Ru(II)–N-heterocyclic carbene complexes: synthesis, characterization, transfer hydrogenation reactions and biological determination†

Lamia Boubakri,^a A. Chakchouk-Mtibaa,^b Abdullah S. Al-Ayed,^c L. Mansour,^d Nael Abutaha,^d Abdel Halim Harrath,^d L. Mellouli,^b I. Özdemir,^b S. Yasar^e and Naceur Hamdi^{id}*^{ac}

A series of ruthenium(II) complexes with N-heterocyclic carbene ligands were successfully synthesized by transmetalation reactions between silver(I) N-heterocyclic carbene complexes and [RuCl₂(p-cymene)]₂ in dichloromethane under Ar conditions. All new compounds were characterized by spectroscopic and analytical methods. These ruthenium(II)–NHC complexes were found to be efficient precatalysts for the transfer hydrogenation of ketones by using 2-propanol as the hydrogen source in the presence of KOH as a co-catalyst. The antibacterial activity of ruthenium N-heterocyclic carbene complexes **3a–f** was measured by disc diffusion method against Gram positive and Gram-negative bacteria. Compounds **3d** exhibited potential antibacterial activity against five bacterial species among the six used as indicator cells. The product **3e** inhibits the growth of all the six tested microorganisms. Moreover, the antioxidant activity determination of these complexes **3a–f**, using 2,2-diphenyl-1-picrylhydrazyl (DPPH) and 2,2'-azino-bis-3-ethylbenzothiazoline-6-sulphonic acid (ABTS) as reagent, showed that compounds **3b** and **3d** possess DPPH and ABTS antiradical activities. From a concentration of 1 mg ml^{−1}, these two complexes presented a similar scavenging activity to that of the two used controls gallic acid (GA) and butylated hydroxytoluene (BHT). From a concentration of 10 mg ml^{−1}, the percentage inhibition of complexes **3b** and **3d** was respectively 70% and 90%. In addition, these two Ru–NHC complexes exhibited antifungal activity against *Candida albicans*. Investigation of the anti-acetylcholinesterase activity of the studied complexes showed that compounds **3a**, **3b**, **3d** and **3e** exhibited good activity at 100 µg ml^{−1} and product **3d** is the most active. In a cytotoxicity study the complexes **3** were evaluated against two human cancer cell lines MDA-MB-231 and MCF-7. Both **3d** and **3e** complexes were found to be active against the tested cell lines showing comparable activity with examples in the literature.

1. Introduction

Transfer hydrogenation, a potentially useful protocol for the reduction of ketones and aldehydes to their corresponding alcohols, has been extensively studied.¹ A large number of studies have appeared with transition metal-catalyzed

enantioselective hydrogenation of ketones using 2-propanol or formic acid under basic conditions,^{2,3} because the method has advantages, such as low cost, ease of handling, and high solubility of 2-propanol or formic acid as a hydrogen-donor reagent. The most active and versatile homogeneous catalytic secondary alcohol/ketone oxidation/reduction systems are the metal-ligand bifunctional ruthenium complexes developed by Noyori and co-workers.^{4–6} A variety of related ligands and transition metal complex catalysts have been developed for this purpose.^{7,8} One of these ruthenium complexes is Ru(NHC) (NHC: N-heterocyclic carbene). N-heterocyclic carbene ligands appear particularly suited to this purpose, in that their ruthenium(II) complexes possess high thermal and hydrolytic stability.⁹

Ligand effects are extremely important in homogeneous catalysis by metal complexes. Carbenes are both reactive intermediates and ligands in catalysis. After the first stable N-heterocyclic carbene ligands were reported by Arduengo *et al.*, N-heterocyclic carbenes (NHCs) have been indispensable ligands for transition metals and homogeneous catalysis.^{10–12}

Scheme 1 Synthesis of ruthenium–NHC carbene complexes (**3a–f**).

Due to their topological and electronic versatility, N-heterocyclic carbene-based ligands have widespread applications not only in organometallic chemistry but also in industrial applications of

homogeneous catalysis. Strong σ -donation from NHCs increases the stability of the complexes and gives complexes with advantageous properties in catalytic reactions.^{13–15} The first

Fig. 1 Structure of ruthenium–NHC carbene complexes **3(a–f)**.

catalytic applications of NHC complexes were reported by Herrmann in 1995, together with the recognition that NHCs are excellent ligands for many homogeneous catalysts.¹¹ Different NHC complexes and their catalytic applications have been reported by many research groups.^{16–24} Continued research has focused on synthesis of new functional NHC complexes. Functionality of the complexes depends on the steric and electronic effect of the ligands on the metal center. Ru–NHC complexes can be functionalized by N-substituted NHC ligands. In this context, our research group has focused on synthesis, characterization, and catalytic activity of functional N-heterocyclic carbene ligands and their metal complexes.^{25–28}

2. Results and discussion

2.1. Preparation of Ru–NHC complexes (3a–f)

Silver complexes of N-heterocyclic carbenes were prepared by the addition of Ag₂O to 5,6-dimethylbenzimidazolium salts solutions (1a–f) in CH₂Cl₂ under exclusion of light at room temperature (Scheme 1 and Fig. 1). White solid (in 75–90% yield) were isolated.²⁹ When the white solid were left in air, they began to slowly turn black. Low field signals attributed to acidic NCHN protons were not observed in the ¹H NMR spectra of the new Ag–NHC complexes (2a–f). This observation confirmed that the 5,6-dimethylbenzimidazolium salts were deprotonated. However, coordination of N-heterocyclic carbene ligands to the metal center resulted in low field resonances for carbene carbon.²⁹

All Ag–NHC complexes are widely used for the next reaction as transfer compounds. To show the feasibility of this approach for 2a–f, a series of Ru(II)–NHC complexes were synthesized in good yield as stable red solids. 3a–f were obtained by reaction of [RuCl₂(*p*-cymene)]₂ with a solution of 2a–f in the dark at room

temperature (Scheme 1). The air and moisture-stable ruthenium N-heterocyclic carbene complexes (3a–f) isolated in high purity after recrystallization with DCM/ether, were soluble in solvents such as dichloromethane, chloroform, toluene, and tetrahydrofuran and insoluble in nonpolar solvents (Fig. 1).³⁰

The ruthenium–NHC complexes 3a–f were characterized by NMR (¹H and ¹³C), IR, and DART-TOF mass spectrometry. The ¹H-NMR spectra of complex 3a was recorded in CDCl₃ at room temperature. Here, the proton H_{7'''} of the isopropyl group of *p*-cymene was seen as a multiplet at 2.62 ppm (Fig. 2).

The aromatic protons appeared between 5.54 and 6.91 ppm as a multiplet while methylic protons appeared between 1.14 and 2.30 ppm as singlets. In the ¹H-NMR spectra of 3a, (NCH₂) was resonated at 5.29 and 5.05 ppm as a doublet.

The spectra of these products in CDCl₃ supported the successful formation of the ruthenium complexes because of the absence of NCHN signal proton in a downfield for 2–3.

The ¹H and ¹³C NMR spectra of these new complexes (3a–f) are consistent with the proposed formula. ¹³C{¹H} NMR spectra prove an increasing downfield shift of the characteristic peak of the carbenic carbon resonance from 2a–f to 3a–f: for example, the ¹³C{¹H}N–C–N shifts of 3a displays as a singlet at 188.8 ppm which confirmed the transmetallation between silver and ruthenium (Fig. 3).³¹

The results of the mass spectrometry analyses are proof verification of the synthesized compounds (Fig. 4).

The fragmentation leading to the *m/z* = 279 and *m/z* = 343 ions can occur by the mechanisms shown in Scheme 2.

2.2. Transfer hydrogenation

The transfer hydrogenation process, which involves hydrogen transfer from a donor to an acceptor, has become one of the most important synthetic routes for producing alcohols from

Fig. 2 ^1H NMR spectra of Ru(II)-N-heterocyclic carbene complexes **3a** (CDCl_3 , 300 MHz).

ketones.³² Non-toxic reagents, green solvents and mild reaction conditions are remarkable features of transfer hydrogenation reactions.³³ Transition-metal catalyzed transfer hydrogenation using 2-propanol and KOH as a hydrogen source and promoter respectively, has become an efficient method in organic synthesis as illustrated by several useful applications reported in recent years.³⁴ The reaction conditions for this important process are easy to handle (moderate boiling point 82 °C), inexpensive, relatively mild and environmentally benign.³⁰

As part of our ongoing investigation into novel functionalized NHC ligands as the supporting environment for metal complexes and their application in catalysis. We herein report a series of catalytic transfer hydrogenation reactions employing the ruthenium-NHC complexes to discover their benefits. The transfer hydrogenation reactions are very susceptible to the type of the base and its concentration.³¹ As the starting point, the performance of the catalysts in the transfer hydrogenation was screened by using acetophenone as a model substrate.^{30,31,33} Previously, our laboratory reported the application of ruthenium-NHC complexes in the transfer hydrogenation of ketones.³⁰ According to the literature, in a typical experiment, we dissolved the preformed, isolated crystalline catalyst (0.005 mmol) in 2-propanol. After the catalysts had completely dissolved, ketone (0.5 mmol) and a KOH (2 mmol) were added and the reaction was performed at 80 °C in 1 h.

In this context, we investigated the nature of the catalysts and the substrate that could impact on yield in the transfer hydrogenation reaction. Catalyst performance depends on the nature of substrates, the behavior of the ligands in the complexes, and concentration of the catalyst. Electrophilic effect of the substrate, nature of the catalysts, donor function, and flexibility of the backbone in the NHC ligands can be responsible for activity of the complexes. Steric and electronic properties of the substrates also affect conversions. Acetophenone and *p*-chloroacetophenone reacted very cleanly and turned into corresponding alcohol in good yields (Table 1, entries 1–6). However, **3b** complex exhibited the lowest catalytic activity with all ketones. This low catalytic activity was attributed to structure of complex **3b**, presumably due to decreased steric bulk around the metal or lower electron donation provided by the carbene ligands (Table 1, entries 2, 5, 8, 11 and 14). When *p*-methoxyacetophenone was used as substrate, low yield was observed on the transfer hydrogenation reaction catalysed by **3a–c** (Table 1, entries 10–12). We are of the opinion that the nature of substrate can also give rise to low yield. Substrates bearing electron-withdrawing groups (Table 1, entries 4–9) were reduced to secondary alcohols in better yield than substrates bearing electron-donating groups (Table 1, entries 10–12). Similarly, with only 0.5 mol% of the same catalysts, it was possible to hydrogenate cyclohexanone and obtain

Fig. 3 ^{13}C NMR spectra of Ru(II)-N-heterocyclic carbene complexes **3a** (CDCl_3 , 75 MHz).

the corresponding alcohols with the highest yields (Table 1, entries 13–15).

3. Biological activities

3.1. Antibacterial activity

The synthesized complexes were examined *in vitro* for their antibacterial activity using the well diffusion method (Fig. 5). Ampicillin (AMC) was used as standard control drugs for antibacterial activity. The ruthenium-NHC complexes (**3a–f**) were

evaluated against three Gram-positive bacteria (*Micrococcus luteus* LB14110, *Listeria monocytogenes* ATCC19117, *Staphylococcus aureus* ATCC6538) and three Gram-negative bacteria (*Salmonella typhimurium* ATCC14028, *Pseudomonas aeruginosa* ATCC 9189, *Escherichia coli*). The obtained antibacterial activity is presented in Fig. 6 and Table 2.

Globally, all complexes tested showed an important antibacterial activity against the *Micrococcus luteus* LB14110. Although complex **3d** presents the highest inhibitory effect. In addition, **3e** inhibit the growth of Gram-positive and Gram-

Fig. 4 DART-TOF-MS of Ru(II)-N-heterocyclic carbene complexes **3a**.

Scheme 2 Mechanism of fragmentation leading to peaks $m/z = 225$.

negative bacteria in high and low concentrations. In contrast, the other complexes show no activity against *E. coli*.

The antibacterial activity of ruthenium–N-heterocyclic carbene complexes (3a–f) was reported in terms of the MIC values, defined as the lowest concentration of an antibacterial that visibly inhibits the growth of the bacteria after an overnight incubation. The MICs values complexes 3 were determined

against the two Gram positive bacteria *Micrococcus luteus* LB 14110 and *Listeria monocytogenes* ATCC 19117 and the Gram-negative bacterium *Salmonella typhimurium* ATCC 14028. As shown in Table 3, the MICs values range from 0.0195–0.625 mg ml^{−1} for *Micrococcus luteus* LB 14110; 0.0781–5 mg ml^{−1} for *Listeria monocytogenes* ATCC 19117 and *Salmonella typhimurium* ATCC 14028. The most active compound was 3d which presents

against *Salmonella typhimurium* ATCC 14028 the lowest MIC value ($0.0781 \text{ mg ml}^{-1}$) than the used standard (ampicillin). Thus, the best activity was recorded for this complex with MIC values of $0.0195 \text{ mg ml}^{-1}$ against *Micrococcus luteus* LB14110. Complex 3e also has MIC values of $0.0781 \text{ mg ml}^{-1}$ against *Listeria monocytogenes* ATCC 19117.

3.2. Antioxidant activity

3.2.1. Antiradical test: DPPH. The proton radical scavenging action is known to be one of the various mechanisms for antioxidation. DPPH (1,1-diphenyl-2-picrylhydrazyl) is one of the compounds that possess a proton free radical and shows a characteristic absorption at 517 nm (purple). When DPPH encounters proton radical scavengers, its purple color would fade rapidly. Among all free radicals, the hydroxyl radical is by far the most potent and therefore the most dangerous oxygen metabolite which would result in cell membrane disintegration, membrane protein damage, DNA mutation and further initiate or propagate the development of many diseases. Elimination of this radical is one of the major aims of antioxidant administration.³⁵ Current research has shown that some antioxidants could act as the inducers of DNA damage response, which leads to cell death.³⁶ In present study, the scavenging activity of the synthesized Ru-NHC complexes (3a–

f) on the DPPH radical were investigated. As shown in Fig. 7, the complexes 3b and 3d present a higher antioxidant activity than other complexes which no antioxidant activity was observed. From the results, we can see that, within the range of tested concentration, the average suppression ratios of DPPH increase along with the increase of the complex concentration (Fig. 7). Concerning complexes 3b and 3d, from a concentration of 1 mg ml^{-1} , the scavenging activity was very similar to that of the two used control gallic acid (GA) and butylated hydroxytoluene (BHT) known as very good antioxidant compounds.

3.2.2. Antiradical test: ABTS. The dark blue color of ABTS (ammonium salt of 2,2'-azinobis-3-ethylbenzothiazoline-6-sulphonic acid) turns very dark blue and may even become colorless if there are radical scavengers free. This discoloration is based on the oxidation of the conjugated organic structure in radical cation $\text{ABTS}^{+\cdot}$. To carry out the ABTS trapping test, $20 \mu\text{l}$ of the synthesized products were added to $18 \mu\text{l}$ of the prepared $\text{ABTS}^{+\cdot}$ solution, while stirring vigorously for 30 seconds. The resulting solution was mixed with ethanol and ultrapure water (5 : 5) v/v. Tubes containing volumes of equivalent amounts of the different complexes are incubated under incubation and controlled for 6 min in the dark. After a sweep, the wavelength of the

Fig. 6 The method of determining the MIC.

work chosen for the evaluation of the antiradical activity was set at 734 nm. In order to explore the experimental results obtained, it is necessary to calculate the percentages of inhibition of the free radical $ABTS^{+}$ according to the following formula:

$$AAOx\% = [(A_c - A_s)/A_c] \times 100$$

A_c : absorbance of control; A_s : absorbance of the sample.

As shown in Fig. 8, complexes **3b** and **3d** present a high antioxidant activity. Concerning the compound **3b**, from a concentration of 10 mg ml^{-1} the percentage inhibition was in order to 70%. For compound **3d**, the percentage inhibition was in order to 90%.

3.3. Antifungal activity

Fungal pathology has increased in recent years due to the increase in deep, visceral and septicemic mycotic sites. The former are caused by fungi that are widespread in nature, usually saprophytic, becoming pathogenic only under certain

conditions: increasing use of broad-spectrum antibiotics, patients with AIDS; we talk about iatrogenic mycoses. They are caused by so-called opportunistic fungi that are either levuriform (*Candida*, *Cryptococcus*) or filamentous (*Aspergillus*, *Cephalosporium*).³⁷ The development of antifungals comes up against obstacles such as the weak fungicidal activity *in vivo* compared to the results *in vitro* and the poor diffusion through the very thick wall of the mushrooms because of its composition (chitin, phospholipids, and sterols); these constituents are absent in bacteria, which explains why most antibacterial antibiotics are not antifungals.

To evaluate the antifungal activity of the Ru-NHC complexes (**3a-f**) with respect to the *Candida albicans* strain, the solid medium diffusion method was carried out (Fig. 9). As shown in Table 4, the complexes **3a**, **3c**, **3e** and **3f** are completely inactive against *Candida albicans*. The compounds **3b** and **3d** present a high antifungal activity. The most active compound was **3d** which presents against *Candida albicans* the highest diameter of growth inhibition zone with a value of the order of $34 \pm 0.18 \text{ mm}$.

3.4. Acetylcholinesterase inhibition

The acetylcholinesterase enzyme (AChE) is an attractive target for the rational drug design and for the discovery of mechanism-based inhibitors because of its role in the hydrolysis of the neurotransmitter acetylcholine (ACh). The pathogenesis of Alzheimer's disease (AD) has been linked to a deficiency in the brain neurotransmitter acetylcholine. Subsequently, acetylcholinesterase inhibitors (AChEIs) were introduced for the symptomatic treatment of AD,^{38,39} and other possible therapeutic applications in the treatment of

Parkinson's disease, senile dementia, and ataxia, among others.⁴⁰ The prevailing view has been that the efficacy of AChEIs is attained through their augmentation of acetylcholine-mediated neuron to neuron transmission. However, AChEIs also protect cells from free radical toxicity and β -amyloid induced injury and increased production of antioxidants.

The results presented in Table 5 show that the **3d** complex is the most potent inhibitor against AChE. This good activity is confirmed by a value of the percentage inhibition of the order of 47.1%. However, the **3c** and **3f** complexes are completely inactive and the other Ru–NHC complexes exhibit anti-AChEI activity.

3.5. Anticancer activity

3.5.1. Cytotoxicity assay. Cytotoxicity of compounds was assessed using MTT assay on MDA-MB-231 cells and MCF7 cells as carried out previously (Song *et al.*, 2010).⁴¹ In brief, cells were cultured into 96-well plates (Corning, USA) at a density of 5×10^5 cells per well in 200 μ l medium. After 24 h, cells were treated with different concentrations (10, 5, 2.5, 1 μ g ml^{−1}) of compounds and further incubated for 48 h to evaluate the cytotoxicity of compounds. At the end of incubation period, 20 μ l MTT solution was added to each well and cells were further incubated for 2 h at 37 °C. Finally, the media were aspirated and then 200 μ l 0.1% HCl–MeOH was added to dissolve formazan crystals. The OD value was read at 490 nm on a microplate reader (Thermo Multiskan FC, China). MeOH-treated cells were

Fig. 7 Scavenging activity of compounds **3b** and **3d** on DPPH radicals.

Fig. 8 Percent inhibition of complexes **3b** and **3d** as a function of concentration.

used as controls. The relative cell viability was calculated using the following formula:

$$\text{Relative cell viability (\%)} = \text{OD treated C/OD control} \times 100\%$$

3.5.2. Disc diffusion method. *Escherichia coli* (ATCC10418), and methicillin-resistant *Staphylococcus aureus* (MRSA) (ATCC3359) were grown on nutrient agar plates (HiMedia, India) and *Candida albicans* (ATCC 90028) was grown on potato dextrose agar (HiMedia, India) for 24 h at 35 °C. All cultures were obtained from the American Type Culture Collection (ATCC). The disc diffusion method was used to assess the antimicrobial activities (De Beer and Sherwood, 1945).⁴² Microbes were suspended in sterile saline solution (0.9%) and the turbidity was adjusted to 0.5 OD value using spectrophotometer (Labomed Inc., USA). The inoculum was swabbed on the surface of agar plates used using a sterilized cotton swab. Sterile blank disks (6 mm) were loaded with 10 µl of compounds stock solution (10 mg ml⁻¹) giving a concentration of 50 µg per disc. Commercial tetracycline discs (30 µg per disc) were used as

Table 4 Minimum Inhibitory Concentrations (MICs) expressed in mg ml⁻¹

Strain	Compounds

positive controls and methanol as a negative control for comparison. The Petri-plates were incubated at 35 °C for 24 hours. The diameters of the zones of inhibition produced by the compounds on the test isolates were measured in mm.

The compounds were screened calorimetrically using 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) cell assay in two human cancer cell lines namely MCF7 and MDA-MB-231 to evaluate their cytotoxicity. As shown in Table 6, many of the compounds affected cell viability of cancer cell lines and showed promising level of cytotoxicity however, the cytotoxicity of **3e** and **3d** was much stronger in MCF7 with IC₅₀ values 0.68 and 0.6 µg ml⁻¹, respectively as compared to their activity on MDA-MB-231 cells. The cytotoxicity of **3e** and **3d** on MDA-MB-231 cells was 1.93 and 3.1 µg ml⁻¹. The cytotoxicity of compounds **3c** in MCF7 and MDA-MB-231 cells was 1.7 and 16 µg ml⁻¹, while the IC₅₀ values of compound on **3f** were 1.3 and 3.3 µg ml⁻¹ against MCF7 and MDA-MB-231, respectively.

The antimicrobial activities of the synthesized compounds against the human pathogenic microorganisms are presented in Table 6. The results revealed that the highest antimicrobial activity was reported in **3e** (against *E. coli*) followed **3d** (against *E. coli*) and **3b** (against MRSA) however the highest anti *Candida albicans* activity was found in **3d** (30.5 mm) followed by **3b** (28.0 mm) and **3a** (25.0 mm). Compound **3c** was completely inactive against the three strains (Table 6).

4. Conclusion

In summary, a new series of ruthenium–NHC complexes (3a–f) have been synthesized from silver–NHC complexes with $[\text{RuCl}_2(p\text{-cymene})]_2$. All these compounds were characterized by spectroscopic and analytic techniques. To demonstrate the efficiency of 3a–c as catalyst precursors, transfer hydrogenations of ketones were performed. Excellent activity and good catalyst stability were observed under mild reaction conditions. Structural differences in 3a–c did not affect yields significantly. The Ru–NHC catalysts described here gave one of the highest conversion rates to date for transfer hydrogenation reaction catalyzed by Ru–NHC complexes with low base loading.

The complexes 3a–f were tested for their antibacterial activity against *Micrococcus luteus* LB 14110, *Staphylococcus aureus* ATCC 6538, *Listeria monocytogenes* ATCC 19117, *Salmonella typhimurium* ATCC 14028, *Pseudomonas aeruginosa* ATCC 49189 and *E. coli*. Obtained results show that the complexes 3d and 3e have an effective antibacterial activity against the used indicator bacteria. With regard to the scavenging activity of the synthesized complexes on the DPPH radical, we noted that compounds 3b and 3d, from a concentration of 1 mg ml^{-1} , present a very similar scavenging activity to that of the two used controls butylated hydroxytoluene (BHT) and gallic acid (GA). Interestingly, from a concentration of 10 mg ml^{-1} , 3b and 3d complexes exhibited the percentage inhibition in order to 70% and 90% respectively. Concerning acetylcholinesterase inhibition activity (AChEI), according to our findings, compound 3d presents an interesting AChEI activity with 47.1% of inhibition. In addition, this complex presents against *Candida albicans* the highest diameter of growth inhibition zone with a value of the order of 34 \pm 0.18 mm. The cytotoxic activity of the complexes (3a–f) was also determined against a panel of cell lines such as MDA-MB-231 and T47D. The most active compounds are 3d and 3e.

5. Experimental section

5.1. Materials and methods

All procedures were carried out under an inert atmosphere using standard Schlenk line techniques. Chemicals and solvents were purchased from Sigma Aldrich. The solvents used were purified

and dried by MBraun SPS 800 solvent purification system. Column chromatography was performed by using silica gel 60 (70–230 mesh). ^1H NMR and ^{13}C NMR spectra were recorded at 300 MHz (^1H), 75 MHz (^{13}C) in CDCl_3 with tetramethylsilane as an internal reference. The NMR studies were carried out in high-quality 5 mm NMR tubes. Signals are quoted in parts per million as δ downfield from tetramethylsilane ($\delta = 0.00$) as an internal standard. NMR multiplicities are abbreviated as follows: s = singlet, d = doublet, t = triplet, m = multiplet. GC analyses of reactions mixtures have been done using a Shimadzu GC 2010-Plus GCFID system. Column: Teknokroma TRB-5 capillary column, 30 m \times 0.32 mm \times 0.25 μm . Initial temperature at 50 $^\circ\text{C}$, held for 1 min, ramp 2 $^\circ\text{C min}^{-1}$ next 90 $^\circ\text{C}$, held for 3 min, ramp 40 $^\circ\text{C min}^{-1}$ next 240 $^\circ\text{C}$ held for 10 min. The temperature of the injector and detector were held at 240 $^\circ\text{C}$. Melting points were determined with Kofler bench at Isste of Borj Cedria (Hammam Lif, University of Carthage, Borj Cedria, Tunisia).

5.2. General procedure for preparation of the ruthenium–NHC complexes (3a–f)

The ruthenium–NHC complexes were synthesized through transmetalation *via* silver–NHC complexes (2a–f). We reacted one equivalent of silver–NHC complexes and 0.5 equivalent of $[\text{RuCl}_2(p\text{-cymene})]_2$ in anhydrous dichloromethane (30 ml). The reaction mixture was stirred for 4 days at room temperature in the dark. Then the solution was filtered through Celite and the filtrate was concentrated to dryness in vacuum. The red solid obtained recrystallized from DCM–diethyl ether or DCM–pentane. The structure of Ru–NHC complexes were determined by IR and NMR analysis.

5.3. Dichloro-[1,3-bis(3,5-dimethylbenzyl)-benzimidazole-2-ylidene](*p*-cymene)ruthenium(II), 3a

Yield: (85%); mp 236 $^\circ\text{C}$. $\text{C}_{37}\text{H}_{45}\text{Cl}_2\text{N}_2\text{Ru}$, $M = 689.75 \text{ g mol}^{-1}$. IR: $\nu = 1406 (\nu_{\text{C-N}}) \text{ cm}^{-1}$. ^1H NMR (300 MHz, CDCl_3 , δ (ppm)): 6.91 (s, 2H, $\text{CH}_2\text{C}_6\text{H}_3(\text{CH}_3)_2$ -3,5); 6.83 (s, 2H, $\text{C}_6\text{H}_2(\text{CH}_3)_2$ -5,6); 6.68 (s, 4H, $\text{CH}_2\text{C}_6\text{H}_3(\text{CH}_3)_2$ -3,5); 6.59 (d, 2H, *p*- $\text{CH}_3\text{C}_6\text{H}_4\text{-CH}(\text{CH}_3)_2$); 5.54 (d, 2H, *p*- $\text{CH}_3\text{C}_6\text{H}_4\text{CH}(\text{CH}_3)_2$); 5.29 (d, 2H, $\text{H}_{1'}$, CH_2); 5.05 (d, 2H, $\text{H}_{1''}$, CH_2); 2.62 (m, 1H, $\text{H}_{7'''}$, *p*- $\text{CH}_3\text{C}_6\text{H}_4\text{-CH}(\text{CH}_3)_2$); 2.30 (s, 12H, $\text{H}_{\text{c,d,e,f}}$, 4 \times CH_3); 2.21 (s, 6H, $\text{H}_{\text{a,b}}$, 2 \times CH_3); 1.80 (s, 3H, H_{g} , CH_3); 1.14 (s, 6H, $\text{H}_{\text{h,i}}$, 2 \times CH_3) [*p*- $\text{CH}_3\text{-C}_6\text{H}_4\text{CH}(\text{CH}_3)_2$]. ^{13}C NMR (CDCl_3 , 75 MHz) (δ (ppm)): 188.8 (C_2 ,

(NCN); 138.4; 138.2; 134.4; 132.3; 128.9; 123.5; 111.8; 107.3; 96.6; 84.9; 52.3 ($C_{1',1''}$, $2 \times CH_2$); 30.6 ($C_{7'''}$, p -CH₃C₆H₄CH(CH₃)₂); 22.6 ($C_{a,b}$, $2 \times CH_3$, C₆H₂(CH₃)₂-5,6); 21.6 ($C_{c,d,e,f}$, $4 \times CH_3$); 20.3 ($C_{h,i}$, $2 \times CH_3$); 18.0 (C_g , CH₃).

DART-TOF-MS: $m/z = 279$, 343.

5.4. Dichloro-[1,3-bis(4-methylbenzyl)benzimidazol-2-ylidene](*p*-cymene)-ruthenium(II), 3b

Yield: (90%); mp 210 °C. C₃₅H₄₁Cl₂N₂Ru, $M = 733.85$ g mol⁻¹. IR: $\nu = 1409$ (ν_{C-N}) cm⁻¹. ¹H NMR (300 MHz, CDCl₃, δ (ppm)): 0.14 (d, 4H, CH₂C₆H₄(CH₃)₄); 7.00 (d, 4H, CH₂C₆H₄(CH₃)₄); 6.79 (s, 2H, C₆H₂(CH₃)₂-5,6); 6.46 (d, 2H, p -CH₃C₆H₄CH(CH₃)₂); 5.68 (d, 2H, p -CH₃C₆H₄CH(CH₃)₂); 5.29 (s, 2H, H_{1'}, CH₂); 5.03 (s, 2H, H_{1''}, CH₂); 2.68 (p, 1H, H_{7'''}, p -CH₃C₆H₄CH(CH₃)₂); 2.34 (s, 6H, H_{c,d}, $2 \times CH_3$); 2.18 (s, 6H, H_{a,b}, $2 \times CH_3$); 1.84 (s, 3H, H_e, CH₃); 1.16 (d, 6H, H_{f,g}, $2 \times CH_3$) (p -CH₃C₆H₄CH(CH₃)₂). ¹³C NMR (CDCl₃, 75 MHz) (δ (ppm)): 189.0 (C₂, NCN); 137.0; 134.9; 134.4; 132.3; 129.6; 125.9; 111.9; 107.6; 97.0; 85.30; 52.5 ($C_{1',1''}$, $2 \times CH_2$); 30.6 ($C_{7'''}$, p -CH₃C₆H₄CH(CH₃)₂); 22.6 ($C_{f,g}$, $2 \times CH_3$); 21.2 ($C_{c,d}$, $2 \times CH_3$); 20.3 (C_e , CH₃); 18.3 ($C_{a,b}$, $2 \times CH_3$); 14.2 (C_h , CH₃).

5.5. Dichloro-[1,3-bis(4-*tert*butylbenzyl)benzimidazol-2-ylidene](*p*-cymene)-ruthenium(II), 3c

Yield: (87%); mp 224 °C. C₄₀H₅₃Cl₂N₂Ru, $M = 733.85$ g mol⁻¹. IR: $\nu = 1609$ (ν_{C-N}) cm⁻¹. ¹H NMR (300 MHz, CDCl₃, δ (ppm)): 7.36 (d, 4H, CH₂C₆H₄C(CH₃)₃₋₄); 7.03 (d, 4H, CH₂C₆H₄C(CH₃)₃₋₄); 6.82 (s, 2H, C₆H₂(CH₃)₂-5,6); 6.55 (d, 2H, p -CH₃C₆H₄CH(CH₃)₂); 5.62 (d, 2H, p -CH₃C₆H₄CH(CH₃)₂); 5.31 (s, 2H, H_{1'}, CH₂); 5.02 (s, 2H, H_{1''}, CH₂); 2.61 (s, 6H, H_{d,g}, $2 \times CH_3$); 2.19 (s, 6H, H_{a,b}, $2 \times CH_3$); 1.81 (s, 3H, H_i, CH₃); 1.66 (s, 1H, H_{7'''}, p -CH₃C₆H₄CH(CH₃)₂); 1.31 (s, 15H, H_{c,e,f,h,i}, $5 \times CH_3); 1.12 (d, 6H, H_{j,k}, $2 \times CH_3$) (p -CH₃C₆H₄CH(CH₃)₂). ¹³C NMR (CDCl₃, 75 MHz) (δ (ppm)): 188.9 (C₂, NCN); 150.4; 134.9; 134.4; 132.3; 125.8; 125.5; 111.9; 106.8; 97.3; 85.5; 52.3 ($C_{1',1''}$, $2 \times CH_2$); 41.1 ($C_{7'''}$, p -CH₃C₆H₄CH(CH₃)₂); 34.6 ($C_{d,g}$, $2 \times CH_3$, CH₂C₆H₄C(CH₃)₃₋₄); 31.4 ($C_{c,e,f,h}$, $4 \times CH_3$); 30.5 (C_i , CH₃); 22.6 ($C_{a,b}$, $2 \times CH_3$); 20.3 ($C_{j,k}$, $2 \times CH_3$). DART-TOF-MS: $m/z = 453$, 426, 291.$

5.6. Dichloro-[1-(3,5-dimethylbenzyl)-3-(2,3,5,6-tetramethylbenzyl)benzimidazol-2-ylidene](*p*-cymene) ruthenium(II), 3d

Yield: (88%); mp 184 °C. C₃₉H₄₉Cl₂N₂Ru, $M = 717.80$ g mol⁻¹. IR: $\nu = 1418$ (ν_{C-N}) cm⁻¹. ¹H NMR (300 MHz, CDCl₃, δ (ppm)): 7.69 (d, 2H, p -CH₃C₆H₄CH(CH₃)₂); 7.54 (d, 2H, p -CH₃C₆H₄CH(CH₃)₂); 7.26 (s, 1H, CH₂C₆H₃(CH₃)_{2-3,5}); 6.89 (s, 2H, CH₂-C₆H₃(CH₃)_{2-3,5}); 6.63 (s, 2H, C₆H₂(CH₃)₂-5,6); 5.88 (s, 1H, CH₂C₆H₄(CH₃)_{4-2,3,5,6}); 4.21 (s, 4H, H_{1',1''}, $2 \times CH_2$); 2.86 (p, 1H, H_{7'''}, p -CH₃C₆H₄CH(CH₃)₂); 2.27 (s, 18H, H_{a,b,c,d,f,g}, $6 \times CH_3$); 2.20 (s, 3H, H_i, CH₃); 1.95 (s, 3H, H_i, CH₃); 1.32 (s, 6H, H_{e,h}, $2 \times CH_3$); 0.92 (s, 6H, H_{j,k}, $2 \times CH_3$) (p -CH₃C₆H₄CH(CH₃)₂). ¹³C NMR (CDCl₃, 75 MHz) (δ (ppm)): 187.8 (C₂, NCN); 138.4; 135.4; 135.2; 134.5; 133.5; 133.2; 132.3; 131.6; 131.3; 130.0; 128.9; 124.6; 123.4; 107.1; 96.2; 54.0 ($C_{1'}$, CH₂); 51.8 ($C_{1''}$, CH₂); 31.0 ($C_{7'''}$, p -CH₃C₆H₄CH(CH₃)₂); 21.5 ($C_{j,k}$, $2 \times CH_3$, p

CH₃C₆H₄CH(CH₃)₂); 20.8 ($C_{c,d}$, $2 \times CH_3$); 20.2 (C_i , CH₃); 18.4 ($C_{f,g}$, $2 \times CH_3$); 16.3 ($C_{a,b}$, $2 \times CH_3$); 15.4 ($C_{e,h,i}$, $3 \times CH_3$).

5.7. Dichloro-[1-(3,5-dimethylbenzyl)-3-(4-*tert*butylbenzyl)benzimidazol-2-ylidene](*p*-cymene) ruthenium(II), 3e

Yield: (86%); mp 222 °C. C₃₉H₄₉Cl₂N₂Ru, $M = 717.80$ g mol⁻¹. IR: $\nu = 1404$ (ν_{C-N}) cm⁻¹. ¹H NMR (300 MHz, CDCl₃, δ (ppm)): 7.34 (d, 2H, p -CH₃C₆H₄CH(CH₃)₂); 7.03 (d, 2H, p -CH₃C₆H₄CH(CH₃)₂); 6.92 (s, 1H, CH₂C₆H₃(CH₃)_{2-3,5}); 6.84 (s, 4H, CH₂-C₆H₃(CH₃)_{2-3,5}); 6.68 (s, 2H, CH₂C₆H₄C(CH₃)₃₋₄); 6.54 (s, 2H, CH₂C₆H₃(CH₃)_{2-3,5}); 5.58 (s, 2H, C₆H₂(CH₃)₂-5,6); 5.30 (s, 2H, H_{1'}, CH₂); 5.01 (s, 2H, H_{1''}, CH₂); 2.58 (p, 1H, H_{7'''}, p -CH₃C₆H₄CH(CH₃)₂); 2.30 (s, 6H, H_{c,d}, $2 \times CH_3$); 2.20 (s, 6H, H_{a,b}, $2 \times CH_3$); 1.81 (s, 3H, H_f, CH₃); 1.57 (s, 3H, H_h, CH₃); 1.31 (s, 6H, H_{i,j}, $2 \times CH_3$) (p -CH₃C₆H₄CH(CH₃)₂); 1.12 (s, 6H, H_{e,g}, $2 \times CH_3). ¹³C NMR (CDCl₃, 75 MHz) (δ (ppm)): 189.1 (C₂, NCN); 150.4; 138.4; 138.2; 135.0; 134.4; 132.3; 129.0; 127.7; 125.7; 125.6; 123.6; 111.9; 107.1; 97.0; 85.2; 52.3 ($C_{1'}$, CH₂); 52.2 ($C_{1''}$, CH₂); 34.6 ($C_{7'''}$, p -CH₃C₆H₄CH(CH₃)₂); 31.4 ($C_{c,d}$, $2 \times CH_3$, p -CH₃C₆H₄CH(CH₃)₂); 30.5 ($C_{a,b}$, $2 \times CH_3$); 22.7 (C_f , CH₃); 21.6 ($C_{i,j}$, $2 \times CH_3$); 20.3 (C_h , CH₃); 18.1 ($C_{e,g}$, $2 \times CH_3$).$

5.8. Dichloro-[1-(3,5-dimethylbenzyl)-3-(4-methylbenzyl)benzimidazol-2-ylidene](*p*-cymene) ruthenium(II), 3f

Yield: (80%); mp 204 °C. C₃₆H₄₃Cl₂N₂Ru, $M = 675.73$ g mol⁻¹. IR: $\nu = 1404$ (ν_{C-N}) cm⁻¹. ¹H NMR (300 MHz, CDCl₃, δ (ppm)): 7.13 (d, 2H, p -CH₃C₆H₄CH(CH₃)₂); 7.00 (d, 2H, p -CH₃C₆H₄CH(CH₃)₂); 6.92 (s, 1H, CH₂C₆H₃(CH₃)_{2-3,5}); 6.84 (d, 4H, CH₂-C₆H₄(CH₃)₄); 6.67 (s, 2H, CH₂C₆H₃(CH₃)_{2-3,5}); 6.51 (m, 2H, CH₂C₆H₄(CH₃)₄); 5.57 (m, 2H, C₆H₂(CH₃)₂-5,6); 5.30 (s, 2H, H_{1'}, CH₂); 5.02 (s, 2H, H_{1''}, CH₂); 2.64 (p, 1H, H_{7'''}, p -CH₃C₆H₄CH(CH₃)₂); 2.34 (s, 3H, H_e, CH₃); 2.30 (s, 6H, H_{c,d}, $2 \times CH_3$); 2.19 (s, 6H, H_{a,b}, $2 \times CH_3$); 1.82 (s, 3H, H_f, CH₃); 1.58 (s, 3H, H_i, CH₃); 1.15 (s, 6H, H_{g,h}, $2 \times CH_3$) (p -CH₃C₆H₄CH(CH₃)₂). ¹³C NMR (CDCl₃, 75 MHz) (δ (ppm)): 189.2 (C₂, NCN); 138.4; 138.2; 137.0; 135.0; 134.5; 134.3; 132.3; 129.6; 129.0; 125.8; 123.6; 111.9; 107.4; 96.6; 85.2; 52.4 ($C_{1'}$, CH₂); 52.2 ($C_{1''}$, CH₂); 30.6 ($C_{7'''}$, p -CH₃C₆H₄CH(CH₃)₂); 21.6 ($C_{h,g}$, $2 \times CH_3$, p -CH₃C₆H₄CH(CH₃)₂); 21.2 ($C_{c,d}$, $2 \times CH_3$); 22.3 ($C_{e,f}$, $2 \times CH_3$); 18.1 ($C_{a,b,i}$, $3 \times CH_3$).

5.9. Antibacterial activity

5.9.1. Bacterial strains, media and growth conditions.

Bacteria strains used as indicator microorganisms for the antibacterial activity assays were: *Micrococcus luteus* (*M. luteus*) LB 14110, *Staphylococcus aureus* (*S. aureus*) ATCC6538, *Listeria monocytogenes* (*L. monocytogenes*) ATCC 19117, *Salmonella typhimurium* (*S. typhimurium*) ATCC 14028, *Pseudomonas aeruginosa* (*P. aeruginosa*) ATCC 49189 and *E. coli* were obtained from International Culture Collections (ATCC) and local culture collection of the Laboratory of Microorganisms and Biomolecules of the Centre of Biotechnology of Sfax-Tunisia.

These bacterial strains were grown overnight in Luria-Bertani (LB) agar medium (g l⁻¹): peptone 10; yeast extract 5 and NaCl 5 at pH 7.2 under aerobic conditions and constant agitation (200 rpm) at 30 °C for *M. luteus* LB14110 and *L. monocytogenes* ATCC 19117 and at 37 °C for *S. aureus* ATCC 6538, *S.*

typhimurium ATCC 14028 and *P. aeruginosa* ATCC49189, and then diluted 1 : 100 in LB media and incubated for 5 h under constant agitation (200 rpm) at the appropriate temperature.

5.9.2. Agar well diffusion method. Agar well diffusion method was employed for the determination of the antimicrobials activity of the synthesized compounds according to Güven *et al.* (2006) with some modifications. Briefly, the synthesized compounds are allowed to diffuse out into the appropriate agar medium (LB agar medium) and interact in a plate freshly seeded with a suspension of the indicators microorganisms (0.1 ml of 10^8 cells per ml). The plate was incubated at the appropriate temperature after staying at 4 °C for 2 h. The resulting zones of inhibition will be uniformly circular as there will be a confluent lawn of growth. The antibacterial activity was assayed by measuring in millimeters the diameter of the inhibition zone formed around the well. All tests are assayed in triplicate and expressed as the average \pm standard deviation of the measurements.

5.9.3. Minimum inhibitory concentration (MIC). The minimum inhibitory concentration (MIC) of the synthesized compounds was determined in accordance with NCCLS guideline M7-A6 and M38-P (National Committee for clinical laboratory standard, Wayne 1998). The test was performed in sterile 96-well microplates with a final volume in each microplate well of 100 μ l. The synthesized compounds (20 mg ml⁻¹) were properly prepared in solution of dimethylsulfoxide (DMSO)/water (1/9; v/v). The inhibitory activity of each synthesized compound was transferred to each well in order to obtain a twofold serial dilution of the original sample and visible growth after incubation. As an indicator of microorganism growth, 25 μ l of Thiazolyl Blue Tetrazolium Bromide (MTT), indicator solution (0.5 mg ml⁻¹) dissolved in sterile water were added to the wells and incubated at room temperature for 30 min. This determination was done in triplicate and obtained results were very similar. The reported value is the average of the three tests.

5.9.4. Antioxidant activity: DPPH radical scavenging activity. Scavenging of 2,2-diphenyl-1-picrylhydrazyl radical (DPPH \cdot assay) is the simplest and most widely reported method for screening antioxidant activity. The procedure involves measurement of decrease in absorbance of DPPH at its absorption maxima of 517 nm. This assay determines the scavenging of stable radical species according to the method of Kirby and Schmidt, (1997) with slight modifications. Briefly, synthesized compounds were dissolved in dimethylsulfoxide (DMSO)/water (1/9; v/v) and diluted with ultrapure water at different concentrations (1, 0.5, 0.250, 0.125, 0.0625, 0.03125 mg ml⁻¹). Then, 500 μ l of a 4% (w/v) solution of DPPH radical in ethanol was mixed with 500 μ l of samples. The mixture was incubated for 30 min in the dark at room temperature. The scavenging capacity was determined spectrophotometrically by monitoring the decrease in absorbance at 517 nm against a blank. The percentage of antiradical activity (% ArA) had been calculated as follows:

$$\% \text{ ArA} = \frac{(\text{absorbance of control} - \text{absorbance of test sample})}{\text{absorbance of control}} \times 100.$$

All tests are assayed in triplicate and expressed as the average \pm standard deviation of the measurements to produce the concentration range of 0.0048–20 mg ml⁻¹. To each test well 10 μ l of cell suspension were added to final inoculum concentrations of 106 CFU ml⁻¹ for each microorganisms. Positive growth control wells consisted of microorganisms only in their adequate medium. Cells suspension at the same concentration supplemented with ampicillin was used as control. The plates were then covered with the sterile plate covers and incubated at the appropriate temperature of each microorganism. The MIC was defined as the lowest concentration of the synthesized compound at which the microorganism does not demonstrate.

5.9.5. Antioxidant activity: ABTS radical scavenging activity. This manipulation was carried out according to the protocol proposed by Re *et al.* (1999) with some modifications,¹⁴ 20 μ l of extract were mixed with 18 μ l of ABTS^{•+} solution, the whole was mixed vigorously for 30 s. A control consisting of ethanol and ultrapure water was prepared (5 : 5) v/v to which the previous solution was added. White is ethanol and ultrapure water (5 : 5) v/v. Samples and control were incubated for 6 min in the dark, then the OD was measured at 734 nm. Gallic acid, ascorbic acid and BHT were used as standards the calculation is done according to the following formula:

$$\text{AAOx}\% = [(A_c - A_s)/A_c] \times 100$$

A_c : absorbance of the control, A_s : absorbance of the sample.

5.10. Antifungal activity

5.10.1. Assessment, yeast strain and growth conditions. The choice of fungal strains is an important step in the antifungal screening study; it should be focused first on sensitive reference strains. This prompted us to carry out tests on multidrug-resistant yeast of *Candida albicans*.

Antifungal activity was evaluated against *Candida albicans*. This strain is a species of yeast. The evaluation of the activity of the compounds synthesized with respect to the strain of *C. albicans* was carried out using the diffusion method on a solid medium.

C. albicans is cultivated in a YPD medium whose composition is as follows: 10 g of yeast extract; 20 g peptone; 20 g glucose (or dextrose); H₂O qsp 1 L; pH = 5.6.

5.10.2. Agar well diffusion method. For the determination of the antifungal activity, the yeast has been cultivated:

In solid medium: *C. albicans* is cultivated in Sabouraud medium and incubated for 48 h at 30 °C.

In liquid medium: *C. albicans* is cultivated in YPD medium in Erlenmeyer flasks. The cultures are incubated at 30 °C for 48 h with constant stirring at 250 rpm. For preservation, 200 μ l of each culture is mixed with 800 μ l of glycerol in cryotubes and stored at –80 °C.

5.10.3. Acetylcholinesterase inhibitory potential (AChEI). AChE inhibitory activity was measured by slightly modified spectrophotometric method of Ellman *et al.* (1961). Electric eel AChE was used, while acetylthiocholine iodide (ATCI) was employed as substrate of the reaction. 5,5'-Dithiobis(2-

nitrobenzoic acid) (DTNB) was used for the measurement of the antiacetylcholinesterase activity. Briefly, in this method, 100 μ l of Tris buffer at 50 mM (pH 8.0), 30 μ l of sample or standard and 5 μ l of AChE enzyme (0.5 U ml^{-1}) were added in a 96 well microplate and incubated for 10 min at 25 $^{\circ}\text{C}$. Then, 142 μ l of DTNB (3 mM) and 23 μ l of substrate (75 mM) were added. Hydrolysis of ATCI was monitored by the formation of the yellow 5-thio-2-nitrobenzoate anion as a result of the reaction of DTNB with thiocholines, catalyzed by enzymes at 405 nm utilizing a 96 well microplates reader (Thermo Scientific/Varioskan Flash, Germany). The kinetic reaction has been followed until the AChE activity decreased, and then the reaction has been stopped. Percentage of inhibition of AChE was determined by comparison of rates reaction of samples relative to control (10% DMSO in Tris buffer) using the following formula:

$$\% \text{ AChEI} = 1 - (\delta A_{\text{sample}} / \delta A_{\text{control}}) \times 100$$

where δA_{sample} : sample absorbance at zero time – sample absorbance at the end of reaction, and $\delta A_{\text{control}}$: control absorbance at zero time – control absorbance at the end of reaction. Galanthamine was used as standard.

All synthesised compounds have been tested at 100 $\mu\text{g ml}^{-1}$ of concentration. This determination was done in triplicate and obtained results were very similar. The reported value is the average of the three tests.

Conflicts of interest

There are no conflicts to declare.
