Utilization of 7-chloro-4-nitrobenzo-2-oxa-1,3-diazole (NBD-Cl) for spectrochemical determination of L-ornithine: a multivariate optimization-assisted approach

Hend Aly,  Ahmed S. El-Shafie  and Marwa El-Azazy *

A simple and highly sensitive univariate calibration strategy based on ultraviolet-visible (UV-Vis) absorption spectroscopy and assisted by multivariate screening and optimization was utilized for the determination of L-ornithine (L-ORN) as such and in the alimentary supplements. L-ORN, an OTC marketed amino acid, is widely used for bodybuilding and might be abused by athletes. A nucleophilic substitution reaction using 7-chloro-4-nitrobenzo-2-oxa-1,3-diazole (NBD-Cl) was the basis of the current investigation. Plackett–Burman design (PBD) and a response surface optimizer as screening and fine-tuning strategies, respectively, were instigated. Four numerical variables, reaction time (RT), temperature (Temp), pH and reagent volume (RV), and one categorical variable, the diluting solvent (DS), were considered. Absorbance of the yellow-colored adduct at 469 nm was the response studied. Pareto analysis, along with analysis of variance (ANOVA) were used to ascertain the significant variables (screening phase) and their domains (optimization phase). Response transformation and stepwise analysis were employed when necessary. Probability, cube and individual value plots were used to get an insight into the statistical impact of the variables tested. Multiple responses' optimization was performed using Derringer's function. Calibration curves were linear in the range of 5–50 $\mu\text{g mL}^{-1}$. Job's technique of continuous variation showed that the stoichiometric ratio is 2 : 1 (NBD-Cl : L-ORN). The proposed technique was successfully applied to the dietary supplements of L-ORN, inferring no interference from adjuvants and excipients. Analytical performance of this technique was validated conforming to the ICH standards.

1. Introduction

Dietary supplements are a broad term that includes a wide range of products that are administered based on a prescription or over-the-counter (OTC), due to their health impacts. World-wide sales of dietary supplements are going through a hasty growth. This dramatic progression together with the overall absence of an obligation to pass operative directions and regulations makes this market more liable to deceitful procedures, possible adulteration, and a greater incidence of safety and quality concerns. Alimentary supplements, especially those stemming from natural origins, are the most commonly used. On the one hand, because they are natural, this is a magic word that attracts customers who think that there will be no side-effects. On the other hand, since they are natural, they are available at low prices.^{1,2} The availability of sound, reliable, and sensitive techniques for the determination of these compounds *per se* and in the marketed formulations then becomes crucial. Moreover, understanding the nature (chemical and physical) of

these compounds before developing an analytical technique is an important step.

L-Ornithine (L-ORN), chemically known as (+)-(S)-2,5-diaminovaleric acid, is shown in Scheme 1. As a non-essential amino acid, it is not necessary for L-ORN to be included in humans' diets as it is already synthesized in their bodies. L-ORN is a non-proteinogenic amino acid, which is not coded naturally in the DNA, and is produced as an intermediate component of the urea cycle.^{3–5} L-ORN is one of the OTC dietary supplements that is commonly used by athletes where it is thought to have a role in increasing the mass of the muscles, as well as an ability to enhance the performance through increasing strength, the production of Human Growth Hormone (HGH) and improving fat metabolism. Moreover, L-ORN has a main role in burning up

Scheme 1 L-Ornithine monohydrochloride (L-ORN).

Department of Chemistry and Earth Science, College of Arts and Sciences, Qatar University, Doha 2713, Qatar. E-mail: marwasaid@qu.edu.qa

excess fat in the body and is used for enhancing the workability of the immune system.^{3–7}

Several techniques were reported in the literature for the determination of L-ORN. These techniques are mainly chromatography based.^{8–10} The limitations of these techniques could be summarized as univariate-based, expensive, time consuming and the requirement for well-trained staff. Spectrophotometric and spectrofluorometric analyses were also used to determine L-ORN following the formation of a colored derivative since L-ORN does not have a chromophore.¹¹ The reported study was multivariate analysis (MVA) based and employed the Hantzsch condensation reaction. The reported approach, however, could determine L-ORN in a limited concentration range.

In this study, the determination of L-ORN in its both forms (*per se* and supplements) will be performed through nucleophilic substitution reaction using 7-chloro-4-nitrobenzo-2-oxa-1,3-diazole (NBD-Cl), Scheme 2. NBD-Cl is a commonly used reagent for the quantitative determination of thiols and amines.^{12–15}

As mentioned, the literature shows that the majority of techniques reported to determine L-ORN were univariate analysis-based (UVA) implying that each variable was treated as a separate entity, an issue that does not provide any idea about the interaction between the factors. Moreover, each variable investigation would require a large number of experiments to be performed. On the contrary, multivariate analysis (MVA) which is used in this study has the ability to overcome these limitations. Furthermore, the results of MVA would provide an idea about the relationship between all the factors that might affect the reaction with a high degree of inevitability.¹⁶

Plackett–Burman design (PBD) is the screening design that is used in this study. This design is a type of fractional factorial design. The main advantage of using the PBD is that it can investigate a large number of factors with the least number of experiments, as it ignores completely the interactions between the factors. Moreover, PBD is commonly used in the pharmaceutical industry because of its economical and effectual procedures.^{17–19} Four numerical variables that are thought to have an impact on the reaction, pH, the temperature of the reaction (Temp), volume of the reagent (RV) and the reaction time (RT), plus one categorical factor, the diluting solvent (DS), will be considered.¹¹

The current study aims to develop a simple, sensitive and accurate analytical method based on UV-Vis absorption spectroscopy and 7-chloro-4-nitrobenzo-2-oxa-1,3-diazole (NBD-Cl) for determining L-ORN in its pure form and in dietary supplements

Scheme 2 7-Chloro-4-nitrobenzo-2-oxa-1,3-diazole.

with the lowest possible experimental efforts, implementing PBD as a multivariate optimization approach. To the best of our knowledge, the method we are proposing herein has not been reported before. The proposed univariate calibration strategy assisted by multivariate screening and optimization can be implemented as a quality control approach for the routine analysis of L-ORN especially in developing countries where sophisticated techniques like chromatography might not be available.

2. Experimental

2.1 Instruments and software

A UV-Vis spectrophotometer (Agilent diode-array, USA) with 10 mm matched quartz cells was used to measure the absorbance of the samples. Laboratory water bath (MLV, Salvis AG Emmenbruck, Germany) was used to heat the prepared samples to the

2.3 Reagents and standards

Stock solutions of L-ORN and NBD-Cl (1 mg mL^{-1}) in distilled water (DW) and in methanol, respectively, were freshly prepared on site. Serial dilutions were prepared in the same solvents. Several solutions of borate buffer with a pH range of 7–11 were prepared by using a mixture of $(\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O})$ and 0.1 M NaOH or 0.1 M HCl. To prepare 50 mM of $(\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O})$, 4.767 g was dissolved in 250 mL DW.²⁰

2.4 General procedure

2.4.1 Procedure for the bulk powder: screening phase of the experimental design. The variables to be investigated and their levels are shown in Table 1. A set of 16 runs was performed in two blocks, one replicate with 4 added central points. Aliquots of the drug stock solution were transferred to a series of 16 test tubes, followed by 1 mL of the buffer solution and the specified volume of the reagent according to the experimental setup shown in Table 2. Solutions were heated to the temperature needed during a specific reaction time. Solutions were cooled down, transferred to 10 mL volumetric flasks and the volume was completed to the mark with an appropriate diluting solvent as shown in Table 2. Finally, the absorbance of the yellow solutions was measured at 469 nm against a blank for each sample which is similarly prepared by omitting L-ORN.

2.4.2 Procedure of dietary supplements. Ten capsules were emptied and finely powdered in a mortar. A quantity of the powder equivalent to 100 mg of L-ORN was then dissolved in 100 mL DW. The obtained solution was then filtered, and the filtrate was transferred into a 100 mL volumetric flask and the volume was made up to the mark using the same solvent. The procedure was completed following the outlined steps under the general procedure and by implementing the optimal conditions as will be shown later.

2.4.3 Procedure of the calibration curve for the drug and dietary supplement. To construct the calibration curve of L-ORN, different volumes with final concentrations of $5\text{--}50 \text{ } \mu\text{g mL}^{-1}$ were used. Optimum conditions were followed. The same procedure was applied for the formulation solution.

2.4.4 Procedure for the standard addition method. Seven samples were prepared by adding 300 μL of the formulation to each test tube (labelled from F0–F6). Then, the solution of the drug was added in 8 different volumes starting from F1 100 μL till F6 600 μL . The buffer and the reagent were added according to the optimum conditions. The absorbance of the samples was measured against a blank following the general procedures and by applying optimal conditions.

Cube Plot (fitted means) for Y1

Fig. 7 Cube plot for the fitted means of Y1 of the L-ORN–NBD-Cl reaction product.

2.4.5 Procedure for Job's technique. Equimolar concentrations (0.0075 M) of L-ORN and NBD-Cl were prepared in order to investigate the molar ratio. The total volume was set as 5 mL. Samples were similarly prepared under the optimal conditions. Methanol was added to each volumetric flask to complete the volume to 10 mL. Finally, the absorbance was measured for each sample against its own blank.²¹

3. Results and discussion

3.1 Nucleophilic substitution reaction (SN2)

In general, the detection of amines and amino acids needs a derivatization step. The main goal of that step is to increase the detection limit at these conditions. NBD-Cl, a commonly used derivatizing agent, has an absorption maximum at 342 nm.^{12–14}

NBD-Cl generally reacts with primary and secondary amines to produce an NBD-product. The general mechanism for this reaction is shown in Scheme 3. The proposed mechanism shows that the chlorine atom in position 7 of the aromatic ring

is attacked by the amine group which acts as a nucleophile. This reaction could be performed in basic reaction media.^{12–15}

NBD-Cl derivatives are the products of nucleophilic aromatic substitution which occurs when a nucleophile displaces a good leaving group.²² L-ORN has two amine groups, which act as nucleophiles while the NBD-Cl has a chlorine atom, which is a good leaving group. Therefore, under the optimum conditions, the nucleophilic substitution reaction takes place and the response is recorded as Y1.

Absorption spectra of both L-ORN, NBD-Cl, and their reaction product were measured against reagent blanks. L-ORN does not possess a chromophore moiety and therefore absorbs in the UV region, an issue that might cause an interference from the co-formulated excipients and adjuvants in case it is determined directly without derivatization.

As shown in Fig. 1, the formed yellow coloured product has a maximum absorbance at 469 nm (red shift). It has been noticed that for some samples when the pH value is high, two peaks were obtained. The first peak might be attributed to formation of the SN2 product at 469 nm. This peak and with the

Fig. 8 Main effects plot using PBD and following response transformation.

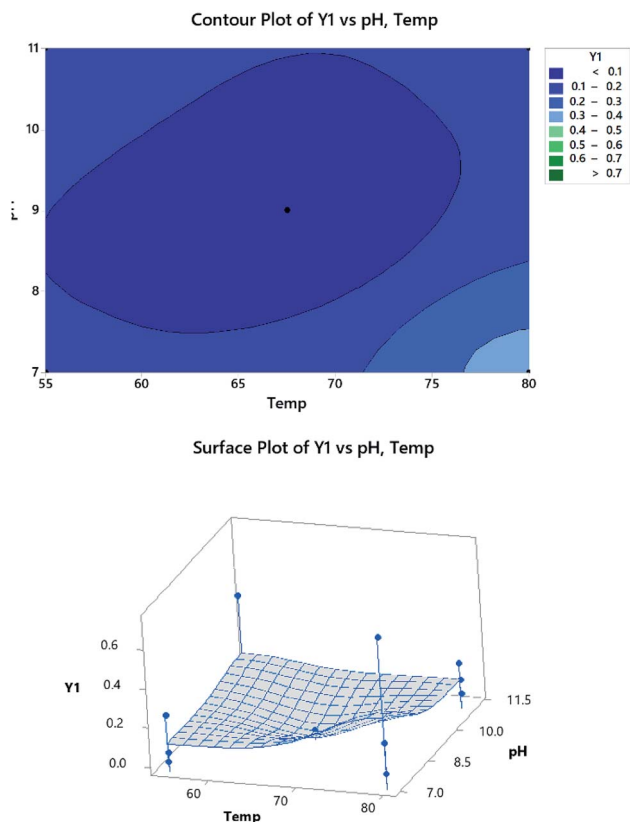

Fig. 9 Two-dimensional (2D) contour and three-dimensional (3D) surface plots.

excess of OH^- in the solution would decompose and another peak starts to form at 500 nm. The latter can be attributed to the hydrolysis of NBD-Cl at high pH and the formation of NBD-OH.²³ The latter product might cause a high background necessitating the acidification of the reaction mixture.

Table 5 Analytical parameters for the determination of L-ORN

| Parameter | Value | Parameter | Value |
|--|-----------------------|--|-----------------------|
| Wavelength, λ_{max} (nm) | 469 | Slope (b) | 0.0180 |
| Linear range, ($\mu\text{g mL}^{-1}$) ^a | 5.00–50.00 | Intercept (a) | 0.1036 |
| S_b | 2.41×10^{-4} | r^2 | 0.9991 |
| $\pm tS_b$ | 1.67×10^{-4} | LOD ($\mu\text{g mL}^{-1}$) ^b | 1.77 |
| S_a | 6.90×10^{-3} | LOQ ($\mu\text{g mL}^{-1}$) ^b | 5.38 |
| $\pm tS_a$ | 4.78×10^{-3} | Residual SS | 4.70×10^{-4} |
| $S_{y/x}$ | 9.69×10^{-3} | Regression SS | 0.5257 |

^a Regression equation: $Y = bX + a$, where Y is the absorbance, X is concentration in M , a is the intercept, b is the slope, S_b = SD of slope, $\pm tS_b$ = confidence limit for slope, S_a = SD of intercept $\pm tS_a$ = confidence limit for intercept $S_{y/x}$ = SD of the regression, SS is sum of squares. ^b LOD = limit of detection, LOQ = limit of quantification, and r^2 = coefficient of determination.

Furthermore, this product was not stable. This could be attributed to the increase in the rate of the backward reaction as the $[\text{OH}^-]$ increases, which in turn could be due to a possible competition between OH^- and the formed nucleophile, Fig. 2.

3.2 Assessments of reaction conditions

3.2.1 Assessment of the variables' impact. Predicted values of the response before and after the response transformation are shown in Table 2. Approximately all the values of the predicted responses following the transformation employing the Box-Cox transformation are close to the measured (experimental) values. The optimal value of λ (transformation factor, determined from Box-Cox transformation plots, figures are not shown) was 0 with a confidence interval (CI) of 95.0%. The regression equation is presented as:

$$\ln(Y1) = -7.26 - 0.1499\text{pH} + 0.0532\text{Temp} + 0.0421\text{RT} + 1.307\text{volume of NBD-Cl} + 0.051 \text{DS} - 2.801\text{Ct Pt} \quad (1)$$

Fig. 10 Desirability plots.

measured absorbance values. Three factors were found to be statistically significant; Temp, RT, and RV, and the latter was the most effective. All the results that were obtained from the Pareto chart were further confirmed using the analysis of variance (ANOVA), Table 3, where any factor that has a *p* value that exceeds 0.05 implies that the data do not fit the null hypothesis.^{17,18,24–28}

3.2.2 Data modeling. Following data transformation, the distribution of data was investigated employing probability plots at 95.0% CI, Fig. 4. As shown, DS was used for grouping data. The obtained *p*-values were higher than the significance level ($\alpha = 0.05$). Moreover, the data obtained followed the fitted line well. The individual value plot, Fig. 5, was used to assess data coverage and the existence of outliers. Fig. 5 shows that few outliers exist specially when using water as DS, though the data mean and median were a bit higher compared to methanol as DS.

Similarly, histograms (residual plots) were used to check the normality of the data. The histogram in Fig. 6 shows a bimodal distribution (data with 2 peaks, without categorization). A 2-sample *t*-test was further used to evaluate the influence of different DS on the absorbance of the NBD-derivative. Results showed that there is no significant difference between both solvents where *P*-value > significance level (α). Descriptive statistics are shown in Table 4. This finding further confirms that the impact of DS as shown in Fig. 3 is not statistically significant. In the same itinerary, normal probability plots are used to attest whether the data are linear or normally distributed, Fig. 4. Two parameters were used to check the linearity of the data; *p*- and Anderson–Darling (AD) values. The obtained data shows that goodness-of-fit was achieved.^{29,30}

3.2.3 Model analysis. Cube plots are an efficient way that is used to investigate the influence of the main effects on the response.³¹ As seen in Fig. 7, four cubes display all the possible blends of factorial settings, where each variable is set to two levels; lower bound and upper bound. Cubes a and b (the left and right upper panels, respectively) represent the response means when the DS is methanol, and the volume of NBD-Cl is set to its lower bound (left cube) or highest level (right cube). To assess the model predictions of fitted means, all points of the design would be tested. For example, the combination of the volume of NBD-Cl of 2 mL, pH

7, DS methanol, RT 35 min, and Temp 80 °C is associated with the highest fitted mean of Y1 (1.08867).

The main effects plot in Fig. 8 illustrates how the factors are affecting the response. Each effect is represented by a line, and the steeper the line, the greater the influence of this variable. As shown, almost all the factors' lines are not horizontal. The pH has a negative effect on the response, compared to the positive impact exerted by RT, Temp and RV.

3.2.4 Optimization phase plots. Contour plots (2D) and surface plots (3D) were used to illustrate the relationship between three variables. Two factors are plotted on the *x*-axis and *y*-axis and the response is on the *z*-axis. As seen in Fig. 9, Abs. values of 0.1–0.2 are obtained using Temp between 55–72 °C and pH 7–8. The combination between the three axes produces valleys and peaks labelled as local minima and local maxima, respectively. As seen in the lower panel in Fig. 9, the two factors that were studied are Temp with pH. A local maximum is obtained when the Temp is 67.5 °C and pH is between 8.5–10, while the local minimum is produced when Temp is 80 °C and pH is 7.

The optimization plot is shown in Fig. 10 and illustrates the optimum conditions. The purpose was to maximize the absorbance measured at 469 nm (Y1) and minimize the absorbance of the NBD-OH adduct at 500 nm (Y2). Fig. 9 shows the *d*-value (individual desirability function) for Y1 and Y2 and *D*-value (composite desirability function). The vertical red lines represent the optimal conditions for each factor. The blue dashed line represents the responses. The optimum conditions that were determined from the combination of the two responses are pH = 7, Temp = 80 °C, RT = 35 min, NBD-Cl volume = 2 mL and methanol is DS.

3.3 Stoichiometry

The results of Job's technique of continuous variation shows that the highest absorbance was achieved at a mole fraction of 0.35 (*D*) : 0.65 (NBD-Cl), implying a molar ratio of 1 (*D*) : 2 (NBD-Cl). Therefore, it can be concluded that the two amine moieties might have been involved in the reaction.

3.4 Validation

The analytical parameters are listed in Table 5. According to the ICH guidelines, the proposed method was evaluated considering the following items and as will be revealed in the following subsections.³²

3.4.1 Linearity range. Calibration curves that were obtained from the measurement of the response of the drug and the formulation against the concentration show a linear relationship in the range of 5–50 µg mL^{−1}. The regression equation is:

$$Y_{\text{pure drug}} = 0.0180X + 0.1036R^2 = 0.9991$$

3.4.2 Accuracy and precision. The % relative standard deviation, RSD% was found to be less than 5% with a confidence interval (CI) of 95.0%. The precision was evaluated three times a day for each sample (intra-days) or during three different days (inter-day). The results shown in Tables 6 and 7

indicate a high precision with low values of standard deviation (SD). Moreover, all the recovery values shown in Tables 6 and 7 are more than 95.00% with a low percentage of error, which indicates that this method is accurate.

3.4.3 Specificity. The impact of common additives and excipients on the specificity of the proposed approach was evaluated *via* applying the proposed technique on the marketed capsules either directly or after the standard addition. The results show that there was no interference from commonly formulated adjuvants, as revealed by elevated recoveries and low values of standard deviations, Table 6.

3.4.4 Limit of detection (LOD) and limit of quantification (LOQ). LOD and LOQ were calculated using the following equations:

$$\text{LOD} = 3.3 \frac{\text{SD}}{s}, \text{LOQ} = 10 \frac{\text{SD}}{s}$$

where *s* is the slope of the calibration curve and SD the standard deviation of the blank (5 measurements). Values of LOD and LOQ are shown in Table 5. This method is showing high sensitivity for the determination of L-ORN.

3.4.5 Robustness. Though the implemented factorial design, PBD, is known as a robustness test, the current approach robustness was studied by testing the impact of slight variations in the procedure variables on the measured absorbance at 469 nm. Therefore, the consequence of insignificant variations in the following factors, pH, volume of NBD-Cl, Temp, RT and DS, was tested. Changes were done as follows: pH ± 0.2 units, Temp ± 5 °C, RT ± 10 min; volume of NBD-Cl ± 0.5 mL, and DS (water and methanol). The impact of these variations was irrelevant where RSD% did not surpass 1.20%.

3.4.6 Stability of the NBD-product. The formed product was left at room temperature for periods up to 24 h. The reaction product was found to be stable for the tested time periods with a decrease in absorbance which did not exceed 2% of the measured original absorbance value, indicating the high stability of the reaction product.

4. Conclusions

L-ORN was analyzed in its pure form and in its dietary supplements using a spectrochemical approach. A nucleophilic substitution reaction was pathway taken to derivatize L-ORN using NBD-Cl. A single response (absorbance at 469 nm) was measured as a function of five variables using a multivariate-assisted strategy. PBD was used as an experimental design for the screening phase. Pareto charts and ANOVA techniques were used to determine the factors that have an impact on the response. Factorial levels were adjusted to give the maximum response. The molar ratio was determined to be (2 : 1) (reagent : drug) using Job's technique. Finally, and using ICH guidelines, the proposed method was validated.

Conflicts of interest

There are no conflicts to declare.
