H<sub>6</sub> flow, (b) after exposure in O<sub>2</sub> and (c) after exposure of C<sub>3</sub>H<sub>6</sub> flow again.

**Table 2** Binding energy and surface atomic ratio of O1s region of XP spectra for Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>

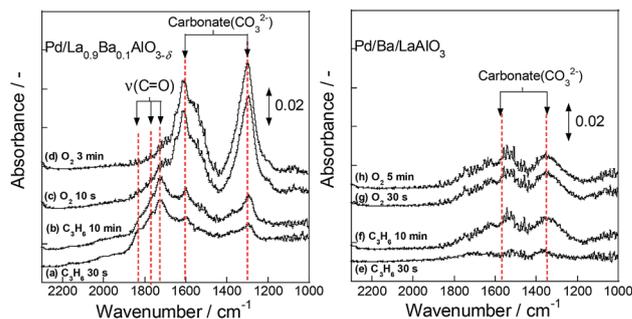

Spectrum	Binding energy/eV				O <sub>I</sub> /La	O <sub>II</sub> /La	O <sub>III</sub> /La	O <sub>IV</sub> /La
	O <sub>I</sub>	O <sub>II</sub>	O <sub>III</sub>	O <sub>IV</sub>				
(a)	528.9	530.2	531.1	532.3	2.3	1.8	1.6	1.9
(b)	529.1	530.2	531.5	532.7	3.0	1.7	1.6	0.6
(c)	529.0	530.1	531.4	523.4	2.0	2.5	1.5	1.6

of La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>.<sup>40–42</sup> The O<sub>II</sub> assigned to O<sup>-</sup>, which is a superficial chemisorbed or lattice oxygen species.<sup>40–42</sup> We infer that O<sup>-</sup> is the intermediate species for the release and restoration of lattice oxygen according to the following scheme.<sup>1,43</sup>

The O<sub>III</sub> and O<sub>IV</sub> are attributed to adsorbed carbonate<sup>40,42,44</sup> and C=O(COOR).<sup>45</sup> The appearance of O<sub>IV</sub> suggests that a oxygenated hydrocarbon species adsorbed onto the surface. The spectra changed drastically for each step in the procedure of the experiment on Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>. In spectrum (b), increase of O<sub>I</sub> and decrease of O<sub>IV</sub> were observed. These behaviours indicated the restoration of O<sup>2-</sup> as lattice oxygen and the total oxidation of adsorbed hydrocarbon species by O<sub>2</sub> treatment. Furthermore, in spectrum (c), the amounts of O<sub>I</sub> and O<sub>IV</sub> changed, and the values were close to those in spectrum (a). Partial oxidation of C<sub>3</sub>H<sub>6</sub> probably occurred by lattice oxygen, which was restored by O<sub>2</sub> treatment. However, as shown in the results for Pd/Ba/LaAlO<sub>3</sub> in Fig. S12 and Table S6†, the respective intensities of O<sub>I</sub> and O<sub>IV</sub> were only slightly changed at each step. Only O<sub>II</sub> increased in step 2 because the adsorbed oxygen on Pd was increased by O<sub>2</sub> treatment. These results indicate that the surface lattice oxygen on Pd/Ba/LaAlO<sub>3</sub> does not contribute to C<sub>3</sub>H<sub>6</sub> oxidation to any considerable degree. From the results described above, we confirmed the release and restoration of the surface lattice oxygen during the oxidation of C<sub>3</sub>H<sub>6</sub> on Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>.

Then, to ascertain behaviours of surface adsorbed species on the oxidation of C<sub>3</sub>H<sub>6</sub> using the surface lattice oxygen, we observed DRIFT spectra for Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> and Pd/Ba/LaAlO<sub>3</sub> using the following procedure. First, 500 ppm C<sub>3</sub>H<sub>6</sub> diluted by Ar flow was applied for 15 min at 523 K after pre-treatment as the same to activity test. Then, 2000 ppm O<sub>2</sub> flowed for 15 min sequentially. This procedure was one operation; it was conducted twice. Results are shown in Fig. 6 (first operation) and S13† (second operation). In spectra for Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>, absorption bands were observed at 1300, 1598, 1717 and 1760 cm<sup>-1</sup>. These bands were assigned respectively to carbonate (1300 and 1598 cm<sup>-1</sup>)<sup>35</sup> and a C=O group of aldehyde or ketone species (1717 and 1760 cm<sup>-1</sup>).<sup>32,46,47</sup> The oxygen source was only lattice oxygen of a support material in this experimental condition. Therefore, it is considered that C<sub>3</sub>H<sub>6</sub> was oxidized by the surface lattice oxygen of La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> to form CO<sub>2</sub> and oxygenated species having C=O group. Furthermore, an increase in the intensity of bands for carbonate and

**Fig. 6** DRIFT spectra of Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> and Pd/Ba/LaAlO<sub>3</sub> during transient test (switching from C<sub>3</sub>H<sub>6</sub> to O<sub>2</sub> flow).

a decrease of that for C=O group were observed on Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> simultaneously by introducing O<sub>2</sub> sequentially. These behaviours of the bands indicate the oxidation of oxygenated species and CO<sub>2</sub> formation. Fig. S13† portrays spectra measured using the same procedure after introduction of O<sub>2</sub> in the first operation. Even in the second operation, the same bands and behaviours as in the first operation were observed on Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>. Therefore, it is deduced that the release and restoration of lattice oxygen occur on the surface of Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> at 523 K. These results agree well with those for the transient test and XPS measurements. On Pd/Ba/LaAlO<sub>3</sub>, when C<sub>3</sub>H<sub>6</sub> was introduced after pre-treatment, bands with very weak intensity were observed at 1341 cm<sup>-1</sup> and 1540 cm<sup>-1</sup>. These bands were assigned to carbonate species.<sup>33–38</sup> The different wavenumbers of carbonate species between the surface of La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> and Ba/LaAlO<sub>3</sub> derive from different adsorption states of carbonate. In subsequent steps of this DRIFTS measurement, spectra only slightly changed on Pd/Ba/LaAlO<sub>3</sub> until the end of the second operation (spectra (f)–(h) and Fig. S13†). Therefore, from transient tests, XPS and DRIFTS measurements, we inferred that Pd/Ba/LaAlO<sub>3</sub> has a slight amount of reactive lattice oxygen species on its surface and that these oxygen species do not contribute to the reaction steadily at low temperatures such as 523 K because the mobility of surface lattice oxygen is very low on Pd/Ba/LaAlO<sub>3</sub>.

Subsequently, we took another DRIFTS measurement to elucidate whether the adsorbed species is an intermediate species for NO reduction or not. This test was conducted using the same procedure by flowing 1000 ppm NO instead of O<sub>2</sub> in the second operation. Additionally, the atmosphere for this test contained 7 vol% H<sub>2</sub>O. Fig. 7(A) shows that the same oxygenated species was also formed in a wet atmosphere. Fig. 7(B) presents spectra obtained when NO was introduced to IR cell after C<sub>3</sub>H<sub>6</sub> flow. During the introduction of NO, the absorption bands for oxygenated species disappeared. The band intensity for carbonate species increased. In addition, new bands were observed at 1230, 1542 and 2163 cm<sup>-1</sup>. The assignments for these bands were, respectively, nitrite,<sup>34,36</sup> nitrate<sup>32–37</sup> and isocyanate (–NCO) species.<sup>32–35,37,38</sup> The formation of isocyanate species indicates that introduced NO reacts with the oxygenated species. Therefore, results clarified that the oxygenated species formed by the surface lattice oxygen is the intermediate species for NO reduction.

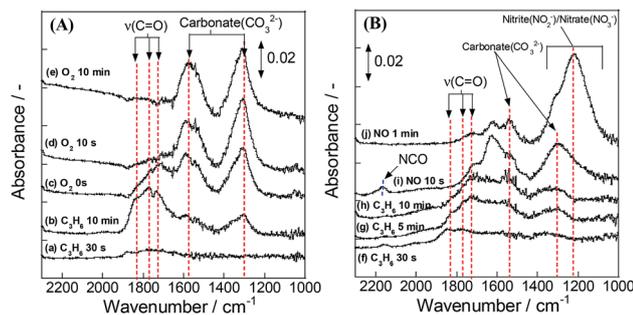

Fig. 7 DRIFT spectra of Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> during transient test in humid atmosphere: (A) first operation – switching from C<sub>3</sub>H<sub>6</sub> to O<sub>2</sub> flow; (B) second operation – switching from C<sub>3</sub>H<sub>6</sub> to NO flow.

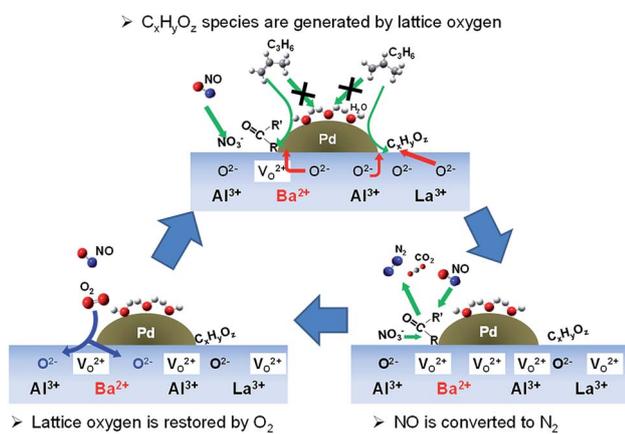

Fig. 8 Presumed reaction scheme for NO reduction on Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>.

Fig. 8 portrays the presumed reaction scheme on Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> under this slightly lean condition. NO adsorbed as NO<sub>2</sub><sup>-</sup>/NO<sub>3</sub><sup>-</sup> on La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>. At the same time, the surface lattice oxygen oxidized C<sub>3</sub>H<sub>6</sub> *via* the interface of Pd particles and La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> to form C<sub>x</sub>H<sub>y</sub>O<sub>z</sub> species. Finally, NO<sub>2</sub><sup>-</sup>/NO<sub>3</sub><sup>-</sup> and C<sub>x</sub>H<sub>y</sub>O<sub>z</sub> species react to form R-NCO as intermediate species. Isocyanate species react with NO or NO<sub>2</sub><sup>-</sup>/NO<sub>3</sub><sup>-</sup> to convert to N<sub>2</sub>, CO<sub>2</sub> and H<sub>2</sub>O.

## 4. Conclusions

We conducted reduction of NO by C<sub>3</sub>H<sub>6</sub> under slightly lean conditions with the coexistence of steam. Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> catalyst showed higher catalytic activity than Pd/LaAlO<sub>3</sub>, Pd/Ba/LaAlO<sub>3</sub> or Pd/Al<sub>2</sub>O<sub>3</sub>, especially at low temperatures (573 K or lower). For the steady-state surface reaction, NO<sub>2</sub><sup>-</sup>/NO<sub>3</sub><sup>-</sup> and oxygenated hydrocarbon species are active surface species on Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> catalyst. The cycle of release and restoration of the surface lattice oxygen was confirmed for Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub> by transient tests and XPS measurements. The lattice oxygen reacts with C<sub>3</sub>H<sub>6</sub> to oxygenated hydrocarbons very rapidly on Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>. The surface lattice oxygen contributes to the formation of intermediates and accelerates

NO reduction on Pd/La<sub>0.9</sub>Ba<sub>0.1</sub>AlO<sub>3-δ</sub>, even in humid conditions at low temperatures.
