# Tumor homing peptide modified liposomes of capecitabine for improved apoptotic activity and HER2 targeted therapy in breast cancer: *in vitro* studies

Mantosh Kumar Singh,<sup>a</sup> Sai Kiran S. S. Pindiprolu,<sup>b</sup> Bharat Kumar Reddy Sanapalli,<sup>a</sup> Vidyasrilekha Yele<sup>c</sup> and G. N. K. Ganesh<sup>\*a</sup>

In the present study, we have formulated a liposomal formulation of cytotoxic agent capecitabine (CAP) to overcome its bioavailability issues. Then we have surface modified CAP loaded liposomes (CAP-LPs) with a tumour homing peptide (THP-CAP-LPs) to achieve site specific delivery to breast cancer cells. We found a significant cellular internalization of THP-CAP-LPs when compared to unmodified CAP-LPs. The cytotoxic effect of CAP was also significantly improved with THP-CAP-LPs by downregulating anti-apoptotic proteins and upregulating pro-apoptotic proteins as observed by Western blot analysis. THP-CAP-LPs mediated delivery of CAP can be, therefore, a promising approach for improving antitumor activity and reducing off-target effects.

## Introduction

Based on the expression of estrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor receptor-2 (HER2) receptor, breast cancers can be classified into estrogen receptor positive (luminal subtype), HER2, PR and triple-negative breast cancer (TNBC), which lacks ER, PR and HER2 expression.<sup>1–3</sup> The HER2 receptor has an intracellular tyrosine kinase domain and an extracellular ligand binding domain, and is involved in important stages of growth and cell differentiation. As a key gene of cell survival, HER2 overexpression can lead to malignant progression, which is associated with unfavourable prognosis of breast, ovary, gastric, prostate cancers, among others. HER2 overexpression is present in approximately 25% of all breast cancers and usually is associated with more aggressive disease and endocrine therapy resistance. Studies showed that the inhibition of HER2 expression induced significant apoptosis in breast cancer cells and therefore HER2 became a target.

5-Fluoro Uracil (5-FU) is a commonly used drug for treatment of HER2 positive breast cancer. Capecitabine (CAP) is a prodrug of 5FU and effective in treatment of breast cancer. However, off target effects and poor bioavailability are the major limitations for CAP based therapy. Drug delivery using liposomes is a widely

recognized approach for minimizing off-target effects and to increase the concentration of drug at the tumour site. Liposomes with appropriate stealth properties, avoid rapid clearance and accumulate at the site of tumour by enhanced permeation–retention (EPR) effect.<sup>4,5</sup> However, compelling body of evidence suggest that this accumulation does not provide specific targeting and sufficient intracellular delivery.<sup>6</sup> The concept of active targeting approach by conjugating an appropriate peptide for specific tumour marker on the surface of nanocarriers is an attractive strategy for selective delivery of drugs to tumours.<sup>7</sup> In the present study we, therefore, propose HER2+ breast cancer cell specific binding or tumour homing peptide (THP) (WNLWPWYYSVSPTC) conjugated CAP liposomes (THP-CAP-LPs) for site specific targeting and improved cell uptake of CAP in breast cancer cells.

## Results & discuss

### Optimization of THP-CAP-LPs

The optimization was done based on the responses observed for all 20 formulations (Table 2). The effects of pre-determined factors on particle size (PS) and entrapment efficiency (EE) was observed using perturbation plots and response surface plots (Fig. 1). The model was validated by applying analysis of variance (ANOVA)<sup>20</sup> (Tables 3 and 4). The optimized formulation was selected using desirability criterion of PS and EE. It was predicted according to the design that 445.44 mg of cholesterol acrylate, 43.05 mg of CAP and 5.01 min of sonication will give PS of 114.036 nm and EE of 80.87% (Fig. 2). Based on the predicted composition of lipid surfactant and co-surfactant a new batch of

THP-CAP-LPs was prepared. The actual values are in close agreement with predicted values regression formula generated for the design in terms of coded factors is

$$PS = 104.29 - 5.23A + 6.99B - 5.09C - 1.76AB - 3.85AC + 4.84BC + 38.68A^2 + 31.61B^2 + 23.75C^2$$

$$EE = 82.67 + 0.72A - 0.62B - 0.018C - 3.54AB + 0.39AC + 0.89BC - 6.09A^2 - 5.29B^2 - 5.30C^2$$

where, PS and EE are particle size and entrapment efficiency respectively.

### Characterization of CAP-LPs and THP-CAP-LPs

The result obtained by FTIR representing no compatibility issues between the drug and excipients used (Fig. 4a). The developed formulation THP-CAP-LPs was confirmed by using high resolution mass spectrometry (HRMS). The theoretical molecular weight of the formulation was found to be 2316.5 and observed molecular weight of the given formulation was found to be 2316.7  $[M + H]^+$  (Fig. 3a and b). By dynamic light scattering, it was observed that particle size of THP-CAP-LPs is  $148.18 \pm 1.73$  nm. When compared to CAP-LPs ( $116.20 \pm 1.54$  nm), the particle size of THP-CAP-LPs was high which may be due to the surface modification of peptide. Zeta potential of CAP-LPs and THP-CAP-LPs was  $-7.8$  mV and  $3.7$  mV respectively (Fig. 4b and c). The zeta potential shift may be due to the Michael group ( $\alpha$ - $\beta$  unsaturated group produced when treating with acryloyl chloride) of cholesterol conjugation with THP by a covalent bond formation. This suggests the proper conjugation of the amine group of THP. SEM and TEM studies reported that THP-CAP-LPs was mono-dispersed and spherical shaped (Fig. 4d and e). The entrapment efficiency of THP-CAP-LPs and CAP-LPs was found to be  $69.76 \pm 0.11\%$  and  $79.23 \pm 0.55\%$  respectively. The drug loading of THP-CAP-LPs and CAP-LPs was found to be  $34.72 \pm 0.11\%$  and  $29.75 \pm 0.44\%$ .

### *In vitro* release of CAP from CAP-LPs and THP-CAP-LPs

There was no burst release of CAP observed with THP-CAP-LPs and CAP-LPs (Fig. 5). Lipids enhance the rigidity of the encapsulation layers. Surface modification of the lipid can, therefore, alter the flexibility of the lipid layer and delay the rate of drug release. In our study, there is sustained release of drug in THP-CAP-LPs when compared to CAP-LPs this may be due to surface modification. Abnormal glycolytic rate, high lactic acid generation and inappropriate drainage by convective transport, H<sup>+</sup> ions stack up can be seen in the tumor tissue. So, there will be acidic pH at tumor site.<sup>21</sup> To mimic the pH variation between cellular exterior (pH 7.4) and intracellular lysosome (pH 4.5), drug release was carried out at different pH environment. CAP is a weak acid and alkaline in nature is due to the pair of sulfide groups and it shows higher solubility at lower pH. Thereby, the encapsulated CAP in the liposomes has tendency to enter into the release medium of lower pH.

### Cellular uptake and cytotoxic activity of CAP, CAP-LPs and THP-CAP-LPs

Cellular uptake of the THP-CAP-LPs and CAP-LPs was evaluated in MDA-MB453 cells. For cellular uptake imaging studies, the CAP was replaced with Rhodamine 6G in CAP-LPs and THP-CAP-LPs to form Rh-LPs and THP-Rh-LPs (Fig. 6). The *in vitro* cytotoxic activity of CAP, THP-CAP-LPs and CAP-LPs were evaluated by the SRB assay in MDA-MB453 cell line, the cell viability is shown in (Fig. 6). Blank LPs didn't exhibit significant cytotoxicity in MDA-MB 453 cells which confirm the safety of the LPs as carriers. MDA-MB453 cells treated with CAP-LPs and THP-CAP-LPs exhibited cytotoxicity at various concentrations (1.562, 3.125, 6.25, 12.5, 25, 50, 100 μM). It is evident that CAP, CAP-LPs and THP-CAP-LPs exhibited dose-dependent cytotoxic action. CAP naive drug exhibited lower cytotoxic action when compared to CAP-LPs and THP-CAP-LPs which may be due to the efflux of the diffused drug in the cytoplasm by P-

glycoprotein (P-gp) pumps. CAP-LPs and THP-CAP-LPs can inhibit P-gp mediated drug efflux (Fig. 7).<sup>8-11,22-24</sup>

### THP-CAP-LPs augmented the expression of proapoptotic proteins and inhibited antiapoptotic protein expression

Apoptosis is generally regulated by the various proapoptotic and antiapoptotic proteins. Generally apoptotic response is regulated by intrinsic apoptotic pathway (mitochondrial mediated) and extrinsic apoptotic pathway. It was reported that CAP induce apoptosis by increasing ROS levels, which is associated with intrinsic apoptotic pathway. We, therefore, observed the expression of various anti-apoptotic and pro-apoptotic proteins of intrinsic apoptotic pathway in MDA-MB453 cells. It was reported that, cancer cells resist apoptosis due to chemotherapeutic agents by upregulation of anti-apoptotic proteins and down regulation of apoptotic proteins. The Bcl2 family of proteins (Bcl-2, Bcl-xL and Mcl-1) and survivin are antiapoptotic proteins, which are responsible for chemoresistance. Bax, caspase-3, caspase-9 are some of the examples of pro-apoptotic proteins.<sup>25,26</sup> THP-CAP-LPs exhibited upregulation of pro-protein expressions of caspase-9, and downregulation of anti-apoptotic proteins such as Bcl2 and survivin, when compared with the CAP and CAP-LPs (Fig. 8).<sup>27</sup>

## Experimental

### Synthesis of THP-cholesterol conjugate (THP-CL)

The cholesterol peptide conjugate involves two steps: the solution of acryloyl chloride (1.3 mL, 15.6 mmol) in 5 mL of anhydrous THF was added dropwise to a solution of cholesterol (4 g, 10.3 mmol) and triethylamine (4.3 mL, 31 mmol) in 50 mL of anhydrous THF at 0 °C under a positive nitrogen flow. After removing the mixture from ice-bath, allowed to stir for overnight at room temperature. The crude solid was filtered out by using rotary evaporator and redissolved in 50 mL of DCM and washed with the following solvents like deionized water,

hydrochloric acid (0.5 M). The filtrate again extracted by using deionized water and finally neutralized with the sodium bicarbonate (1 M), deionised water and brine solution. The product present DCM was allowed to dry over anhydrous sodium sulphate and pure product was obtained as white solid by using column chromatography (DCM/hexane 1/1 v/v). The cholesterol-acrylate can be conjugated with peptide by using a mixture of DMSO and THF in the presence of a base triethylamine. The above mixture was allowed to stir at 37 °C for almost 2 days under inert conditions. The pure product was obtained by dialysis using deionized water, followed by freeze-drying.

### Preparation of THP-CAP-LPs

THP-CAP-LPs were prepared by thin film hydration technique by using THP as a lipid in the round bottom flask by using

Fig. 3 (a) Diagrammatic representation of the CAP loaded in the THP-CL to form THP-CAP-LPs by the use of thin film hydration technique. (b) Mass spectrum representing the conformation of the conjugation between the THP and CL. The  $[M + H]^+$  peak found at 2316.7.

Fig. 4 FT-IR graph (a), zeta potential of CAP-LPs (b) and THP-CAP-LPs (c), TEM images of CAP-LPs (d) and THP-CAP-LPs (e).

organic solvent chloroform and methanol in a ratio of 6 : 4 and kept for evaporation with rotary evaporator by using different parameter such as, vacuum pressure (160 mmHg to 30 mmHg), temperature (35 °C) and rotation speed (30 to 40 rpm) to get thin film. Afterwards, thin film consist round bottom flask has kept in vacuum oven for overnight at room temperature by using 160 mmHg vacuum pressure to evaporate remaining chemical residue from the thin film. Then prepared sample further, kept for hydration by using 7.4 pH dihydrogen orthophosphate buffer as hydration medium for 1 to 2 hours at rotary evaporator

and further, probe sonication has been done for 3 to 9 minutes to obtain desired particle size. CAP-LPs (non-surface modified LPs) were also prepared by same method except THP was replaced with cholesterol acrylate.

#### Application of central composite design (CCD) for optimization of THP-CAP-LPs

For the present study, a 17-run, 3-factor, 3-level CCD was employed to optimize the THP-CAP-LPs using Design-Expert software (Version 8.0.4. Stat-Ease, Inc., 2 Minneapolis, MN). This is a cubic design,

Fig. 5 Drug release profile of THP-CAP-LPs at different time points.

characterized by center point replicates and a set of points at the mid-point of each edge of the multidimensional cube that circumscribe the region of interest. Region of interest aids to investigate the main effects, interaction effects, and quadratic effects of the formulation ingredients and to optimize the formulation. Design matrix with 20 experimental runs was constructed. The amount of THP-CL ( $X_1$ ), CAP ( $X_2$ ), and sonication time ( $X_3$ ) as the independent variables which were represented by  $-1$ ,  $0$ , and  $+1$ , analogous to the low, middle, and high values, respectively as described in Table 1. The model was selected from a quadratic mathematical equation based on significance ( $p$  value  $< 0.05$ ) from the model and non-significant lack of fit.

#### Determination of particle size, zeta potential, and morphology

The particle size and zeta potential of THP-CAP-LPs and CAP-LPs were measured by dynamic light scattering (DLS) Nano-trac Wave™ (Microtrac, San Diego, CA, USA) before measurement the samples were suspended in deionized water. All measurements were carried out at  $25^\circ\text{C}$  and performed in triplicate. The morphology of THP-CAP-LPs was analysed using scanning electron microscopy (SEM) and transmission electron microscope (TEM).<sup>13,14</sup>

#### Determination of drug entrapment efficiency and drug loading

The amount of CAP in THP-CAP-LPs and CAP-LPs was determined using HPLC. About 10 mg prepared LPs in

freeze dried form was dissolved in 10 mL of 1 : 1 mixture of methanol and sodium dodecyl sulphate, that facilitate the disruption of coat to release the encapsulated drug. Then the mixture was placed in a super filter tube, and then centrifuged by a Sigma-3k30 Centrifuges (Sigma-Aldrich, Seelze, Germany) with 14 000 rpm for 10 min at the temperature of  $320^\circ\text{C}$ . The ultrafiltrate was extracted by methanol, and filtered with a 0.45 mm filter. The drug concentration in ultrafiltrate was determined as the content of the free drug.<sup>15</sup> The drug content in the supernatant after centrifugation was measured by HPLC method using an mobile phase delivery pump (LC-20 AD; Shimadzu, Japan) of flow rate  $1.2\text{ mL min}^{-1}$ , a photodiode array detector (SPDM20A; Shimadzu, Japan) set at 242 nm, a 20  $\mu\text{L}$  loop (Rheodyne) and Hypersil C18 (250 mm  $\times$  4.6 mm) was used. The mobile phase consisted of acetonitrile and potassium hydrogen orthophosphate buffer (pH 4) (60 : 40, v/v). The encapsulation efficiency and loading capacity were calculated by the following equations. The following formulae were used to determine DL (%) and EE (%).

$$\text{DL (\%)} = \frac{(\text{Total amount of drug} - \text{Amount of drug in aqueous phase})}{(\text{Amount of lipid}) \times 100}$$

$$\text{EE (\%)} = \frac{(\text{Total amount of drug} - \text{Amount of drug in aqueous phase})}{(\text{Total amount of drug}) \times 100}$$

#### Analysis of *in vitro* drug release

The *in vitro* release behaviour of THP-CAP-LPs and CAP-LPs was analysed by performing dialysis bag diffusion method. 1.0 mg of THP-CAP-LPs and CAP-LPs were dispersed in 10 mL of phosphate buffer saline (PBS) and then transferred into a pre-swelled dialysis bag with Molecular Weight Cut Off (MWCO) 8–12 kDa (Dialysis membrane-150, HiMedia, Mumbai, India). The bag was individually suspended in 100 mL of phosphate buffer saline (PBS) pH 4.5 and PBS pH 7.4, at  $37^\circ\text{C}$  in water bath at 100 rpm. Sink condition was maintained by periodically removing 2 mL sample and replacing equal volume of fresh buffer medium and monitored throughout the release period. The amount of CAP released was determined by an HPLC.

Fig. 6 The cellular uptake of CAP-LPs and THP-CAP-LPs in MDA-MB453 cells.

Fig. 7 The *in vitro* cytotoxic activity of CAP, CAP-LPs and THP-CAP-LPs.

### Cells and culture conditions

MDA-MB453 cells were procured from National Center for Cell Science (NCCS), Pune and cultured at humidified atmosphere of 95% air and 5% CO<sub>2</sub> at 37 °C.

### Cellular uptake study

MDA-MB 453 cells were incubated at 37 °C with THP-Rh-LPs/Rh-LPs (equivalent to 1 μg mL<sup>-1</sup> Rh) in complete media for 24 h then the cells were subjected to cytospinning and were fixed with 4% paraformaldehyde and mounted with DAPI. Cells were then visualized under confocal laser scanning microscopy (Carl Zeiss LSM710, Germany) to determine the cellular uptake.<sup>16–18</sup>

### *In vitro* cytotoxicity studies

The cytotoxicity of CAP, THP-CAP-LPs and CAP-LPs against MDA-MB 453 was measured by SRB assay.<sup>19</sup> Briefly, MDA-MB 453 cells with a density of (1 × 10<sup>4</sup> per well) were seeded in a 96-well plate and left for incubation for 24 h under a humidified atmosphere of 95% air and 5% CO<sub>2</sub> at 37 °C. Then, the cells were treated with serial concentrations (1.562, 3.125, 6.25, 12.5, 25, 50, 100 μM) of CAP, THP-CAP-LPs and CAP-LPs at

370 °C. The cells were rinsed with cell medium three times and further incubated at 370 °C for 72 h, followed by fixing of cells with cold trichloroacetic acid, washing and drying in the air. Subsequently, the fixed cells were then stained with 0.4% SRB dye for 30 min and the excess dye was washed by 1% acetic acid. After bound dye dissolved in 10 mM Tris base solution, the absorbance was determined using a Thermo scientific multi-scan FC microplate photometer at the wavelength of 540 nm. The data were expressed as the percentages of viable cells compared to the survival of control group (cells treated with medium) and presented as mean ± SD.

### Western blotting

RIPA buffer (comprising 20 mM NaH<sub>2</sub>PO<sub>4</sub>, 50 mM NaF, 2 mM EDTA, 150 mM NaCl, 1% deoxycholic acid, 0.1% SDS, pH 7.2) was used to prepare whole cell lysates. Protease inhibitor cocktail (Sigma Aldrich, Mumbai) was used for Western blot analysis. The protein (40 mg) was taken and resolved using 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE). Antibodies (anti-β-actin, anti-Bcl-2, anti-survivin, anti-caspase-9) were selected and obtained from Santacruz biotech and horseradish peroxidase-conjugated goat anti-rabbit IgG was used as secondary antibody. This was later detected using chemiluminescence reagents. Hitachi Gene tools CCD-BIO software with Hitachi scanning densitometry was used for determination of relative protein expression.<sup>12</sup>

### Statistical analysis

Statistical analysis was done by performing Student *t*-test. The differences were considered significant for *p* values of <0.05. Data were subjected to statistical analysis using Graphpad prism software (version 6).

## Conclusion

THP-CAP-LPs formulation which was optimized using Box-Behnken experimental design were prepared to overcome the bioavailability problems of CAP and then we have surface modified CAP-LPs with THP to form THP-CAP-LPs. Surface modification of CAP-LPs with THP significantly increased the uptake of CAP in MDA-MB 453 cells. CAP-LPs surface modified with THP promoted targeted therapy, therefore, overcome the bioavailability issues of CAP. THP-CAP-LPs exhibited greater cytotoxic effect when compared to CAP and CAP-LPs, which might be attributed to the ability of surface modification with THP to interfere with intrinsic apoptotic signalling pathways. It was observed that THP-CAP-LPs significantly downregulated anti-apoptotic proteins (Bcl2 and survivin), and upregulated pro-apoptotic caspase-9. Thereby we have assumed that the increased apoptotic ability of THP-CAP-LPs may be by interfering intrinsic apoptotic pathway. In conclusion, conjugation of THP with CAP-LPs is a promising targeted delivery of cytotoxic drugs reduces the off-target effects to healthy cells. In addition, THP-CAP-LPs delivery of cytotoxic agents will have improved antitumour activity when compared to either CAP-LPs or CAP alone. However, this study is a preliminary report of *in*

Fig. 8 Western blot analysis of various antiapoptotic and pro-apoptotic proteins.

*vitro* results, further targeted delivery to improve antitumour activity need to confirm *in vivo* in animal models.
