Validated liquid chromatography tandem mass spectrometry for simultaneous quantification of foretinib and lapatinib, and application to metabolic stability investigation

Mohammed M. Alanazi,^a Hamad M. Alkahtani,^{ID}^a Abdulrahman A. Almehezia,^{ID}^{*a} Mohamed W. Attwa,^{ID}^{*ab} Ahmed H. Bakheit^{ac} and Hany W. Darwish^{ad}

Foretinib (GSK1363089, FTB) is a multikinase inhibitor that inhibits multiple receptor tyrosine kinases, including vascular endothelial growth factor receptor-2 and mesenchymal–epithelial transition factor, with the potential for solid tumor treatment. Lapatinib (LPB) is a significant promising drug molecule that was approved by the USFDA and was utilized to develop a nontoxic and very efficient targeted therapy against breast cancer. There is an ongoing clinical trial for using of FTB and LPB combination for HER-2 positive metastatic breast cancer treatment. In the current study, liquid chromatography tandem mass spectrometry methodology was validated for simultaneous estimation of FTB and LPB with application to drug metabolic stability investigation. Chromatographic separation of FTB, LPB and masitinib (internal standard) was attained using an isocratic mobile phase running on a reversed-phase C₁₈ column. The linear dynamic range was 5–500 ng mL^{−1} with $r^2 \geq 0.9999$ in the rat liver microsomes (RLMs) matrix. The FTB and LPB metabolic stabilities in the RLMs matrix were estimated by computing two parameters, intrinsic clearance (CL_{int}: 6.33 and 5.63 mL min^{−1} kg^{−1}) and a low *in vitro* half-life ($t_{1/2}$: 23.9 and 26.9 min), which revealed the FTB and LPB high clearance by the liver from the blood. This probably revealed the low *in vivo* bioavailability that verified the low oral bioavailability previously reported and also indicated that FTB and LPB will not bioaccumulate after multiple doses. FTB metabolic rate is slightly decreased in combination with LPB, while LPB metabolic rate is greatly increased in combination with FTB. So dose recalculation must be evaluated when FTB and LPB are used in combination.

1. Introduction

Tyrosine kinase inhibitors (TKIs) are a class of drugs that inhibit the intracellular signals that drive proliferation in numerous malignant cells by unambiguously inhibiting the kinase activities of distinct intracellular pathways involved in receptor mediated growth signaling.^{1,2} Tyrosine kinases are enzymes which control γ phosphate group of ATP transfer to the tyrosine hydroxyl groups on marked proteins. They play as “on” or “off” switch in various cellular functions.³ Firm management of the tyrosine kinase activity in the cell controls important processes such as proliferation, cell cycle and cell death. In several cases, the cancer abnormal proliferation characteristics

are generated by growth factor receptor-mediated signaling. In tumor cells, the failure of the control mechanism may initiate excessive phosphorylation, and pathways retained in an activated state.^{4,5} Foretinib (FTB) and lapatinib (LPB) are TKIs.

FTB (GSK1363089, Fig. 1) is a multikinase inhibitor that inhibits multiple receptor tyrosine kinases, including vascular endothelial growth factor receptor-2 (VEGFR) and mesenchymal–epithelial transition factor (MET), with the capability for solid tumors treatment.⁶ GlaxoSmithKline launched many clinical trials for FTB in many types of cancers but in 2015, it suddenly discontinued their clinical studies for FTB. LPB (Fig. 1) is a significant promising drug molecules, approved by FDA, USA is being utilizing for the development of a nontoxic and effective targeted therapy against breast cancer.⁷ The LPB clinical effectiveness in combination with capecitabine has exhibited efficacy contrary to HER2-positive breast cancer.⁸ Besides, LPB-loaded human serum albumin nano particles have been proposed as a nontoxic therapy against HER2-positive cells.⁹ LPB belongs to a class of tyrosine kinase inhibitor, is hydrophobic in nature. LPB suppresses the abnormal activity of HER2 and EGFR by inhibiting their phosphorylation.¹⁰ Even

though, LPB has exhibited 99% bound to α -1 acid glycoprotein and human serum albumin in the blood stream.¹¹

There is an undergoing clinical trial for the use of FTB and LPB combination for the treatment of HER-2 positive metastatic breast cancer.¹² To the best of our knowledge, there has been no published analytical method for simultaneous estimation of FTB and LPB. Therefore, the purpose of the present study was to establish a validated LC-MS/MS method to quantify FTB and

LPB with application to metabolic stability estimation by computing CL_{int} *in vitro* half-life ($t_{1/2}$). These parameters could then be used for bioavailability calculations, hepatic clearance and *in vivo* $t_{1/2}$. Bioavailability is crucial as it provides an idea for tested drug metabolism; if the drug is rapidly metabolized, it will showed low bioavailability *in vivo*.¹³ Also studying the combined form metabolic stability may gave an idea about the drug–drug interaction between FTB and LPB.

Fig. 3 MRM chromatograms of (A) FTB at 1.68 min, (B) LPB at 3.5 min, and (C) MST at 0.56 min.

2. Experimental

2.1. Chemicals and reagents

All reagents and solvents were of analytical grade. Lapatinib was purchased from Med Chem Express (USA). Foretinib (FTB) and masitinib (MST) were purchased from LC Laboratories (USA). Acetonitrile (ACN), Rat liver microsomes (RLMs), and formic acid (HCOOH) were purchased from Sigma-Aldrich (USA). HPLC-grade water was obtained from the Milli-Q plus purification system (Millipore, USA).

2.2. Liquid chromatography tandem mass spectrometry methodology

An Acquity UPLC [model code (UPH) and serial number (H10UPH)] was used for chromatographic separation of RLMs incubates while Acquity TQD MS [model code (TQD) and serial number (QBB1203)] was used for mass analysis of eluted analytes peaks. MST was selected as the IS in the FTB and LPB analysis as the same method of extraction could be applied for both MST, FTB and LPB. MST is considered a TKIs and are not reported to be administered together with either FTB or LPB to the same patient at the same time. Fragmentation pattern for the analytes were explained in Scheme 1. All LC-MS/MS parameters were adjusted for efficient and fast separation for tested analytes (Table 1). Multiple reaction monitoring (MRM) detection mode was used in mass analysis of LPB, FTB and IS (Scheme 1).

2.3. Standard solutions of FTB and LPB

FTB, LPB and MST are dimethyl sulfoxide soluble. Stock of FTB and LPB were prepared (2 mg mL^{-1}) followed by ten times dilution with mobile phase to prepare FTB S1 ($200 \text{ } \mu\text{g mL}^{-1}$) and LPB S1 ($200 \text{ } \mu\text{g mL}^{-1}$), which was then further diluted ten times with mobile phase to prepare FTB S2 ($20 \text{ } \mu\text{g mL}^{-1}$) and LPB S2 ($20 \text{ } \mu\text{g mL}^{-1}$). Stock of masitinib solution ($100 \text{ } \mu\text{g mL}^{-1}$) was prepared in dimethyl sulfoxide and then further diluted fifty times with the mobile phase to prepare working MST S3 ($2 \text{ } \mu\text{g mL}^{-1}$).

2.4. Preparation of calibration standards

LPB S2 ($20 \text{ } \mu\text{g mL}^{-1}$) and FTB S2 ($20 \text{ } \mu\text{g mL}^{-1}$) were diluted with specific RLMs matrix ($40 \text{ } \mu\text{L}$ in 1 mL of phosphate buffer) to generate twelve calibration standards: 5, 10, 15, 30, 50, 75, 100, 150, 200, 300, 400, and 500 ng mL^{-1} . Three standards (15, 150, and 400 ng mL^{-1}) were selected as quality controls, namely the low quality control (LQC), medium quality control (MQC), and

high quality control (HQC), respectively. Fifty microliters of MST S3 was added to 1 mL of each calibration standard.

2.5. FTB and LPB extraction from RLMs matrix

Analytes extractions were done using ACN protein precipitation, a standard technique for metabolic stability experiments.^{14–17} ACN was used for precipitation followed by centrifugation (14 000 rpm, 12 min at 4 °C) then supernatants were filtered using syringe filters (0.22 µm pore size). Filtered samples were transferred to 1.5 mL vials. Five µL of each sample was then injected into the LC-MS/MS for analysis. Similarly, blank samples were prepared by using the stated phosphate buffer without RLMs matrix to confirm that RLMs components did not interfere with the elution time of analytes. Two calibration curve were established by plotting the peak area ratio of LPB to MST (y axis) against the nominal values (x axis) and the peak area ratio of FTB to MST (y axis) against the nominal values (x axis). A linear regression equation was used to validate the linearity of the established method. Slope, intercept, and coefficient of determination (r^2) values were computed.

2.6. Method validation

Validation parameters of the established LC-MS/MS method were described in more detail previously^{15,18,19} that included assay recovery, sensitivity, specificity, linearity, reproducibility, limit of detection (LOD) and limit of quantification (LOQ). The least squares statistical method was used to

calculate the calibration curve equations ($y = ax + b$). The linear fit was verified using the R^2 value, which was linear in the range from 2–500 ng mL⁻¹.

2.7. Metabolic stability of LPB and FTB

The metabolic stability study for LPB and FTB were done by evaluating the decrease in LPB and FTB concentrations after incubation with RLMs. One µM FTB and 1 µM LPB were incubated with RLMs (1 mg protein) in triplicate. The metabolic reaction medium was phosphate buffer (pH 7.4) that contains 3.3 mM MgCl₂. The metabolic mixture was pre-incubated at 37 °C water bath for temperature conditioning for 10 min. NADPH (1 mM) was used to initiate the metabolic reaction while 2 mL ACN was used to terminate it at specific time intervals (0, 2.5, 5, 7.5, 10, 15, 20, 40, and 50 min). The metabolic stability curve for FTB and LPB were then created. The same metabolic reaction was repeated for each analyte (LPB and FTB) in a separate experiment to assess the drug metabolic stability alone or in a mixture of both.

3. Results and discussion

3.1. HPLC-MS/MS methodology

All chromatographic parameters including the mobile phase pH, mobile phase constituents, and C₁₈ column were adjusted. The aqueous mobile phase part pH (10 mM NH₄⁺COOH) was adjusted to 4.2 with formic acid as above this

value caused unnecessary increase in elution time and peak tailing. The aqueous to organic (ACN) ratio parts of the mobile phase was optimized at 45% : 55% as ACN increase generated overlapped chromatographic peaks with bad resolution and ACN decrease resulted in higher elution times. Various types of stationary phases (*e.g.*, HILIC columns) were checked, but LPB, FTB and MST were not separated. The perfect results were attained using C₁₈ columns. The MRM mode of the mass analyzer was utilized

for LPB and FTB ions estimation to avoid potential interference from the RLM matrix constituents and increase the sensitivity of the established LC-MS/MS method (Fig. 2).

The chromatographic resolution of LPB, FTB and MST were attained in 5 min with good resolution (Fig. 3).

3.2. Method validation of the developed LC-MS/MS method

3.2.1. Specificity. MRM chromatograms reveal good resolution of the LPB, FTB and IS peaks and the absence of peaks

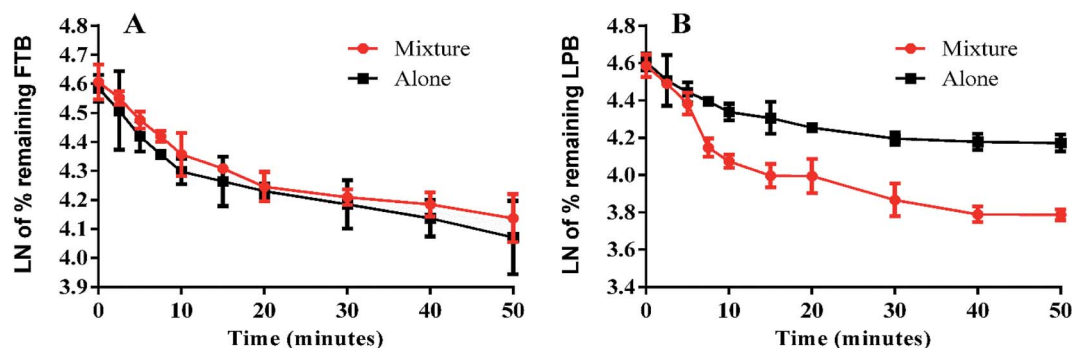

Fig. 4 Metabolic stability curve of FTB alone or in a mixture with LPB (A). Metabolic stability curve of LPB alone or in a mixture with FTB (B).

with the blank RLM matrix at their elution times, which approves the specificity of the established methodology (Fig. 3).

3.2.2. Sensitivity and linearity. The regression line linear range and correlation coefficient (r^2) for the developed chromatographic method were 5–500 ng mL⁻¹ and ≥ 0.9997 in the RLM matrix, respectively. The FTB calibration curve regression equation was $y = 0.01925x + 0.2236$. LOD and LOQ for FTB calibration curve were equal to 1.2 and 3.64 ng mL⁻¹, respectively. The LPB calibration curve regression equation was $y = 0.004721x + 0.03558$. LOD and LOQ for LPB calibration curve were equal to 2.66 and 8.051 ng mL⁻¹, respectively. The RSD values of six replicates for each standard level in the calibration curve were less than 4.93% and 3.96% (FTB and LPB) in the RLM matrix (Table 2). Back calculations of the fifteen standards of LPB in the RLM matrix (calibration and QC standards) approved the performance of the developed methodology.

3.2.3. Precision and accuracy. The intra- and inter-day accuracy and precision values are acceptable according to International Council for Harmonisation (ICH) guidelines (Table 3)^{20,21} as they are ranged from 0.36 to 3.96% and 95.12 to 101.95% for LPB, respectively, and ranged from 0.95 to 4.93% and 97.69 to 104.03% for FTB, respectively (Table 3).

3.2.4. Matrix effects and extraction recovery. Table 4 shows the recovery percentages of the quality controls when computing FTB and LPB concentration with the RLMs matrix. The FTB and LPB recoveries were $101.7 \pm 4.8\%$, $98.6 \pm 2.3\%$, respectively in the RLMs matrix. The RLMs matrix effect absence was verified by analyzing six various batches of RLMs matrixes from six different rats. These batches (named set 1) were extracted then spiked with FTB and LPB LQCs (15 ng mL⁻¹) and MST (IS). Set 2 batches were prepared in the same way utilizing the mobile phase instead of the RLMs matrix. Thus, the matrix effect was computed using the next equation:

$$\text{Matrix effect} = \text{mean peak area ratio} \frac{\text{set 1}}{\text{set 2}} \times 100$$

The tested RLM matrix that contained FTB and LPB had a matrix effect of $99.7 \pm 4.8\%$ and $97.9 \pm 3.6\%$, respectively. Accordingly, these outcomes approved that there is very low influence of the RLM matrix on FTB, LPB and MST (IS) ionization.

3.2.5. Stability. FTB and LPB stabilities of in RLMs matrix were tested under all laboratory conditions that may have been

subjected before drug analysis. FTB and LPB exhibited good stability in RLMs matrix following storage at -20°C for 30 days. Measured values were ranged from 95.45 to 107.6% for FTB and from 85.6 to 105.9% for LPB. FTB and LPB stability data is mentioned in Table 5. There was no noticeable degradation of analytes under the examined conditions.

3.3. Metabolic stability

The LPB and FTB concentrations in the RLMs matrix were computed by substitution of the peak area ratios in the linear calibration curve regression equation. Metabolic stability curves were drawn for FTB and LPB alone or in a mixture (Fig. 4). The linear portion of the established curve was used to compute *in vitro* $t_{1/2}$.²² The regression equations for this linear region were for FTB (alone: $y = -0.029x + 4.5784$ with $R^2 = 0.994$, mix: $y = -0.0251x + 4.6073$ with $R^2 = 0.998$) and for LPB (alone: $y = -0.0258x + 4.5867$ with $R^2 = 0.979$, mix: $y = -0.0546x + 4.6088$ with $R^2 = 0.969$) (Table 6).

The slope for each regression equation was substituted in the next equations:

$$\text{In vitro } t_{1/2} = \ln 2 / \text{slope}$$

$$\text{In vitro } t_{1/2} = 0.693 / \text{slope}$$

The intrinsic clearance (CL_{int}) of LPB and FTB were computed using the *in vitro* $t_{1/2}$ method¹³ as in the following equation:

$$CL_{int} = \frac{0.693}{\text{in vitro } t_{1/2}} \times \frac{\text{mL incubation}}{\text{mg microsomes}} \times \frac{45 \text{ mg microsome}}{\text{g liver}} \times \frac{20 \text{ g liver}}{\text{kg per body weight}}$$

$$CL_{int} = \frac{0.693}{\text{in vitro } t_{1/2}} \times \frac{1.45}{112.5} \times \frac{20}{0.33}$$

From these outcomes, FTB and LPB metabolic stabilities were characterized by a high CL_{int} (6.33 and 5.63 mL min⁻¹ kg⁻¹) and a low *in vitro* $t_{1/2}$ (23.9 and 26.9 min). FTB metabolic rate is slightly decreased in combination with LPB, while LPB

metabolic rate is greatly increased in combination with FTB (Table 6).

4. Conclusions

A validated LC-MS/MS methodology was developed for simultaneous estimation of FTB and LPB. The established method is highly sensitive, echo friendly (small volume of ACN), fast (run time = 5 min.), accurate, and has high recovery. The metabolic stability of FTB and LPB were characterized by a high CL_{int} (6.33 and 5.63 mL min⁻¹ kg⁻¹) and a low *in vitro* $t_{1/2}$ (23.9 and 26.9 min), which revealed a high clearance of FTB and LPB from the blood by the liver. This probably resulted in a low *in vivo* bioavailability that corroborated the low oral bioavailability previously reported and also indicated that FTB and LPB will not bioaccumulate after multiple doses. FTB metabolic rate is slightly decreased in combination with LPB, while LPB metabolic rate is greatly increased in combination with FTB. So dose recalculation should be considered when FTB and LPB are used in combination.

Authors' contributions

MAA, MWA, HAA, and HWD designed the study. MAA, HAA, and AAA supervised the practical work. AHB, MAA and MWA performed the optimization and method validation studies. MWA wrote the first version of the manuscript. All authors approved and revised the final version of the manuscript.

Abbreviations

ACN	Acetonitrile
FTB	Foretinib
LPB	Lapatinib
CL_{int}	Intrinsic clearance
CID	Collision-induced dissociation
ESI	Electrospray ionization
LC-MS/MS	Liquid chromatography tandem mass spectrometry
PI	Product ion
RLM	Rat liver microsomes
TKIs	Tyrosine kinase inhibitors
$t_{1/2}$	<i>In vitro</i> half-life
VEGFR	Vascular endothelial growth factor receptor-2
MET	Mesenchymal-epithelial transition factor
MST	Masitinib
PI	Product ion
LOD	Limit of detection
LOQ	Limit of quantification
MRM	Multiple reaction monitoring

Acknowledgements

The authors would like to extend their sincere appreciation to the Deanship of Scientific Research at the King Saud University for funding this work through the Research Group Project No. RG-1440-052.
