Inhibition of miR-16 enhances the sensitivity of fibroblast-like synovial cells to methotrexate by restraining MDR1/P-gp expression *via* NF- κ B pathway†

Jing Wang,^{ab} Ni Mao,^b Yiming Liu,^b Xi Xie,^b Jing Tian,^b Fen Li^b and Jinwei Chen ^{*b}

MicroRNAs (miRNAs) are demonstrated to contribute to the regulation of drug resistance in a number of diseases. Nevertheless, little is known about the role and the underlying mechanism of miR-16 in rheumatoid arthritis (RA) methotrexate resistance. In this study, we firstly examined the miR-16 expression in the serum and synovial fluid from RA patients who were unresponsive to methotrexate monotherapy (UR-MTX patients) and responsive RA patients (R-MTX patients). Secondly, the miR-16 expression was measured in both fibroblast-like synovial cells (FLS) and methotrexate resistance RA-FLS cells (FLS-MTX). FLS cells used in this study were isolated from synovial tissue specimens obtained from patients with RA who underwent total joint replacement. FLS-MTX cells were conducted by gradually increasing the concentration of methotrexate in the medium. The construction of FLS-MTX cells was confirmed by 3-(4,5)-dimethylthiazazo(-z-y1)-3,5-di-phenyltetrazoliumromide (MTT) assay. Thirdly, in order to further investigate the role of miR-16 in FLS-MTX cells, we introduced miR-16 inhibitor into FLS-MTX cells to knockdown the expression of miR-16, used fluorescence quantitative PCR to detect the inhibition efficiency. The effects of miR-16 inhibition on cell viability, cell cycle arrest and apoptosis in FLS-MTX cells were monitored with MTT and flow cytometry analysis, respectively. And the regulation of miR-16 on P-glycoprotein (P-gp) was performed using qRT-PCR, western blotting, and immunofluorescence staining. Fourthly, ammonium pyrrolidinedithiocarbamate (PDTC), a NF- κ B pathway inhibitor, was applied to verify the mechanism by which miR-16 involved in to regulate the P-gp expression, and thus contributing to the methotrexate resistance in FLS-MTX cells. MiR-16 was upregulated in the in serum and synovial fluid from UR-MTX patients as well as in FLS-MTX cells. Inhibition of miR-16 re-sensitized the FLS-MTX cells to methotrexate by suppressing the cell viability, cell promoting cycle arrest at G0/G1 phase and enhancing apoptosis. Knockdown of miR-16 significantly reduced MDR1 mRNA expression and P-gp protein expression in FLS-MTX cells. Furthermore, inhibition of NF- κ B pathway by PDTC reinforced the effect of miR-16 knockdown on P-gp expression, cell viability, cell cycle arrest and apoptosis. In conclusion, our study illustrated that inhibition of miR-16 in FLS-MTX cells alleviated methotrexate resistance by inhibiting MDR1/P-gp expression through inactivation of the NF- κ B pathway.

1. Introduction

Rheumatoid arthritis (RA) is a serious autoimmune disease characterized by chronic multi-joint inflammation with pain and swelling. The persistent development of rheumatoid arthritis can

lead to cartilage and bone damage, which can finally result in irreversible deformity and disability.¹ Though the incidence of RA has decreased significantly in recent decades, the prevalence of RA worldwide remains at 0.5% to 1.1%.² The key to effectively control the development of RA is early diagnosis and timely establishment of effective and active treatment. Methotrexate is a competitive inhibitor of dihydrofolate reductase, and low-dose methotrexate is recommended as the first-line pharmacotherapy for patients newly diagnosed with RA.³ However, there are significant differences in the efficacy of methotrexate among individual RA patients. Evidence suggests that 30% to 50% of RA patients are unresponsive/resistant to methotrexate treatment.^{4,5} So far, the mechanisms for unresponsiveness to methotrexate

treatment are complex and unclear. It has been proved that TGF- β signaling defect induced low expression of CD39 on Tregs could be a noninvasive biomarker for identifying MTX-resistant RA patients.^{6,7} Hence, understanding the methotrexate resistance would be of great importance and valuable to develop more effective therapies for RA patients.

MicroRNAs (miRNAs) are endogenous non-coding single-stranded small RNAs that have been widely found in eukaryotic cells in recent years.⁸ MiRNAs regulate post-transcriptional gene expression by binding to the 3' untranslated region (3' UTR) of target gene, thereby inhibiting the specific gene expression.⁹ Mounting evidences prove that dysregulation of miRNAs is involved in chemotherapeutic resistance in various diseases. miR-204 increases the sensitivity to arsenic trioxide in acute myeloid leukemia cells through enhancing cell apoptosis mediated by BIRC6/p53.¹⁰ Restoration of miR-431 *in vitro* reduces the half maximal inhibitory concentrations of doxorubicin and mitotane, and notably promotes the cell apoptosis in adrenocortical carcinoma.¹¹ MicroRNA-383 restrains doxorubicin resistance in hepatocellular carcinoma by targeting eukaryotic translation initiation factor 5A2.¹² Previous studies illustrated that miR-16 were increased in the sera of established RA patients in comparison with early RA.^{13,14} MiR-16 were shown to be over-expressed at the systemic level: in both the periphery and RA joints.¹⁵ Upregulation of miR-16 is demonstrated to be involved in Th17/Treg cell imbalance in patients with RA.¹⁶ miR-16 was suggested as a biomarker of RA.¹⁷ Therefore, we could conclude that miR-16 plays an important role in the occurrence and development of RA. Nevertheless, little work has been conducted to explore the relationship between miR-16 and methotrexate resistance in RA.

NF- κ B pathway was reported to be involved in RA progression. Carnosic acid could inhibit NF- κ B phosphorylation, thus cause the down-regulation of pro-inflammatory cytokines in RA.¹⁸ CD147 was capable of preventing TNF-induced apoptosis of FLS in RA by promoting the IKK/I κ B/NF- κ B signaling pathway.¹⁹ Insulin-like growth factor binding protein 3 reduced the inflammatory response and bone destruction by blocking NF- κ B activation and inducing apoptosis in RA FLS.²⁰ But whether NF- κ B contributed to resistance in RA remains unknown.

Here, we observed that the expression of miR-16 was elevated in serum and synovial fluid of RA patients who were unresponsive to methotrexate monotherapy (UR-MTX patients) and constructed methotrexate-resistant fibroblast-like synovial cells (FLS-MTX). Inhibition of miR-16 re-sensitized the FLS-MTX cells to methotrexate treatment. Moreover, knockdown of miR-16 significantly reduced P-gp expression at mRNA and protein levels in FLS-MTX cells. Additionally, inactivation of NF- κ B pathway by PDTC reinforced the effect of miR-16 knockdown on re-sensitizing the FLS-MTX cells to methotrexate treatment.

2. Materials and methods

2.1 Patient samples collection

Altogether 64 patients diagnosed with RA according to the criteria of the American College of Rheumatology were recruited

between July 2016 and December 2017 from the Department of Rheumatology and Immunology, The Second Xiangya Hospital of Central South University. All patients were newly diagnosed with RA, and before sample collection, all patients were treated with methotrexate monotherapy (15–20 mg per week) for at least four weeks. DAS28 (Disease Activity Score, including a 28-joint count) was applied to assess the RA activity. When DAS28 > 4.0, patients were stratified to be unresponsive RA patients (UR-MTX, $n = 32$); and when DAS28 < 3.0, patients were classified into responsive RA patients (R-MTX, $n = 32$). No other drugs were used before or during sample collection. All related experiments were performed in accordance with the Guidelines of Declaration of Helsinki, and Experiments were approved by the ethics committee of The Second Xiangya Hospital of Central South University. Informed consents were obtained from human participants of this study.

2.2 Cell culture and treatment

FLS were isolated from synovial tissue specimens obtained from an unresponsive RA patient who underwent total joint replacement. Fresh synovial tissue was cut into small pieces and digested with tissue enzyme digestion solution, following incubation with RPMI 1640 medium at 37 °C for six hours. Then, cells were maintained in complete RPMI 1640 medium supplemented with 10% fetal bovine serum (FBS). Cell culture medium was replaced every five days, and unadhered cells nonadherent cells were discarded. RA-FLS cells were grown, and cells at four to eight passages were used for the following experiments.

RA-FLS cells obtained above were used to construct methotrexate resistance cells. RA-FLS cells were cultured in complete RPMI 1640 medium supplemented with 10% FBS overnight, then the culture medium was replaced with complete medium added with 0.01 $\mu\text{g mL}^{-1}$ methotrexate to induce FLS cells to MDR following a gradual increase in the drug concentrations to 1.5 $\mu\text{g mL}^{-1}$. After eight months, the cells were able to steadily grow in the culture medium containing 1.5 $\mu\text{g mL}^{-1}$ methotrexate, and were named as FLS-MTX cells.

2.3 RNAs and cell transfection

MiR-16 inhibitor and its corresponding negative controls (NC) were derived from Gene-Pharma (Shanghai, China). MiR-16 inhibitor or NC was transfected into FLS-MTX cells with Lipofectamine 2000 (Invitrogen) according to the manufacturer's instructions.

2.4 3-(4,5)-dimethylthiazolium(z -y1)-3,5-diphenyltetrazoliumromide (MTT) assay

RA-FLS and FLS-MTX cells were seeded in quintuplicate at the density of 1×10^4 per well in 96-well plates and incubated overnight. And then cells were treated to with indicated concentrations of methotrexate. After incubating for 24 hours, 20 μL of MTT (Sigma, St. Louis, USA) solution (5 mg mL^{-1}) was added into each well, and incubated for another 4 hours. Cell supernatants were carefully removed after centrifugation, and cells in each well were dissolved in 200 μL of dimethyl sulfoxide

(DMSO). Optical density (OD) was measured at 570 nm with a microplate reader (Thermo Fisher Scientific, Waltham, MA, USA). Cell viability was calculated according to the following formulas: (OD value of the experimental group/OD value of the control group) \times 100%.

2.5 Cell cycle attest

Cells were centrifuged and collected 48 hours after transfection, and then cells were washed thrice with pre-cooled phosphate buffer saline (PBS) and fixed with 70% ethanol at 4 °C for 12 hours. Cells were washed with PBS again. Straight after, cells were incubated in 0.5 mL RNase A (50 $\mu\text{g mL}^{-1}$) for 30 minutes at 37 °C, and propidium iodide (PI) (50 $\mu\text{g mL}^{-1}$) was added and incubated for 30 minutes in the dark. Finally, cells were analyzed with flow cytometry analysis (Coulter Epics XL).

2.6 Cell apoptosis analysis

Cells were digested with trypsin (without EDTA), washed twice with PBS and centrifuged. Cells (3×10^5 cells per mL) were then resuspended in 500 μL binding buffer (7SeaPharmTech, Shanghai, China), 5 μL Annexin V-EGFP (7SeaPharmTech) and 5 μL PI (7SeaPharmTech) was added into cells for incubation for fifteen minutes at room temperature in the dark. And then the cells were analyzed by flow cytometry (guava easyCyte HT; EMD Millipore, Billerica, MA, USA).

2.7 Immunofluorescence staining

Cells were planted on cover slips and incubated in 24-well plates overnight. Before fixing with pre-cold 4% paraformaldehyde for twenty minutes, cells were washed twice with PBS softly. And then cells were permeabilized with 0.2% Triton X-100 in PBS for 10 minutes. After blocking with BSA for 30 minutes, cells were incubated with P-Glycoprotein Monoclonal Antibody (F4), (1 : 100; Thermo Fisher scientific) for overnight at 4 °C, followed by incubation with secondary antibody conjugated with FITC for 2 hours at room temperature in the dark. DAPI was employed to stain the nuclei. Fluorescence images were pictured with a CKX41 microscope (Olympus, Tokyo, Japan).

2.8 Reverse transcription and quantitation of miRNAs and mRNA by real-time PCR

Total RNA was isolated from serum/synovial fluid or cells using TRIzol Reagent according to the manufacturer's protocol (Invitrogen, CA, USA). 1 μg of total RNA was used to synthesize first strand cDNA with PrimeScript RT reagent kit (TaKaRa, Shiga, Japan). qPCR was conducted with the SYBR Premix Ex Taq (TaKaRa), and PCR-specific amplification was performed with ViiA™ 7 system (Thermo Fisher Scientific, Waltham, MA, USA). For quantification of miRNA expression, stem-loop RT-PCR was employed, and U6 was employed as an endogenous control. Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was used as endogenous control to mRNA.

2.9 Western blot analysis

Total protein of the cells was extracted with total protein extraction (Millipore, Bedford, MA, USA). Protein concentration was determined using the BCA protein assay kit. Cell lysates containing an equivalent amount of protein (10 μg) were electrophoresed through 12% SDS polyacrylamide gels, and subsequently transferred onto a nitrocellulose membrane (Sigma-Aldrich, Shanghai, China). Western blot analysis was performed with P-Glycoprotein Monoclonal Antibody (F4), (1 : 100; Thermo Fisher scientific), anti-IKB alpha (ab32518) (1 : 5000; Abcam), anti-IKB alpha (phospho S36) (ab133462), (1 : 50 000; Abcam), NFkB p50 Monoclonal Antibody (5D10D11) (1 : 1000; Thermo Fisher scientific), anti-NF- κ B p65 (ab16502) (1 : 5000; Abcam), GAPDH was used as an internal control. Afterwards, membrane was washed and incubated with horse-radish peroxidase (HRP)-conjugated secondary antibodies. Protein bands were photoed with ChemiDoc system (Bio-Rad). The expression levels of these proteins were quantified with Image J software.

2.10 Statistical analysis

All data are presented as the mean \pm standard deviation (SD) from 3 independent experiments. The difference between means of different groups was analyzed with Student's *t* test. SPSS 12.0 software (SPSS Inc., Chicago, IL, USA) was employed to conduct the statistical analysis. *P* value less than 0.05 was considered significant.

3. Results

3.1 miR-16 expression was evaluated in methotrexate resistant RA patients

Previous studies showed that levels of miR-16 increased (*p* = 0.008) after 3 months of therapy and was associated with the decrease in DAS28.¹³ Hence, we planted to figure out whether miR-16 is associated with methotrexate resistant in RA patients. We detected the miR-16 expression in serum and synovial fluid in R-MTX patients and UR-MTX patients by q-PCR. The data showed that miR-16 expression was significantly evaluated in the in serum and synovial fluid from UR-MTX patients than R-MTX patients (Fig. 1A and B).

3.2 miR-16 expression was up-regulated in methotrexate resistant RA-FLS cells

In order to investigate the role of miR-16 in methotrexate resistant RA-FLSs, we performed *in vitro* studies. Firstly, we constructed the methotrexate resistance RA-FLSs and named as FLS-MTX, and the RA-FLSs that have not undergone any additional processing were named as FLS. FLS and FLS-MTX cells were treated with different concentrations of methotrexate (0.001, 0.01, 0.1, 1.0 $\mu\text{g mL}^{-1}$) for 48 hours and MTT assay was used to detect the cell viability. As shown in Fig. 2A, compared with FLS, FLS-MTX cells exhibited stronger cell viability after the addition of methotrexate, and the significant difference between the two was more obvious with the increase of concentration. Besides, the IC₅₀ value of methotrexate was 0.178

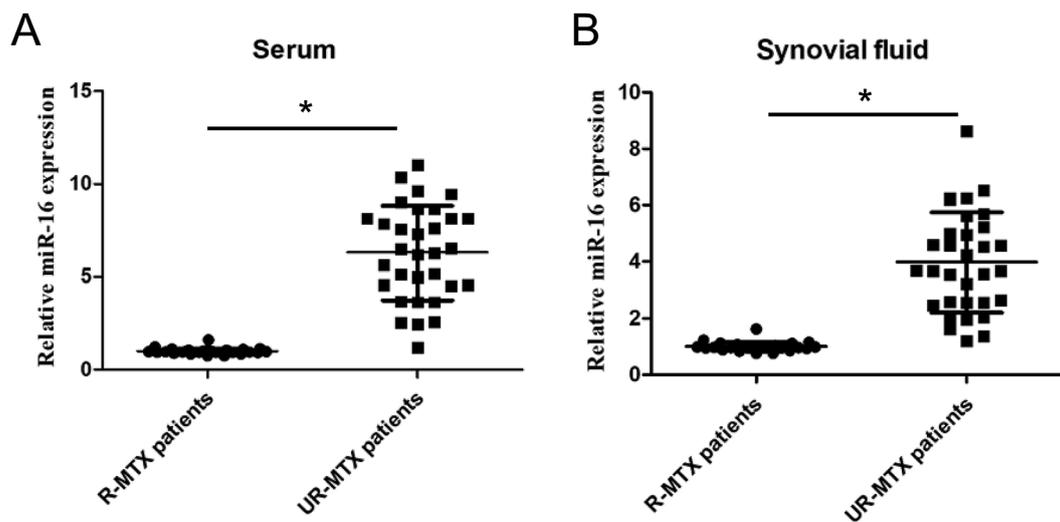

Fig. 1 miR-16 expression was evaluated in methotrexate resistant RA patients. miR-16 expression in serum (A) and synovial fluid (B) in R-MTX patients and UR-MTX patients by q-PCR. * $p < 0.5$ compared with R-MTX patients.

$\mu\text{g mL}^{-1}$ in the FLS cells, and $1.152 \mu\text{g mL}^{-1}$ in FLS-MTX cells. Therefore, the resistance index between FLS and FLS-MTX cells was calculated to be 6.472, indicating the successful construction of methotrexate-resistant strains. Secondly, we explored the miR-16 mRNA expression in FLS and FLS-MTX cells by qRT-PCR, and observed that the expression level of miR-16 in the FLS-MTX cells were observably boosted in comparison with FLS cells (Fig. 2B). These data manifested that miR-16 may be involved in chemoresistance in RA disease.

3.3 Suppression of miR-16 enhanced methotrexate sensitivity in methotrexate resistant RA-FLS cells

To explore the potential functions of miR-16 played on chemoresistance in RA, the miR-16 inhibitor or inhibitor NC were transfected into FLS-MTX cells respectively. qRT-PCR analysis showed that the expression level of miR-16 in the FLS-MTX cells was significantly restrained in miR-16 inhibitor group than NC

group (Fig. 3A), confirming the transfection efficiency. Subsequently, the cell viability of FLS-MTX cells transfected with miR-16 inhibitor or inhibitor NC were monitored by MTT assay after treating with different concentrations of methotrexate ($0.001, 0.01, 0.1, 1.0 \mu\text{g mL}^{-1}$) for 48 hours. The results showed that compared to inhibitor NC group, inhibition of miR-16 results in a significantly decreased cell viability as the concentration of methotrexate goes up (Fig. 3B), suggested that miR-16 suppression restored the sensitivity of FLS-MTX cells to methotrexate treatment. Then, cell cycle of FLS-MTX cells transfected with miR-16 inhibitor or inhibitor NC were evaluated with FCM analyses under $0.01 \mu\text{g mL}^{-1}$ methotrexate treatment. MiR-16 inhibition notably increased the cell proportion of G₀/G₁ phase of FLS-MTX cells (Fig. 3C), indicating that knockdown of miR-16 restrained the cell growth of FLS-MTX cells. Finally, apoptosis of FLS-MTX cells was analyzed *via* FCM analyses under $0.01 \mu\text{g mL}^{-1}$ methotrexate treatment. The data exhibited that the apoptotic rate in miR-16 inhibitor group was

All the experiments were repeated three times independently.

prominently enhanced compared to inhibitor NC groups (Fig. 3D), leading to the decreased number of FLS-MTX cells.

3.4 Suppression of miR-16 enhanced the sensitivity of FLS-MTX cells to methotrexate by inhibiting P-gp expression

To elucidate the molecular mechanisms of miR-16 is involved in the regulation of methotrexate resistant in RA-FLS cells, the well-known drug resistance related gene, MDR1, and its gene relative protein, P-gp were examined. The results of qRT-PCR and western blot analysis showed that suppression of miR-16 in FLS-MTX

cells decreased both MDR1/P-gp expression compared with inhibitor NC group (Fig. 4A and B). Meanwhile, the results of P-gp immunofluorescent staining revealed that the expression of P-gp was restrained by miR-16 knockdown (Fig. 4C).

3.5 Suppression of miR-16 restrained MDR1/P-gp expression by the NF- κ B pathway in FLS-MTX cells

Studies have proven that the NF- κ B pathway plays a regulatory role on MDR1 expression in cancer cells drug resistance.²¹ Hence, we hypothesized that miR-16 may play a fundamental

role in promoting P-gp expression through regulating NF- κ B pathway. PDTC, a NF- κ B pathway inhibitor, was applied to verify our hypothesis. The results of western blot showed that miR-16 inhibition decreased the expression of p-I κ B α , p50 and p65 in FLS-MTX cells, verifying that knockdown of miR-16 restrained the phosphorylation of NF- κ B pathway (Fig. 5A). The addition of PDTC in miR-16-knockdown-FLS-MTX cells further suppressed the P-gp expression (Fig. 5A), indicating that the P-gp expression was modulated by NF- κ B pathway in FLS-MTX cells. In addition, addition of PDTC prominently retarded the cell viability of miR-16-knockdown-FLS-MTX cells (Fig. 5B). Furthermore, the increase of cell proportion of G0/G1 phase of FLS-MTX cells induced by miR-16 inhibition was strengthened by additional treatment of PDTC (Fig. 5C), similar phenomenon was noted in apoptosis assay (Fig. 5D). Results above demonstrated that inhibition of miR-16 suppressed the P-gp expression through

inhibiting the NF- κ B pathway in FLS-MTX cells to restore the sensitivity of RA-FLS cells to methotrexate.

4. Discussion

Until now, it has been generally accepted that RA are primary caused by synovitis, which is characterized not only by the increased activity of lymphocytes and macrophages, but also by the number of synovial tissue-specific cells called fibroblast-like synovial cells (FLS).²² Stimulation and proliferation of FLS is thought to be the major underlying event in the joint inflammation and destruction in the process of RA.²³ Therefore, RA-FLS and the FLS-MTX was employed to investigate the drug resistance mechanism of RA.

miR-16 was reported to participate in a series of pathophysiological processes. Combination of vitamin B12 active

forms facilitated fetal growth by enhancing placental miR-16 and miR-21 expression levels in Wistar rats.²⁴ In a rat model of depression, reflecting raphe miR-16 level, cerebrospinal fluid miR-16 was involved in the pathogenesis of depression and regulated raphe serotonin transporter expression.²⁵ MiR-16 regulated myoblast proliferation and apoptosis by targeting SESN1, and thus contributed to myoblast differentiation.²⁶ Some reports have described that miR-16 was also involved in the regulation of drug resistance in diseases. MiR-16 was verified to down-regulated in astrocytic gliomas, and miR-16-5p overexpression increased sensitivity to irradiation and TMZ in A172 glioma cells.²⁷ Levels of miR-16 were the lowest in serum of Multi Drug Resistant (MDR) tuberculosis patients and associate with responses to drug therapy.²⁸ Forced expression of

miR-16 sensitized the ErbB-2-positive breast and gastric cancer to trastuzumab and lapatinib therapy *via* targeting CCNJ and FUBP1.²⁹ Previous studies illustrated that miR-16 were increased in the sera of established RA patients in comparison with early RA.^{13,14} However, whether miR-16 is involved in chemoresistance in RA remains uncertain. In this study, we observed that miR-16 expression was notably upregulated in the serum and synovial fluid of methotrexate-resistant RA patient than methotrexate-sensitive RA patient. Meanwhile, the miR-16 was shown upregulated in FLS-MTX cells in comparison with normal RA-FLS cells. These results suggested that the expression of miR-16 is most likely related to the methotrexate resistance in RA. In addition, the CCK-8 assay suggested that miR-16 suppression restored the sensitivity of FLS-MTX cells to

methotrexate treatment. Flow cytometry illustrated that miR-16 inhibition increased the cell proportion of G0/G1 phase and enhanced apoptosis of FLS-MTX cells. These data implied that knockdown of miR-16 may weaken the methotrexate resistance of FLS-MTX cells.

P-Glycoprotein (P-gp), encoded by MDR1, is the most classical and most studied transmembrane transporter associated with MDR. Targeting P-gp to improve the sensitivity of chemotherapy has been widely used in the treatment of various drug-resistant diseases.^{30,31} Studies showed that RA patients with disease-modifying antirheumatic drugs (DMARD) failure had higher serum P-gp levels than patients with a therapeutic response, and high P-gp levels increased the risk of DMARD failure.³² These studies suggested that P-gp may be a therapeutic target to reverse drug resistance, restore and enhance drug sensitivity of anti-rheumatic drugs. Here, we illustrated that inhibition of miR-16 effectively reduced MDR1/P-gp expression, resulting in moderation of the methotrexate resistant in FLS-MTX cells. These results suggested that inhibition of miR-16 enhances methotrexate-resistance by down-regulating the expression of MDR1/P-gp in RA.

MDR1 is the downstream gene of NF- κ B pathway, and the transcription of MDR1 is activated under the regulation of NF- κ B, leading to the excessive expression of P-gp, which in turn leads to MDR.²¹ NF- κ B has been demonstrated to regulate the expression of MDR1 gene in many cell lines. RY10-4 application suppressed the MDR in MCF-7/ADR cells by P-gp down-regulation through the PI3K/Akt/NF- κ B pathway.³³ Chronic inflammation increased P-gp expression in peripheral mononuclear blood cells *via* the STAT3/Nf- κ b pathway in colitis mice.³⁴ Here, we showed that miR-16 inhibition decreased the expression of p-I κ B α , p50 and p65 in FLS-MTX cells. NF- κ B inactivation by PDTC in miR-16-knockdown-FLS-MTX cells further suppressed the P-gp expression, confirming that the P-gp expression was modulated by NF- κ B pathway in FLS-MTX cells. Furthermore, addition of PDTC prominently retarded the cell viability, further increase cell proportion of G0/G1 phase and apoptosis in miR-16-knockdown-FLS-MTX cells, indicating that inhibition of miR-16 suppressed the P-gp expression through inhibiting the NF- κ B pathway in FLS-MTX cells to restore the sensitivity of RA-FLS cells.

5. Conclusion

In general, we verified that the miR-16 expression was significantly increased in the serum and synovial fluid of methotrexate-resistant RA patient and FLS-MTX cells. Most importantly, inhibition of miR-16 enhances methotrexate sensitivity by restraining P-gp protein *via* NF- κ B pathway in FLS-MTX cells. These results suggested that a combination of miR-16 inhibitor and methotrexate might be an effective strategy for the RA treatment.
