# A restricted access molecularly imprinted polymer coating on metal–organic frameworks for solid-phase extraction of ofloxacin and enrofloxacin from bovine serum<sup>†</sup>

Zhian Sun, Huachun Liu, Yanqiang Zhou, Shanwen Zhao, Jianmin Li, Xiaoxiao Wang and Bolin Gong \*

A restricted access molecularly imprinted polymer (RAMIP) crosslinked with bovine serum albumin (BSA) was prepared on the surface of the mesoporous  $\text{UiO-66-NH}_2$  metal–organic framework (MOF). The surface morphology, imprinting behavior, and protein exclusion properties of  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  were investigated. The maximum adsorption capacity was  $50.55 \text{ mg g}^{-1}$  for ofloxacin, with a 99.4% protein exclusion rate. Adsorption equilibrium was reached in 9 min. Combined with RP-HPLC, a solid-phase extraction column filled with  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  was used to selectively enrich and analyze ofloxacin and enrofloxacin antibiotics from bovine serum with recoveries of 93.7–104.2% with relative standard deviations of 2.0–4.5% ( $n = 3$ ). The linear range and the limit of detection were  $0.1\text{--}100 \mu\text{g mL}^{-1}$  and  $15.6 \text{ ng mL}^{-1}$ , respectively. These results suggest that  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  is an efficient pretreatment adsorbent for biological sample analysis.

## 1. Introduction

Ofloxacin (OFL) and enrofloxacin (ENRO) are common fluoroquinolone antibiotics that are widely used because of their broad spectrum and good therapeutic effects. However, overuse has caused environmental pollution and bacterial resistance. There is thus an urgent need to develop high-performance detection technology to monitor rational applications.

There are several established methods for OFL and ENRO analysis. Complex sample pretreatment is often necessary to remove interfering components (including biological macromolecules such as proteins), and to enrich the concentration of the target. Different strategies include protein precipitation, liquid–liquid extraction, solid-phase extraction, neutral salt solutions, organic solvents, and restricted-access media (RAM). Compared with other adsorbents, RAM can extract small molecules and exclude biological macromolecules,<sup>1</sup> greatly simplifying sample pre-treatment, but it lacks target selectivity. However, molecularly imprinted polymers (MIPs) have very high selectivity for small molecules. In particular, surface imprinting overcomes the shortcomings of normal imprinting methods,<sup>2–4</sup> with a large adsorption capacity and a fast mass transfer rate. Imprinted core materials play an important role in the

adsorption properties. For example, Lv *et al.* prepared florfenicol  $\text{Fe}_3\text{O}_4@\text{RAMIP}$  (restricted access molecularly imprinted polymer) nanoparticles for the enrichment and separation of florfenicol from milk.<sup>5</sup> Xu *et al.* prepared sulfamethazine silica@RAMIP for on-line detection of sulfonamides in bovine milk.<sup>6</sup> These matrices are traditional materials, and it is necessary to find new core materials to improve the enrichment performance.

Metal–organic frameworks (MOFs) are highly crystallized porous materials of self-assembling metal ions with organic ligands.<sup>7</sup> The incorporation of MOFs in MIPs is beginning to attract great interest for separations. For example, MOF-5@MIPs for metolcarb has a higher specific surface area and a faster mass-transfer rate relative to those of bulk MIPs.<sup>8</sup> Nanocomposite MOF-5@MIPs for lipocalin greatly increased the analyte accessibility to the imprinted molecular cavities,<sup>9</sup> while  $\text{Fe}_3\text{O}_4$  nanoparticle HKUST-1@MIPs for gallic acid exhibited excellent extraction in real samples and a tunable porosity of HKUST-1.<sup>10</sup> Liu *et al.* synthesized dummy template MIL-101@MIPs to detect pyrrolidine in food samples, which exhibited fast mass-transfer rates and excellent selectivity.<sup>11</sup>  $\text{UiO-66}$  is a MOF that has good thermal stability, chemical inertness,<sup>12</sup> a wide pH range (1–14),<sup>13</sup> high pressure resistance,<sup>14</sup> and high mechanical strength.<sup>15</sup> In particular,  $\text{UiO-66-NH}_2$  is easy to modify, and is thus an ideal imprinting composite material. However, its application in RAMIPs has not been reported.

Here, newly developed imprinted RAMIPs were synthesized using OFL as a template molecule, methacrylic acid as a functional monomer, trimethylolpropane trimethacrylate as a cross-

linker, and glycidyl methacrylate as a hydrophilic monomer on the surface of  $\text{UiO-66-NH}_2$  in reversible addition–fragmentation chain transfer (RAFT) polymerization. To enhance the exclusion properties, and additional coating of cross-linked bovine serum albumin (BSA) was performed with an in-column process. The resulting RAMIPs was used to enrich OFL and ENRO from bovine serum samples.

## 2. Experimental

### 2.1. Materials and apparatus

$\text{ZrCl}_4$  ( $\geq 99.9\%$ , metals basis), glycidyl methacrylate (GMA, 97%), trimethylolpropane trimethacrylate (TRIM, GC,  $>90.0\%$ ), enrofloxacin (ENRO, 98%), chloramphenicol (CAP, 98%), sulfamerazine (SMZ, 99%), amoxicillin (AMO, 98%), methanol (HPLC,  $\geq 99.9\%$ ), acetonitrile (HPLC,  $\geq 99.9\%$ ), phosphoric acid (HPLC, 85–90%), triethylamine (HPLC,  $\geq 99.5\%$  (GC)), sodium diethyldithiocarbamate trihydrate (analytical, 99.0%), 2-chloroethyl isocyanate (97%), bovine serum albumin (BSA), glutaraldehyde (AR, 50%), sodium cyanoborohydride ( $\text{NaBH}_3\text{CN}$ , 95%), 2,2'-azobis(2-methylpropionitrile) (AIBN, 99%) were all purchased from Aladdin Industrial Corporation, and AIBN was recrystallized with absolute ethanol. Methacrylic acid (MAA, 98%) was bought from Aladdin Industrial Corporation, and was removed inhibitor in a column with neutral aluminum oxide. 2-Aminoterephthalic acid ( $\geq 98\%$ ) was obtained from Shanghai D&B Biological Science and Technology Co. Ltd. Ofloxacin (OFL, 98.5%) were bought from Tianjin Sima Technology Co., Ltd. Other reagents were analytical reagents.

The instruments that were used were a LC-20AT high performance liquid chromatography (HPLC) (Shimadzu, Japan), a SmartLab SE X-ray diffractometer (XRD) (Rigaku, Japan), a HT7700 transmission electron microscope (TEM) (Hitachi, Japan), FTIR-650 a Fourier transform infrared spectrometer (Gangdong, China), a SETARAM SETSYS16 thermogravimetric analyzer (TGA) (SETARAM, France), a ASAP 2020 HD88 surface area and porosity analyzer (Micromeritics, U.S.A), a Vario EL cube elemental analyzer (Elementar, Germany), and a UV2800S UV-visible spectrophotometer (Sunny Hengping, China).

### 2.2. Synthesis

**2.2.1. Synthesis of  $\text{UiO-66-NH}_2$ .** The synthetic protocol of  $\text{UiO-66-NH}_2@\text{RAMIP}@\text{BSA}$  composites is shown in Fig. 1.  $\text{UiO-66-NH}_2$  was synthesized according previous reports, with minor modifications.<sup>16</sup>  $\text{ZrCl}_4$  (5.0 mmol) and 2-aminoterephthalic acid (5.0 mmol) were dissolved in a 35 mL water/dimethylformamide (DMF) (5/30, v/v) solution. The mixed solution was placed in a 100 mL autoclave and heated to 120 °C for 24 h. The product was separated *via* centrifugation (5000 rpm, 15 min) and rinsed several times with DMF. The product was then solvent-exchanged for 24 h with 30 mL chloroform; this process was repeated twice. Finally, the product was dried under vacuum at 100 °C for 24 h.

**2.2.2. Preparation of RAFT (reversible addition–fragmentation chain transfer) initiator.** The  $\text{UiO-66-NH}_2$  (1.0 g) and 2-chloroethyl isocyanate (0.3 mL) were dissolved in anhydrous

10 mL of dimethylsulfoxide (DMSO) and dispersed with ultrasound for 10 min. The reaction was performed at 60 °C for 24 h. The product was then washed several times with DMSO to remove unreacted 2-chloroethyl isocyanate. The  $\text{UiO-66-NH}_2@\text{Cl}$  product was then vacuum dried for 24 h at 60 °C. Subsequently,  $\text{UiO-66-NH}_2@\text{Cl}$  (1.0 g) and sodium diethyldithiocarbamate trihydrate (1.0 g) were dispersed in 20 mL anhydrous tetrahydrofuran (THF). After purging the mixture with  $\text{N}_2$  for 20 min, the reaction was performed at 55 °C for 24 h. The product was sequentially washed with THF, methanol/water (60/40, v/v), and acetone. Finally, the  $\text{UiO-66-NH}_2@\text{SS}$  product was dried in a 60 °C vacuum oven.

**2.2.3. Preparation of  $\text{UiO-66-NH}_2@\text{RAMIP}@\text{BSA}$ .** OFL (0.25 mmol), MAA (1 mmol) and TRIM (1 mmol) were dissolved in a 25 mL methanol/acetonitrile (1/1, v/v) solution, sonicated for 5 min, and kept at 25 °C for 2 h.  $\text{UiO-66-NH}_2@\text{SS}$  (1.0 g), GMA (2 mmol), AIBN (35 mg) were then added to the mixed solution, purged with nitrogen for 20 min, and reacted for 24 h at 60 °C. The product was dried at 60 °C after being washed with methanol. The polymers were Soxhlet extracted with methanol/acetic acid (9/1, v/v) until there was no OFL in the extracting solution. The extracted  $\text{UiO-66-NH}_2@\text{MIP}$  was dispersed in 10 mL of sulfuric acid solution (0.1 mol L<sup>-1</sup>) for 10 h at 60 °C, after which the sulfuric acid was washed off the polymer surface. The resulting hydrolysate ( $\text{UiO-66-NH}_2@\text{RAMIP}$ ) was packed into the SPE column, and the vacuum of the SPE device was adjusted to keep the mixed solution [THF/acetonitrile/0.1 mol L<sup>-1</sup>  $\text{Na}_2\text{HPO}_4$ – $\text{NaH}_2\text{PO}_4$  buffer (pH 7.0), (1/9/90, v/v)] flowing through the column at a flow rate of 1 mL min<sup>-1</sup>. Meanwhile, 12.5 mL of a 5.0 mg mL<sup>-1</sup> BSA aqueous solution was added slowly. Then, 50 mL of a 5% glutaraldehyde aqueous solution was added (keeping the 2 mL min<sup>-1</sup> outflow rate). The  $\text{UiO-66-NH}_2@\text{RAMIP}$  was incubated at 25 °C for 2 h and then balanced with 2 mL min<sup>-1</sup>  $\text{NaBH}_3\text{CN}$  solution (50 mL, 0.3 mol L<sup>-1</sup>). The cross-linking reaction lasted 2 h at 25 °C, and then the column was washed with water and methanol sequentially. The final  $\text{UiO-66-NH}_2@\text{RAMIP}@\text{BSA}$  nanoparticles were vacuum dried at 25 °C.

The preparation of non-imprinted polymers ( $\text{UiO-66-NH}_2@\text{RANIP}@BSA$ ) was the same as those of the imprinted  $\text{UiO-66-NH}_2@\text{RAMIP}@BSA$ , except no template molecules were added.

### 2.3. Evaluation of protein exclusion efficiency

The protein exclusion efficiency of the  $\text{UiO-66-NH}_2@\text{RAMIP}@BSA$  was assessed by the recoveries of BSA. A SPE column filled with  $\text{UiO-66-NH}_2@\text{RAMIP}@BSA$  was activated with methanol (2 mL) and triply-distilled water (2 mL), successively. The BSA aqueous solution (1.0 mg mL<sup>-1</sup>) was flowed through the column, and the solution absorbance at 280 nm was measured. The adsorption capacity was calculated with eqn (1):

$$Q = (C_0 - C_e)V/m \quad (1)$$

where  $C_0$  (mg L<sup>-1</sup>) was the initial concentration of BSA,  $C_e$  (mg L<sup>-1</sup>) was the concentration after absorption,  $Q$  (mg g<sup>-1</sup>) was the

Fig. 1 Preparation procedures of  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$ .

adsorption capacity,  $V$  (L) was the solution volume, and  $m$  (g) was the mass of  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  or  $\text{UiO-66-NH}_2@\text{RANIP@BSA}$ .

The above procedure was the same for  $\text{UiO-66-NH}_2@\text{RANIP@BSA}$ ,  $\text{UiO-66-NH}_2@\text{RAMIP}$ ,  $\text{UiO-66-NH}_2@\text{RANIP}$ ,  $\text{UiO-66-NH}_2@\text{MIP}$ , and  $\text{UiO-66-NH}_2@\text{NIP}$ .

#### 2.4. Adsorption experiments

The saturated adsorption capacity of  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  was examined with isothermal adsorption experiments. The  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  (0.0200 g) was added to 2 mL of various OFL solutions in methanol with concentrations ranging over 100–1300 mg L<sup>-1</sup>. The adsorption process lasted for 12 h at 25 °C under oscillating conditions. The absorbance of the supernatant was measured, and the adsorption capacity was calculated from eqn (1).

The adsorption model was determined by fitting the isothermal adsorption data to Langmuir, Freundlich, and Langmuir–Freundlich models. The equations are as follows:

Langmuir equation:

$$C_e/Q_e = C_e/Q_m + 1/(K_L Q_m) \quad (2)$$

Freundlich equation:

$$\ln Q_e = (1/n) \ln C_e + \ln K_F \quad (3)$$

Langmuir–Freundlich equation:

$$Q_e = Q_m K_L^m C_e^m / (1 + K_L^m C_e^m) \quad (4)$$

$C_e$  (mg L<sup>-1</sup>) was the equilibrium concentration of OFL,  $Q_e$  (mg L<sup>-1</sup>) was the equilibrium adsorption capacity,  $Q_m$  (mg g<sup>-1</sup>) was the saturated adsorption capacity,  $K_L$  (L mg<sup>-1</sup>) is the Langmuir constant,  $K_F$  and  $n$  are constants related to adsorption capacity

Fig. 2 TEM images of (A)  $\text{UiO-66-NH}_2$ , (B)  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$ , and (C)  $\text{UiO-66-NH}_2@\text{RANIP@BSA}$ .

Fig. 3 FTIR spectra of (a)  $\text{UiO-66-NH}_2$ , (b)  $\text{UiO-66-NH}_2\text{@Cl}$ , (c)  $\text{UiO-66-NH}_2\text{@SS}$ , (d)  $\text{UiO-66-NH}_2\text{@MIP}$  and (e)  $\text{UiO-66-NH}_2\text{@RAMIP}$ .

Table 1 Elemental analysis results of  $\text{UiO-66-NH}_2\text{@RAMIP@BSA}$  and  $\text{UiO-66-NH}_2\text{@RAMIP}$

Materials	N%	C%	H%	O%
$\text{UiO-66-NH}_2\text{@RAMIP@BSA}$	6.33	41.40	5.85	24.78
$\text{UiO-66-NH}_2\text{@RAMIP}$	4.92	39.95	5.72	24.85

and adsorption strength, respectively, and  $m$  was a constant to characterize the surface inhomogeneity.

The adsorption rate was determined by kinetics experiments at 25 °C.  $\text{UiO-66-NH}_2\text{@RAMIP@BSA}$  (0.1000 g) was dispersed in an OFL/methanol solution (1200 mg L<sup>-1</sup>, 10 mL). The absorbance of the supernatant was measured every 1 min and the adsorption capacity was calculated from eqn (1).

The reaction order was determined by fitting the kinetics with the following model equations:

Pseudo first-order kinetic model:

$$\ln(Q_e - Q_t) = \ln Q_e - k_1 t \quad (5)$$

Pseudo second-order kinetic model:

$$t/Q_t = 1/(k_2 Q_e^2) + t/Q_e \quad (6)$$

$Q_e$  (mg g<sup>-1</sup>) was the equilibrium adsorption capacity,  $Q_t$  (mg g<sup>-1</sup>) was the  $t$  (min) to adsorption capacity,  $k_1$  (s<sup>-1</sup>) and  $k_2$  (g

mg<sup>-1</sup> s<sup>-1</sup>) were the pseudo first-order and pseudo second-order rate constants, respectively.

The procedures were the same for  $\text{UiO-66-NH}_2\text{@RAMIP@BSA}$ .

## 2.5. Adsorption selectivity

$\text{UiO-66-NH}_2\text{@RAMIP@BSA}$  (0.0200 g) was added to a 2 mL CAP/methanol solution (1200 mg L<sup>-1</sup>). The adsorption process lasted for 12 h at 25 °C under oscillating conditions. The adsorption capacity was calculated from eqn (1). The adsorption capacities of  $\text{UiO-66-NH}_2\text{@RAMIP@BSA}$  for ENRO, AMO, and SMZ were measured using the same procedure. The procedures were the same for  $\text{UiO-66-NH}_2\text{@RAMIP@BSA}$ .

The  $\text{UiO-66-NH}_2\text{@RAMIP@BSA}$  selectivity was characterized by the imprinting factor IF and the selectivity coefficient SC.

$$\text{IF} = Q_{\text{UiO-66-NH}_2\text{@RAMIP@BSA}}/Q_{\text{UiO-66-NH}_2\text{@RAMIP}} \quad (7)$$

where  $Q_{\text{UiO-66-NH}_2\text{@RAMIP@BSA}}$  and  $Q_{\text{UiO-66-NH}_2\text{@RAMIP}}$  (mg g<sup>-1</sup>) were the adsorption capacities of  $\text{UiO-66-NH}_2\text{@RAMIP@BSA}$  and  $\text{UiO-66-NH}_2\text{@RAMIP}$ , respectively, for the target molecules.

$$\text{SC} = Q_{\text{OFL}}/Q_{\text{CM}} \quad (8)$$

where  $Q_{\text{OFL}}$  and  $Q_{\text{CM}}$  (mg g<sup>-1</sup>) were the  $\text{UiO-66-NH}_2\text{@RAMIP@BSA}$  adsorption capacities for OFL and competing molecules (ENRO, AMO, SMZ and CAP), respectively.

## 2.6. Spiked recovery experiments and analysis of real samples

OFL and ENRO methanol/water (1/1, v/v) standard solutions (500 mg L<sup>-1</sup>) were prepared. To three 100 mL volumetric flasks were added 0.1 mL, 1.0 mL, and 10 mL of the OFL standard solution, and each was diluted with bovine serum to the calibration line. A SPE column filled with  $\text{UiO-66-NH}_2\text{@RAMIP@BSA}$  or  $\text{UiO-66-NH}_2\text{@RAMIP@BSA}$  was activated with methanol (2 mL) and triply-distilled water (2 mL), successively. Without pretreatment, the bovine serum samples (10 mL) were injected directly into the SPE column, then the column was washed with 3 mL of water. The OFL and ENRO was eluted with a 3 mL mixture of methanol/acetic acid (9/1, v/v). The eluent was

Fig. 4 (A) The specific surface area and (B) the pore size distribution (a)  $\text{UiO-66-NH}_2$  and (b)  $\text{UiO-66-NH}_2\text{@RAMIP@BSA}$ .

**Table 2** Protein exclusion rate of  $\text{UiO-66-NH}_2@\text{MIP}$ ,  $\text{UiO-66-NH}_2@\text{NIP}$ ,  $\text{UiO-66-NH}_2@\text{RAMIP}$ ,  $\text{UiO-66-NH}_2@\text{RANIP}$ ,  $\text{UiO-66-NH}_2@\text{RAMIP}@{\text{BSA}}$  and  $\text{UiO-66-NH}_2@\text{RANIP}@{\text{BSA}}$ 

Materials	Concentration of BSA (mg mL <sup>-1</sup> )	$A (\lambda = 280 \text{ nm})$		Binding ability (%)	Exclusion ability (%)
		Before SPE	After SPE		
$\text{UiO-66-NH}_2@\text{MIP}$	1	0.643	0.235	63.5	36.5
$\text{UiO-66-NH}_2@\text{NIP}$	1	0.643	0.239	62.8	37.2
$\text{UiO-66-NH}_2@\text{RAMIP}$	1	0.643	0.617	4	96.0
$\text{UiO-66-NH}_2@\text{RANIP}$	1	0.643	0.615	4.4	95.6
$\text{UiO-66-NH}_2@\text{RAMIP}@{\text{BSA}}$	1	0.643	0.639	0.6	99.4
$\text{UiO-66-NH}_2@\text{RANIP}@{\text{BSA}}$	1	0.643	0.638	0.8	99.2

dried with nitrogen and dissolved again with 0.1 mL of the mobile phase. Samples (15  $\mu\text{L}$ ) were taken for detection. The chromatographic conditions were: C18 column (250 mm  $\times$  4.6 mm, 5  $\mu\text{m}$ , Shimadzu); a mobile phase of 0.025 mol L<sup>-1</sup> phosphoric acid aqueous solution (pH adjusted to 3 with triethylamine)/acetonitrile = 85/15 (v/v); a flow rate of 1 mL min<sup>-1</sup>; a column temperature of 40 °C; and a UV detection wavelength of 286 nm.

### 3. Results and discussion

#### 3.1. Synthesis of ofloxacin-imprinted $\text{UiO-66-NH}_2@\text{RAMIP}@{\text{BSA}}$

The synthesis of  $\text{UiO-66-NH}_2@\text{RAMIP}@{\text{BSA}}$  nanoparticles is illustrated in Fig. 1. The mesoporous  $\text{UiO-66-NH}_2$  substrate had excellent thermal stability, chemical inertness, stable physical and chemical properties, and a high adsorption capacity. The MIP layer was coated on the  $\text{UiO-66-NH}_2$  surface *via* RAFT. The first step was to prepare the initiator-functionalized  $\text{UiO-66-NH}_2$  ( $\text{UiO-66-NH}_2@\text{SS}$ ). In the second step, the functional monomer MAA provided hydrogen bonding with the OFL template, TRIM was the cross-linking reagent used to form the polymer network, and GMA was used to form the first hydrophilic layer. The MIP layer easily grew from the initiator according to the RAFT mechanism. After Soxhlet extraction, the surface cavities could selectively rebind template molecules because they matched in shape, size, and chemical functional groups. After undergoing hydrolysis, the  $\text{UiO-66-NH}_2@\text{RAMIP}$  surface was covered with hydroxyl groups to prevent irreversible protein

adsorption. Theoretically, the proportions of template molecule, functional monomer, crosslinking agent, and hydrophilic monomer could affect the adsorption performance. Hence, the ratios of OFL to MAA, MAA to TRIM, and TRIM to GMA were all optimized. The experimental range was 1 : 4, between 1 : 0.6 to 1 : 1.6, and between 1 : 1.5 to 1 : 3, respectively. Finally, cross-linking BSA was immobilized on the  $\text{UiO-66-NH}_2@\text{RAMIP}$  surface to form a second hydrophilic layer to enhance the protein exclusion efficiency.

#### 3.2. Characterization of ofloxacin-imprinted $\text{UiO-66-NH}_2@\text{RAMIP}@{\text{BSA}}$

The morphologies of  $\text{UiO-66-NH}_2$ ,  $\text{UiO-66-NH}_2@\text{RAMIP}@{\text{BSA}}$ , and  $\text{UiO-66-NH}_2@\text{RANIP}@{\text{BSA}}$  were imaged with TEM. As shown in Fig. 2A,  $\text{UiO-66-NH}_2$  was an octahedral crystal with a smooth surface.  $\text{UiO-66-NH}_2@\text{RAMIP}@{\text{BSA}}$  nanoparticles were evenly encapsulated by the 21.2 nm-thick polymer, suggesting that the RAMIP layer were successfully coated on the  $\text{UiO-66-NH}_2$  surface. In addition, the thick and uniform imprinting layer could accelerate the mass-transfer rate and provide more adsorption sites. Fig. 2B and C indicates that the surface morphology of  $\text{UiO-66-NH}_2@\text{RANIP}@{\text{BSA}}$  was similar to that of  $\text{UiO-66-NH}_2@\text{RAMIP}@{\text{BSA}}$ .

The preparation of the adsorbent was also confirmed with FTIR spectra (Fig. 3) and an elemental analysis (Table 1). In Fig. 3, the broad band at 1350–1700 cm<sup>-1</sup> could be assigned to the  $\text{COO}^-$  symmetrical and asymmetrical stretching vibration of  $\text{UiO-66-NH}_2$  in the five spectra (Fig. 3a–e). The 3353 cm<sup>-1</sup> and 3450 cm<sup>-1</sup> peaks in Fig. 3a were attributed to a N–H vibration

Fig. 5 Results of (A) absorption capacity and (B) absorption kinetics.

from  $\text{UiO-66-NH}_2$ . Comparing the a and b spectra, the absorption peaks of  $\text{C-Cl}$  ( $735 \text{ cm}^{-1}$ ),  $\text{C=O}$  ( $1693 \text{ cm}^{-1}$ , redshifted by two associated  $\text{N-H}$  bonds),  $\text{CH}_2$  ( $2880 \text{ cm}^{-1}$ ) and  $\text{CH}_3$  ( $2931 \text{ cm}^{-1}$ ) appeared in curve Fig. 3b, which verified that 2-chloroethyl isocyanate was grafted on the  $\text{UiO-66-NH}_2$  surface. In Fig. 3c,  $\text{C-S}$  and  $\text{C=S}$  peaks appeared at  $615 \text{ cm}^{-1}$  and  $1060 \text{ cm}^{-1}$ , respectively, verifying the grafting of sodium diethyldithiocarbamate trihydrate. In Fig. 3d, the  $\text{C=O}$  overtone peak from esters occurred at  $3440 \text{ cm}^{-1}$ . The symmetrical and asymmetrical  $\text{C-H}$  stretching vibration ( $2965 \text{ cm}^{-1}$ ) and the ester carbonyl group stretching vibration ( $1731 \text{ cm}^{-1}$ ) were significantly enhanced. Two strong  $\text{C-O-C}$  peaks appeared between  $1100$ – $1300 \text{ cm}^{-1}$ , and the epoxy group absorption peak appeared at  $908 \text{ cm}^{-1}$ . All of these data indicated that MAA, TRIM, and GMA were grafted onto the surface of  $\text{UiO-66-NH}_2@\text{SS}$ . In Fig. 3e, the  $\text{C-O}$  stretching vibration and the  $\text{O-H}$  deformation vibration occurred at  $1050 \text{ cm}^{-1}$  and  $1334 \text{ cm}^{-1}$ , respectively. Thus, the peak at  $3400 \text{ cm}^{-1}$  was an  $\text{OH}$  band, which verified the hydrolysis of the epoxy group.

The amount of BSA bonding could be determined by the elemental analysis (Table 1). The N, C, and H content in  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  increased, which indicated that BSA had been cross-linked on the  $\text{UiO-66-NH}_2@\text{RAMIP}$  surface.

The specific surface areas of  $\text{UiO-66-NH}_2$  and  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  were determined by BET (Fig. 4A) to be  $332.6 \text{ m}^2 \text{ g}^{-1}$  and  $210.4 \text{ m}^2 \text{ g}^{-1}$ , respectively. These were much higher than other MIPs,<sup>17,18</sup> which was the basis for the increase of adsorption capacity. Furthermore, as shown in Fig. 4B,  $\text{UiO-66-NH}_2$  and  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  were mostly mesoporous. Mesoporous MOFs can greatly increase the pore utilization rate and accelerate mass transfer relative to microporous MOFs.<sup>8-11</sup>

XRD (Fig. S1 in the ESI†) and thermogravimetric analysis (Fig. S2†) revealed that  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  had good chemical and thermal stability, and could meet the needs of practical applications.

### 3.3. Protein exclusion efficiency of $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$

Protein adsorption on the different materials was estimated by injecting a  $1 \text{ mg mL}^{-1}$  BSA solution on SPE columns packed with  $\text{UiO-66-NH}_2@\text{MIP}$ ,  $\text{UiO-66-NH}_2@\text{RAMIP}$ ,  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  and the corresponding non-imprinted particles. The recovery of BSA from the columns was used to evaluate the various protein exclusion efficiencies. Table 2 shows that the BSA recoveries of  $\text{UiO-66-NH}_2@\text{MIP}$  and  $\text{UiO-66-NH}_2@\text{NIP}$  without grafting poly (GMA) and introducing the BSA layer were just 36.5% and 37.2%, respectively, while that of  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  and  $\text{UiO-66-NH}_2@\text{RANIP@BSA}$  were 99.4% and 99.2%, respectively. The latter were much higher than those of  $\text{UiO-66-NH}_2@\text{RAMIP}$  (96.0%) and  $\text{UiO-66-NH}_2@\text{RANIP}$  (95.6%). Hence, further cross-linking of BSA on the  $\text{UiO-66-NH}_2@\text{RAMIP}$  surface could increase the hydrophilicity of the RAMIP materials. The formation of the hydrophilic bilayer by grafting poly (GMA) chains, and after introducing BSA on the  $\text{UiO-66-NH}_2$  surface, resulted in excellent protein exclusion

Fig. 6 Adsorption capacity of OFL, ENRO, CAP, SMZ and AMO on (a)  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  and (b)  $\text{UiO-66-NH}_2@\text{RANIP@BSA}$ .

efficiency. Therefore,  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  was the most suitable SPE material for pre-treating biological samples.

### 3.4. Absorption capacity and kinetics

The adsorption capacities of  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  and  $\text{UiO-66-NH}_2@\text{RANIP@BSA}$  were initially determined with adsorption isotherms. As shown in Fig. 5A, the adsorption capacities were enhanced with increasing standard solution concentration over the range  $100$ – $1300 \text{ mg L}^{-1}$ , and reached saturation at  $50.55 \text{ mg g}^{-1}$  and  $16.40 \text{ mg g}^{-1}$ , respectively. The adsorption capacity of  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  was much larger than that of  $\text{UiO-66-NH}_2@\text{RANIP@BSA}$ . Compared with reported MIP absorbents,  $Q_{\max}$  for  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  was higher than that of absorbents using silica and polymer resin,<sup>19–27</sup> indicating that the  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  composites exhibited efficient extraction and could have wide analysis applications. The adsorption rate of  $\text{UiO-66-NH}_2$

Fig. 7 The chromatograms of (a) the blank bovine serum, (b) the elution of  $\text{UiO-66-NH}_2@\text{RAMIP@BSA}$  after treatment of spiked bovine serum and (c) the elution of  $\text{UiO-66-NH}_2@\text{RANIP@BSA}$  after treatment of spiked bovine serum.

Table 3 Recoveries of OFL and ENRO obtained from spiked bovine serum

Analytes	Materials	0.5 $\mu\text{g mL}^{-1}$		5 $\mu\text{g mL}^{-1}$		50 $\mu\text{g mL}^{-1}$	
		Recovery (%)	RSD (%)	Recovery (%)	RSD (%)	Recovery (%)	RSD (%)
OFL	UiO-66-NH <sub>2</sub> @RAMIP@BSA	93.7	3.6	94.9	4.5	104.2	2.0
	UiO-66-NH <sub>2</sub> @RANIP@BSA	31.2	4.1	33.4	3.3	36.5	2.3
ENRO	UiO-66-NH <sub>2</sub> @RAMIP@BSA	95.5	4.0	94.1	4.1	102.6	3.4
	UiO-66-NH <sub>2</sub> @RANIP@BSA	30.8	3.8	32.5	2.9	35.7	4.4

NH<sub>2</sub>@RAMIP@BSA was investigated. In Fig. 5B, adsorption equilibrium was reached in 9 min, which was much faster than that of MIPs prepared by traditional polymerization methods and other imprinting materials. This was because of the uses of mesoporous MOF substrate. Recently, a RAMIP was prepared using 2  $\mu\text{m}$  spherical silica gel and atom-transfer radical polymerization.<sup>28</sup> Although this material has some advantages in adsorption capacity and limits of detection, UiO-66-NH<sub>2</sub>@RAMIP@BSA has a better adsorption rate, protein exclusion efficiency, and recovery.

The results of the Langmuir, Freundlich, and Langmuir-Freundlich fits are shown in Table S1.<sup>†</sup> By comparing the  $R^2$  values, it could be concluded that the adsorption of OFL on UiO-66-NH<sub>2</sub>@RAMIP@BSA and UiO-66-NH<sub>2</sub>@RANIP@BSA corresponded to the Langmuir-Freundlich model. From the fitting results, the theoretical value of  $Q_m$  from that model was closer to the measured value. The  $K_L$  value of UiO-66-NH<sub>2</sub>@RAMIP@BSA was much larger than that of UiO-66-NH<sub>2</sub>@RANIP@BSA, which indicated that UiO-66-NH<sub>2</sub>@RAMIP@BSA was more attractive to OFL. At the same time, the  $m$  value of UiO-66-NH<sub>2</sub>@RANIP@BSA was close to 1, which indicated that its adsorption sites were more uniform because they all involved physical adsorption. The higher  $m$  value for UiO-66-NH<sub>2</sub>@RAMIP@BSA indicated nonuniform adsorption sites that involved both nonspecific physical adsorption and specific chemical adsorption.

The kinetics fits are shown in Table S2.<sup>†</sup> From the  $R^2$  values, it could be concluded that adsorption on UiO-66-NH<sub>2</sub>@RAMIP@BSA correlated with pseudo second-order kinetics. The fitting results showed that its adsorption rate was determined by the square of the number of unoccupied imprinted surface sites, and the mechanism was chemical adsorption, which involves electronic bonding between the adsorbent and the adsorbate. This result also confirmed the theoretical analysis of Section 3.1.

### 3.5. Adsorption selectivity of UiO-66-NH<sub>2</sub>@RAMIP@BSA

The selectivity of UiO-66-NH<sub>2</sub>@RAMIP@BSA was compared with that of UiO-66-NH<sub>2</sub>@RANIP@BSA. The three commonly used antibiotics AMO, SMZ, and CAP, and the structural analogue ENRO of OFL, were used to investigate adsorption selectivity, as shown in Fig. 6. The IF values for OFL, ENRO, AMO, SMZ, and CAP were 3.00, 3.25, 1.14, 1.50, and 1.50, and its SC were 1.26, 33.48, 15.70, and 10.87, respectively. The molecular sizes increased in the order SMZ, CAP, OFL  $\approx$  ENRO, and

AMO. Because the molecular size and structure of the analogue ENRO were the most similar to those of OFL, its adsorption capacity was higher relative to those of SMZ, AMO, and CAP. The molecular mass of CAP was similar to that of OFL, but its structure was different, so its adsorption capacity decreased greatly. The size of SMZ was smaller than that of CAP, so its adsorption capacity was lower than that of CAP. The size of AMO was the largest; therefore, it had the lowest adsorption capacity because of less physical adsorption, which led to the minimum IF. Thus, UiO-66-NH<sub>2</sub>@RAMIP@BSA had high selectivity and could recognize OFL and ENRO in the presence of other commonly used antibiotics.

### 3.6. Enrichment and separation of OFL and ENRO in bovine serum by the UiO-66-NH<sub>2</sub>@RAMIP@BSA

Under the optimized conditions, UiO-66-NH<sub>2</sub>@RAMIP@BSA was used to selectively extract OFL and ENRO from bovine serum samples *via* RP-HPLC. Chromatograms of bovine serum samples are shown in Fig. 7. None of the target compounds were detected in the bovine serum samples (curve a), while OFL and ENRO could be detected after enrichment by using UiO-66-NH<sub>2</sub>@RAMIP@BSA (curve b) and the non-imprinted materials (curve c). The method is illustrated in Table 3. Specifically, the determinations were evaluated by using bovine serum samples spiked with OFL and ENRO at concentrations of 0.5, 5, and 50  $\mu\text{g mL}^{-1}$ ; the recoveries of OFL and ENRO were 93.7–104.2%, and the RSDs were 2.0–4.5% ( $n = 3$ ). The linear range and LOD were 0.1–100  $\mu\text{g mL}^{-1}$  and 15.6  $\text{ng mL}^{-1}$ , respectively. Relative to other core materials (Table S3<sup>†</sup>), UiO-66-NH<sub>2</sub> had advantages in addition to the slightly higher LOD. In summary, the UiO-66-NH<sub>2</sub>@RAMIP@BSA could be used for highly selective enrichment and separation of OFL and ENRO in biological samples.

## 4. Conclusions

Highly hydrophilic UiO-66-NH<sub>2</sub>@RAMIP@BSA was prepared, and its protein exclusion rate was 99.4%. Its adsorption capacity was as high as 50.55  $\text{mg g}^{-1}$ , and the adsorption could reach equilibrium within 9 min. Combined with RP-HPLC, it was successfully used to separate and detect OFL and ENRO in bovine serum. The recoveries were 93.7–104.2% and the RSDs were 2.0–4.5%. The detection limit was 15.6  $\text{ng mL}^{-1}$  and the linear range was 0.1–100  $\mu\text{g mL}^{-1}$ . Compared with previous reports, the performance of this material was much better,

which greatly simplifies pretreatment steps of biological samples and improves the analysis efficiency.
