# One-pot construction of diverse and functionalized isochromenoquinolinediones by Rh(III)-catalyzed annulation of unprotected arylamides with 3-diazoquinolinediones and their application for fluorescence sensor†

Rajeev Shrestha, (10) ‡ Hari Datta Khanal (10) ‡ and Yong Rok Lee (10) \*

A facile and efficient Rh(III)-catalyzed annulation of arylamides with 3-diazoquinolinediones for the construction of diverse and highly functionalized isochromenoquinolinediones is described. Furthermore, the methodology is applicable for delivering various relevant molecules such as pyridopyranoquinolindiones, thienopyranoquinolinones, and indolopyranoquinolinone. The reaction proceeds *via* cascade C–H activation, carbene insertion, and intramolecular lactonization. The reaction exhibits high atom economy, good functional group tolerance, and high regioselectivity. The synthesized compound can also behave as a potent fluorescence sensor for Fe<sup>3+</sup> ion.

## Introduction

Molecules bearing isochromenones or quinolinones are widely found in bioactive natural products, synthetic molecules, and pharmaceuticals.<sup>1,2</sup> They are also used as valuable building blocks for the synthesis of medicines and functional materials.<sup>3,4</sup> Among them, isochromenones containing a six-membered lactone ring possess potent biological functions such as anticancer, antimicrobial, anti-inflammatory, anticoagulant, and anti-HIV activities (Fig. 1A).<sup>5</sup> The nitrogencontaining heterocycles, quinolinones also have a broad range of biological properties including anticancer, antibiotic, antiviral, antibacterial, and antihypertensive activities (Fig. 1B).<sup>6</sup>

Owing to their importance and usefulness, various approaches for the synthesis of isochromenones or quinolinones have been developed. The typical methods for the preparation of isochromenones include nickel-catalyzed decarbonylative addition of anhydrides to alkynes,  $^7$  Rh(III)-catalyzed reaction of phosphonium ylides or benzamides with diazocarbonyl compounds,  $^8$  N-heterocyclic carbene/Lewis acid-catalyzed dimerization of 2-formylcinnamates,  $^9$  and Ru(II)-catalyzed electrooxidative [4 + 2] reaction of benzyl alcohols with alkynes.  $^{10}$  The representative strategies for the synthesis of

quinolinones include Rh-catalyzed C-H bond activation of anilines with CO and alkynes,11 Rh-catalyzed decarbonylative coupling of isatins with alkynes,12 Ru-catalyzed cyclization of anilides with propiolates or acrylates,13 Pd-catalyzed cascade reaction of anilines with acrylates,14 direct oxidation C-H amidation of amides.15 In addition, Rh(III)-catalyzed annulation of benzamides with diazo compounds for isoquinolinones was reported (Scheme 1a).16 Although a number of methods for the synthesis of isochromenones and quinolinones or isoquinolinones have been demonstrated, the direct construction of heterocycles bearing both isochromenones and quinolin-2ones are only reported sporadically.17 Recently, the reported Pd(II)-catalyzed carbonylation of alkynes is one such example (Scheme 1b).17 However, there is no example for the direct construction of highly functionalized

isochromenoquinolinediones by Rh(III)-catalyzed annulation of unprotected arylamides with 3-diazoquinolinediones.

As a part of our ongoing studies on the development of new synthetic methodologies for the construction of heterocycles utilizing diazo compounds, 18 this paper describes an efficient Rh(III)-catalyzed annulation of unprotected arylamides, isonicotinamide, thiophene-2-carboxamide, and indole-3-carboxamide with various 3-diazoquinoline-2,4-diones for the construction of diverse and functionalized heterocycles bearing isochromenones and quinolinones (Scheme 1c).

## Results and discussion

Our investigation commenced with the reaction of primary benzamide (1a) with 3-diazo-1-methylquinoline-2,4-dione (2a) in the presence of different catalysts, additives, and solvents (Table 1). The initial reaction with 2.5 mol% [RuCl<sub>2</sub>(*p*-cymene)]<sub>2</sub> and 20 mol% Cu(OAc)2 under reflux in 1,2-dichloroethane for 12 h provided the N-H insertion product 3a' (48%), along with a trace amount of 3a (entry 1). However, with 2.5 mol% of [RhCp\*Cl<sub>2</sub>]<sub>2</sub> and 20 mol% Cu(OAc)<sub>2</sub>, 3a was isolated in 64% yield as the sole product (entry 2). Importantly, [RhCp\*Cl<sub>2</sub>]<sub>2</sub> showed superior catalytic activity than [RuCl<sub>2</sub>(p-cymene)]<sub>2</sub> for the synthesis of 3a. To our delight, an increase in the amount of Cu(OAc)<sub>2</sub> to 100 mol% improved the yield of 3a to 72% (entry 3). Encouraged by this result, we screened other additives such as CsOAc, AgNO<sub>3</sub>, AgSbF<sub>6</sub>, Ag<sub>2</sub>CO<sub>3</sub>, and AgOAc for this reaction, along with 2.5 mol% [RhCp\*Cl<sub>2</sub>]<sub>2</sub> (entries 4-8). Among these, AgOAc was found to be the best additive for this transformation. Importantly, increasing the amount of AgOAc to 200 mol% not

only reduced the reaction time to 8 h, but also increased the yield of 3a to 84% (entry 9). However, decreasing the loading of AgOAc to 20 mol% decreased the yield of 3a to 52% (entry 10). In addition, decreasing the loading of [RhCp\*Cl<sub>2</sub>]<sub>2</sub> to 1.0 mol% in the presence of 200 mol% AgOAc provided 3a in 70% yield (entry 11). However, decreasing the reaction temperature to room temperature did not afford any product (entry 12). On the other hand, 3a was not obtained in the absence of AgOAc or [RhCp\*Cl<sub>2</sub>]<sub>2</sub> (entries 13-14). Further reactions using other nonpolar or polar solvents such as toluene, 2,2,2-trifluoroethanol (TFE), acetonitrile, and ethanol provided 3a in lower yields (45-68%) (entries 15-18). The structure of 3a was identified by the analysis of its spectral data. The <sup>1</sup>H NMR spectrum of 3a revealed the characteristic N-methyl peak at  $\delta$  3.80 ppm and 8 aromatic proton peaks at  $\delta$  9.60, 8.40, 8.34, 7.86, 7.67, 7.89, 7.42, and 7.35 ppm. The <sup>13</sup>C NMR spectrum of 3a exhibited peaks due to the carbonyl carbon of a conjugated lactone moiety at  $\delta$  160.7 ppm and a conjugated amide carbonyl carbon at  $\delta$  160.2 ppm. The structure of 3a was further confirmed by single-crystal X-ray crystallographic analysis of the structurally related compound 3i (Fig. 2).

With the optimized conditions in hand, we further explored the generality of the reactions by employing diversely substituted 3-diazoquinoline-2,4-diones **2b–2o** (Table 2). The reactions of **1a** with *N*-substituted 3-diazoquinoline-2,4-diones **2b–2h** bearing *N*-chloropropyl, *N*-but-3-en-1-yl, *N*-benzyl, *N*-allyl, *N*-prenyl, *N*-cinnamyl, and *N*-trans,trans-farnesyl groups were successfully carried out to produce the desired products **3b–3h** in 62–82% yields. In addition, reactions of other 3-diazoquinolindiones **2i–2o** bearing various substituents on the

<sup>&</sup>lt;sup>a</sup> Reaction conditions: 1a (0.5 mmol), 2a (0.5 mmol) in solvent (5 mL) under N<sub>2</sub>. <sup>b</sup> Isolated yields after column chromatography.

benzene ring were successful. Treatment of **1a** with 3-diazo-*N*-methylquinolindione compounds **2i–2k** bearing electron-donating groups such as 6-Me, 6-i-Pr, and 7-OMe provided the desired products **3i–3k** in 74%, 81%, and 68% yields, whereas that with diazo compounds **2l–2o** bearing electron-withdrawing groups such as 5-Cl, 6-Cl, 6-Br, and 7-Cl afforded the corresponding products **3l–3o** in 79–85% yields.

To demonstrate the versatility of this protocol, further reactions of various benzamides **1b–1m** with 3-diazo-*N*-methylquinoline-2,4-dione (**2a**) were investigated (Table 3). Treatment of **2a** with benzamides **1b–1d** bearing electrondonating groups such as 4-Me, 4-OMe, and 4-Ph on the

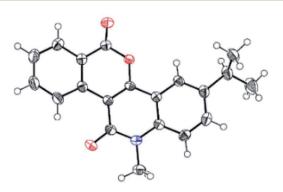

Fig. 2 X-ray structure of compound 3i (CCDC 1878962).

benzene ring provided **4a–4c** in 75%, 72%, and 78% yields, respectively, whereas the reactions with benzamides **1e–1i** bearing electron-withdrawing groups such as 4-Cl, 4-Br, 4-COMe, 4-CO<sub>2</sub>Me and 4-CN afforded **4d–4h** in 62–86% yields. However, the reaction of **1j** bearing a strong electron-withdrawing –NO<sub>2</sub> group at 4-position of the benzene ring did not afford the expected product **4i**. On the other hand, the reactions of *ortho*-substituted benzamides **1k** and **1l** with **2a** afforded the desired products **4j** and **4k** in 76% and 74% yields, respectively. In addition, when 3,4-dichlorobenzamide (**1m**) bearing two electron-withdrawing groups on the benzene ring was allowed to react with **2a**, the desired product **4l** was produced in 84% yield. In this case, other possible regioisomers were not observed.

After demonstrating the generality and versatility of this methodology, we investigated the possibility of using other arylamides 1n-1p bearing polyaromatic and heteroatomic rings with diazo compounds (Scheme 2). For example, the reaction of 2-naphthamide (1n) with 2a or 2d provided 5 and 6 in 76% and 71% yields, respectively, while that of isonicotinamide (1o) bearing a N-heteroaromatic ring with 2a or 2l afforded the desired products 7 and 8 in 48% and 58% yields, respectively. On the other hand, treatment of thiophene-2-carboxamide (1p) bearing an S-heteroaromatic ring with 2a or 2j led to the formation of the expected products 9 and 10 in 62% and 63% yields, respectively.

Table 2 Synthesis of diverse fused isochromenoguinolinediones 3b-

30 by the reaction of 1a with 2b-2o

Rh(III)

As an application of this protocol, diversely oriented polycyclic heterocycle 11 was next prepared in 62% yield employing 1-methyl-1*H*-indole-3-carboxamide (1q) with diazo compound 2a under standard reaction conditions (Scheme 3).

3o, 79%

The chemoselectivity of the reactions of different benzamides with diazo compound 2a was investigated under standard conditions (Scheme 4). Treatment of two different benzamides 1a (0.5 mmol) and 1c (0.5 mmol) with diazo compound 2a (0.5 mmol) for 8 h afforded the products 3a and 4b in 40% and 28% yields, respectively (Scheme 4, eqn (1)). On the other hand, the reaction of benzamides 1a (0.5 mmol) and 1f (0.5 mmol) afforded 3a and 4e in 37% and 42% yields,

Table 3 Synthesis of diverse isochromenoquinolinediones 4a-4l by the reaction of 1b-1m with 2a

<sup>a</sup> Reaction time = 18 h.

respectively (Scheme 4, eqn (2)). These results indicated that benzamide 1f bearing the electron-withdrawing group on the benzene ring is more chemoselective than the unsubstituted

benzamide  ${f 1a}$  and the benzamide  ${f 1c}$  bearing electron-donating groups.

To elucidate the reaction mechanism, some deuterium labelling experiments were performed (Scheme 5). The H/D exchange experiment was first carried out with 2.5 mol% Rh(III) and AgOAc (2 equivalents) of 1a (Scheme 5a). A significant deuterium exchange (65%) was observed at each of the two *ortho* positions of the benzamide to afford the product 1a'. This result suggested that the rhodation–proto(deuterio)derhodation process is reversible at the *ortho* positions. A kinetic isotope effect (KIE) experiment was next carried out (Scheme 5b).  $^{19b}$  A significant primary KIE value ( $K_{\rm H}/K_{\rm D}=3.5$ ) was observed via  $^{1}$ H NMR analysis, which indicated that C–H bond cleavage occurs during the rate-determining step.

On the basis of the control experiments and available literature, <sup>20</sup> a plausible mechanism for the formation of **3a** is depicted in Scheme 6. Initially, an active catalyst [RhCp\*(OAc)<sub>2</sub>] is generated through anion exchange from [RhCp\*Cl<sub>2</sub>]<sub>2</sub> and AgOAc. A coordination reaction between the activated catalyst

Scheme 5 Deuterium labelling experiments.

Scheme 6 Reaction mechanism for the formation of 3a.

and **1a** gives rhodacyclic intermediate **A** *via* a concerted metalation/deprotonation pathway. Then, diazo compound **2a** reacts with intermediate **A** to form carbene intermediate **B** through the release of nitrogen. Subsequently, the migratory insertion of the carbene group into the Rh–C bond delivers the eight membered rhodacycle intermediate **C** that is protonated

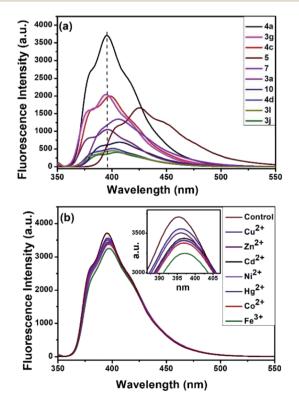

Fig. 3 (a) Fluorescence responses of different compounds (10  $\mu$ M,  $\lambda_{ex}=350$  nm). (b) Fluorescence responses of 4a in the presence of various metal cations (10  $\mu$ M,  $\lambda_{ex}=350$  nm).

Fluorescence Intensity (a.u.) Contro (a) Fe<sup>3+</sup>(900μM) 3500 100 μM 200 μM 3000 **300** μM 4a (10 uM 400 μM 2500 500 μM 600 μM 2000 700 μM 800 μM 1500 900 μM 1000 500 450 500 350 550 600 Wavelength (nm) 0.5 Y = 0.0005X + 0.0910  $R^2 = 0.9961$ 200 Fe<sup>3+</sup>  $(\mu M)$

by AcOH to yield the intermediate D, with regeneration of Rh( $\scriptstyle\rm III$ ) catalyst for the next catalytic cycle. Finally, rapid lactonization of D furnishes 3a.<sup>21</sup>

The synthesized compounds were evaluated as fluorescent sensor for sensing Fe<sup>3+</sup> ions. Currently, the use of fluorescent molecular probes emitting in the visible region has become quite significant and have attracted considerable attention in academic and industrial research.<sup>22</sup> Initially, the compound 4a (10 µM) was optimized in seven different solvents: 1,4-dioxane, dimethyl sulfoxide (DMSO), 1,2-dichloroethane (DCE), acetonitrile (ACN), dichloromethane (DCM), tetrahydrofuran (THF) and ethanol (EtOH) (Fig. S1†). Among these solvents, the compound 4a in 1,4-dioxane emitted the highest florescence maximum at 395 nm wavelength with intensity 3725 a.u. upon excitation at 350 nm. Hence, we examined the fluorescent properties of some of the synthesized compounds, *viz.* 3a, 3g, 3j, 3l, 4a, 4c, 4d, 5, 7, and 10 in 1,4-dioxane.

Interestingly, compound **4a** emitted the highest fluorescence intensity amongst all the compounds examined (Fig. 3a). Therefore, the fluorescence response of 10  $\mu$ M **4a** was recorded against various metal ions in water (Fig. 3b). Indeed, as indicated in Fig. 3b, among the different metal ions, the compound **4a** selectively sensed Fe<sup>3+</sup>. Following this, the fluorescence response of **4a** (excitation at 350 nm) was examined against various concentrations of Fe<sup>3+</sup> (100 to 900  $\mu$ M) in water (Fig. 4a). The fluorescent intensity of compound **4a** was quenched linearly by increasing Fe<sup>3+</sup> concentration with a correlation coefficient ( $R^2$ ) of 0.9961 (Fig. 4b). Hence, the

compound 4a can be utilized as a potent fluorescence sensor for  $Fe^{3+}$  ions.

## Conclusions

In conclusion, we have developed an efficient protocol for the Rh(m)-catalyzed direct annulation of unprotected arylamides, isonicotinamide, thiophene-2-carboxamide, and indole-3-carboxamide with various 3-diazoquinoline-2,4-diones to synthesize various isochromenoquinolinediones, pyridopyranoquinolinediones, thienopyranoquinolineones, and indolopyranoquinolinedione that can be widely used as a significant building block for the synthesis of bioactive natural products and pharmaceuticals. This protocol provides a rapid access to fused analogs of isochromenones as a one-pot procedure, and has several advantages such as high atom economy, high regioselectivity, and good tolerance of various functional groups with good yields. In addition, the synthesized compounds showed potent turn-off fluorescence sensing for Fe<sup>3+</sup> ion.

# Experimental

#### General information

All the reactions were carried out under nitrogen atmosphere in a 25 mL two-necked round-bottom flask with magnetic stirring. Merck silica gel plates (Art. 5554) precoated with a fluorescent indicator were used for analytical TLC analysis. Flash column chromatography was performed using silica gel 9385 (Merck). Melting points were determined using micro-cover glasses on a Fisher-Johns apparatus and are uncorrected. <sup>1</sup>H NMR and <sup>13</sup>C NMR spectra were recorded on Varian VNS (600 MHz and 150 MHz, respectively) spectrometers in CDCl<sub>3</sub>. Chemical shifts for protons were reported as parts per million in  $\delta$  scale using solvent residual peak (CHCl<sub>3</sub>: 7.24 ppm) as internal standard. Chemical shifts of <sup>13</sup>C NMR spectra were reported in ppm from the central peak of  $CDCl_3$  (77.00 ppm) on the  $\delta$  scale. Fourier transform infrared (FT-IR) spectra were recorded on a PerkinElmer FT-IR spectrometer Spectrum Two™. High-resolution mass spectra (HRMS) were obtained with a JEOL JMS-700 spectrometer at the Korea Basic Science Institute.

# General procedure for the synthesis of isochromenoquinolinone, pyridopyranoquinolinone, thienopyranoquinolinone, and indolopyranoquinolinone derivatives (3–11)

In an oven dried two-necked flask, a mixture of benzamide 1 (0.5 mmol) and 3-diazo-N-substituted quinoline-2,4-dione 2 (0.5 mmol) were dissolved in DCE (5 mL). This was then followed by addition of  $[RhCp*Cl_2]_2$  (2.5 mol%), and AgOAc (2.0 equiv.) under nitrogen atmosphere. The reaction mixture was stirred under reflux condition, and the progress of the reaction was followed by TLC analysis. After completion, the reaction mixture was cooled to room temperature. The volatiles were removed *in vacuo* and the residue was purified by silica gel column chromatography (Hex: EtOAc = 1:5) to obtain the desired products 3-11.

Fluorescence sensing of compound 4a on Fe<sup>3+</sup>. 0.50 mL of compound 4a (10  $\mu$ M) in 1,4-dioxane was taken in a 4 mL quartz cuvette as a fluorescent probe and was titrated with 0.50 mL of various metal ions (100  $\mu$ M) in water for selectivity studies. Further, the fluorescence sensitivity of compound 4a (10  $\mu$ M) was studied towards different concentrations of Fe<sup>3+</sup> in water. All the fluorescence (Hitachi-7000 F) measurements were carried out after 5 min of incubation at room temperature at 350 nm (excitation wavelength) with 5 nm of slit width, 250 V of photomultiplier tube voltage and a scan speed of 240 nm min<sup>-1</sup>.
