# A single-phase white light emitting phosphor Ba<sub>3</sub>Y(PO<sub>4</sub>)<sub>3</sub>:Ce<sup>3+</sup>/Tb<sup>3+</sup>/Mn<sup>2+</sup>: luminescence, energy transfer and thermal stability

Yun Chen, Wenge Ding,\* Panlai Li, D\* Xue Li, Qi Bao, Jinjin Liu, Keliang Qiu, Xiangyu Meng, Zhiping Yang and Zhijun Wang p\*

A series of  $Ce^{3+}/Tb^{3+}$ ,  $Tb^{3+}/Mn^{2+}$  and  $Ce^{3+}/Tb^{3+}/Mn^{2+}$  doped  $Ba_{7}Y(PO_{4})_{7}$  were synthesized by the high temperature solid state method. Phase formation, energy transfer, luminescence properties and thermal quenching properties of phosphors were analyzed in detail. For the co-doped samples, the energy transfer from  $Ce^{3+}$  to  $Tb^{3+}$  and  $Tb^{3+}$  to  $Mn^{2+}$  was proved by analyzing the spectra and fluorescence lifetime, and the energy transfer mechanism was calculated to be dipole-dipole interaction. A series of color-tunable phosphors were obtained by the energy transfer from Ce<sup>3+</sup> to Tb<sup>3+</sup> and Tb<sup>3+</sup> to Mn<sup>2+</sup>. For the tri-doped samples, it was confirmed that the energy transfers from Ce<sup>3+</sup> to Tb<sup>3+</sup>, Tb<sup>3+</sup> to Mn<sup>2+</sup> and Ce<sup>3+</sup> to Mn<sup>2+</sup> exist at the same time by analyzing the spectra properties, and it can emit warm-white light with extensive color temperature regulability. In addition, the thermal stability was abnormal and outstanding because the defects exist in the samples. The results show that the phosphors may be novel warm white emitting phosphors for white light emitting diodes.

### Introduction

In recent years, white-light-emitting diodes (LEDs) have received more and more attention for their many advantages1 Compared with traditional light sources, white LEDs have higher efficiency, higher brightness, longer service time and are more environmentally friendly, hence they are considered as the fourth generation light source.1-7 The most common method to synthesize white LEDs is to combine the GaN blue LED chip with yellow phosphor YAG:Ce<sup>3+</sup>. However, this type of white LED has many drawbacks due to lack of a red ingredient, such as the poor color rendering index and the high correlated color temperature.3,4,8 Because white LEDs can not only be used in lighting field, but also in display and medical fields, hence they should show specific optical performance in different application scenarios which means that phosphors with high tunability are needed.7,9 Nowadays, the ultraviolet-excited single-phased phosphors have been taken seriously, which can achieve white light with good color rendering index, suitable correlated color temperature and tunable emission by adjusting the doping ratio of different ions. 10-13 Therefore, it is urgent to find novel and high performance single-phased phosphors. Generally, when doping rare earth ions or transition metal ions into compound, the white emitting phosphor

National-Local Joint Engineering Laboratory of New Energy Photoelectric Devices, Hebei Key Laboratory of Optic-electronic Information and Materials, College of Physics Science & Technology, Hebei University, Baoding 071002, China. E-mail: dwg@hbu.edu.cn; li\_panlai@126.com; wangzj1998@126.com

may be achieved by the energy transfer between different activator ions, 4 such as Ca<sub>10</sub>Na(PO<sub>4</sub>)<sub>7</sub>:Ce<sup>3+</sup>/Tb<sup>3+</sup>/Mn<sup>2+</sup>, 5 Na<sub>2</sub>Ba<sub>6</sub>(- $Si_2O_7$ )( $SiO_4$ )<sub>2</sub>: $Ce^{3+}/Eu^{2+}/Tb^{3+}/Mn^{2+}$ . Among many host compounds, the eulytite-type orthophosphates with the type of  $M_3^I M^{II} (PO_4)_3 (M^I = Ba, Sr, Ca, and Pb, M^{II} = La, Sc, Y, Bi, and In)$ have attracted great interests, for example, when doped Ce<sup>3+</sup>, Tb<sup>3+</sup>, and Mn<sup>2+</sup> in Ba<sub>3</sub>Y(PO<sub>4</sub>)<sub>3</sub> (BYP), the phosphors can produce blue, green and red light, respectively. 17-19 Thus, it is possible to achieve white emission when the above three ions are tri-doped in BYP. Moreover, the thermal stability of phosphor is an essential characteristic. It has been reported in our previous work that BYP:Ce<sup>3+</sup>,Mn<sup>2+</sup> shows extraordinary thermal stability due to the existence of defect in the samples. 17 It is expectable that the defect is to be utilized to gain a series of phosphors with high temperature stability in Ce<sup>3+</sup>/Tb<sup>3+</sup>/Mn<sup>2+</sup> doped BYP. In this work, series of Ce<sup>3+</sup>/Tb<sup>3+</sup>, Tb<sup>3+</sup>/Mn<sup>2+</sup> or Ce<sup>3+</sup>/Tb<sup>3+</sup>/Mn<sup>2+</sup> doped BYP are obtained. Phase formation, energy transfer, luminescence properties and thermal property were investigated in detail. Finally, series of single-phased white emitting phosphors are obtained by the energy transfer  $Ce^{3+} \rightarrow Tb^{3+}$ ,  $Tb^{3+} \rightarrow Mn^{2+}$ and  $Ce^{3+} \rightarrow Mn^{2+}$ .

#### 2 **Experimental**

#### Sample preparation 2.1

 $Ba_3Y_{0.95-x}(PO_4)_3:0.05Ce^{3+},xTb^{3+}$ Series  $Ba_{3-y}Y_{0.95}(PO_4)_3:0.05Ce^{3+},yMn^{2+}$  $Ba_{2.86}Y_{0.7-z}(PO_4)_3$ :2 $Ce^{3+}$ ,0.3 $Tb^{3+}$ ,0.14 $Mn^{2+}$  were synthesized by a high temperature solid state method. Raw materials BaCO<sub>3</sub>

(analytical reagents, A.R.), NH<sub>4</sub>H<sub>2</sub>(PO<sub>4</sub>)<sub>3</sub> (A.R.), Y<sub>2</sub>O<sub>3</sub> (99.99%),  $CeO_2$  (99.99%),  $Tb_4O_7$  (99.99%) and  $MnCO_3$  (A.R.) were weighed according to stoichiometric proportions, and then mixed them in an agate mortar pestling for 20 min to ensure the materials are distributed uniformly. The mixed materials were put into crucibles and heated at 1300 °C for 3 h in a carbon reducing atmosphere. After firing, the samples cooled to room temperature slowly and were grounded into powder for subsequent use.

#### 2.2 Materials characterization

XRD patterns of sample are measured by powder X-ray diffraction (XRD) using a D8-A25 Focus diffractometer at 40 kV and 40 mA with step size of 0.05° and a scan speed 0.1 s per step. Spectral property of sample was measured by Hitachi F-4600 fluorescence spectrophotometer with a 450 W Xe lamp as the excitation source. Decay curves were measured by Horiba FL-4600 fluorescence spectrophotometer with a 320 nm pulse laser radiation (nano-LED) for Ce<sup>3+</sup> and 450 W Xe lamp as the excitation resource for Mn<sup>2+</sup> at room temperature. Thermoluminescence spectra of samples were measured by a FJ-427A1 TL dosimeter at room temperature with a fixed heating rate of 1 k s<sup>-1</sup> within the range 300–450 K. Commission Internationale de L'Eclairage (CIE) chromaticity coordinates of samples were obtained by the PMS-80 spectral analysis system.

## Results and discussion

#### 3.1 Phase formation

The XRD patterns of BYP: $0.05Ce^{3+}$ , $xTb^{3+}$  (x = 0.02, 0.45), BYP:0.05Ce3+,yMn2+ (v = 0.08, BYP: $zCe^{3+}$ , 0.3Tb<sup>3+</sup>, 0.14Mn<sup>2+</sup> (z = 0.07, 0.15) were shown in Fig. 1. It can be seen that no apparent impurity phase appears and all the diffraction peaks of samples can be indexed to the standard card of BYP (JCPDS No. 44-0318) appropriately. The XRD patterns illustrates that Ce<sup>3+</sup>, Tb<sup>3+</sup> and Mn<sup>2+</sup> did not cause any significant change to the crystal structure of BYP and series of pure phase phosphors were obtained.

#### 3.2 Luminescence and energy transfer properties of BYP:Ce<sup>3+</sup>.xTb<sup>3+</sup>

Fig. 2a-c display the emission and excitation spectra of BYP:0.05Ce<sup>3+</sup> ( $\lambda_{ex} = 330 \text{ nm}, \lambda_{em} = 400 \text{ nm}$ ), BYP:0.45Tb<sup>3+</sup> ( $\lambda_{ex} =$ 377 nm,  $\lambda_{\rm em} = 550$  nm) and BYP:0.05Ce<sup>3+</sup>,0.15Tb<sup>3+</sup> ( $\lambda_{\rm ex} =$ 330 nm,  $\lambda_{em} = 400$  nm, 550 nm), respectively. The emission spectrum of BYP:0.05Ce<sup>3+</sup> shows a blue emission band peaking at 400 nm, which originates from the electron transition 5d  $\rightarrow$ 4f of Ce<sup>3+</sup>. The excitation band of BYP:0.05Ce<sup>3+</sup> ranges from 200 nm to 360 nm ( $\lambda_{max} = 330$  nm) due to the 4f  $\rightarrow$  5d electron transition. For BYP:0.45Tb<sup>3+</sup>, a series of characteristic emission peaks of Tb<sup>3+</sup> appear in the emission spectrum which originates from the electron transition  ${}^5D_4 \rightarrow {}^7F_6$  (500 nm),  ${}^5D_4 \rightarrow {}^7F_5$  (550 nm),  ${}^5D_4 \rightarrow {}^7F_4$  (590 nm) and  ${}^5D_4 \rightarrow {}^7F_3$  (630 nm) of Tb<sup>3+</sup>, respectively. The excitation spectrum of BYP:0.45Tb3+ shows a broad excitation band from 210 nm to 400 nm because of the allowed 4f<sup>8</sup>-4f<sup>7</sup>5d transition and intra-configuration transition of Tb<sup>3+</sup>. Comparing the emission spectrum of BYP:0.05Ce<sup>3+</sup>

with the excitation spectrum of BYP:0.45Tb<sup>3+</sup>, an obvious spectral overlapping can be observed which means an effective energy transfer from Ce<sup>3+</sup> to Tb<sup>3+</sup> (ET<sub>Ce-Tb</sub>) may be occur. 19,20 In addition, the emission spectrum of BYP:0.05Ce3+,0.15Tb3+ contains both the emission band of Ce<sup>3+</sup> and Tb<sup>3+</sup>, the excitation spectrum monitored at 550 nm (emission peak of Tb<sup>3+</sup>) has the similar profile with that monitored at 400 nm (emission peak of Ce<sup>3+</sup>), it also means that there may be energy transfer from Ce<sup>3+</sup> to Tb<sup>3+</sup>.

In order to further investigate the luminescence properties, a series of BYP:Ce<sup>3+</sup>,xTb<sup>3+</sup> were synthesized. Fig. 3a shows the emission spectra of BYP:0.05Ce<sup>3+</sup>,xTb<sup>3+</sup> (x = 0-0.45) under 330 nm UV excitation. Fig. 3b reveals the emission intensity of  $\mathrm{Ce^{3+}}$  ( $\lambda_{\mathrm{em}}$  = 400 nm) and  $\mathrm{Tb^{3+}}$  ( $\lambda_{\mathrm{em}}$  = 550 nm), it can be seen that the emission intensity of Ce<sup>3+</sup> declines constantly as the concentration of Tb<sup>3+</sup> increasing, meanwhile, the emission intensity of Tb3+ goes up ceaselessly. According to the change of emission intensity, it means that an effective energy transfer from Ce<sup>3+</sup> to Tb<sup>3+</sup> is expectable.

To confirm the energy transfer from Ce<sup>3+</sup> to Tb<sup>3+</sup>, the decay curves of Ce3+ monitored at 400 nm under 320 nm pulse laser radiation (nano-LED) excitation and decay curves of Tb3+ monitored at 550 nm under 377 nm excitation for BYP:0.05Ce<sup>3+</sup>,xTb<sup>3+</sup> are shown in Fig. 4a and b, respectively. The decay curves of Ce<sup>3+</sup> and Eu<sup>2+</sup> can be matched well with secondorder exponential function, which can be expressed as the following expression:21,22

$$I_{(t)} = A_1 \exp(t/\tau_1) + A_2 \exp(t/\tau_2)$$
 (1)

where  $I_{(t)}$  is the luminescence intensity,  $A_1$  and  $A_2$  are constants, t is time,  $\tau_1$  and  $\tau_2$  are the lifetimes for the exponential components. The average lifetime  $\tau^*$  can be calculated by the following formula21,23

$$\tau^* = (A_1 \tau_1^2 + A_2 \tau_2^2) / (A_1 \tau_1 + A_2 \tau_2)$$
 (2)

The calculated average lifetime of Ce<sup>3+</sup> and Tb<sup>3+</sup> are shown in Fig. 4c, from which one can see that the lifetime of Ce3+ decreases consistently and that of Tb3+ increases consistently with increasing Tb3+ concentration. The lifetime can strongly prove the energy transfer from Ce<sup>3+</sup> to Tb<sup>3+</sup>, and the energy transfer efficiency can be calculated by the following equation9,22

$$\eta_{\rm T} = 1 - \tau/\tau_0 \tag{3}$$

where  $\tau$  and  $\tau_0$  are the decay time of the sensitizer Ce<sup>3+</sup> in the presence and absence of activator Tb3+, respectively. Fig. 4d shows that the energy transfer efficiency rises up constantly with increase Tb3+ concentration, and the maximum value is 69.9% when the doping concentration of Tb3+ reaches the maximum x = 0.45.

According to Dexter's theory, there are two types of interactions between sensitizers and activators: multipolar interaction and exchange interaction.<sup>21,24</sup> The critical distance between Ce<sup>3+</sup> and  $Tb^{3+}$  ( $R_{Ce-Tb}$ ) is a critical factor to judge which type it

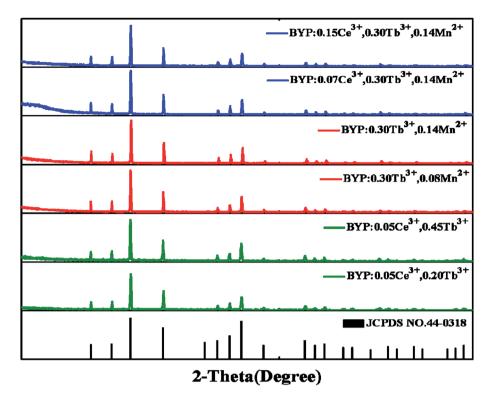

Fig. 1 XRD patterns of the representative samples and the standard patterns of Ba<sub>3</sub>Y(PO<sub>4</sub>)<sub>3</sub> (JCPDS No. 44-0318).

belongs to, and the critical distance  $R_{\text{Ce-Tb}}$  can be calculated by the following formula<sup>25</sup>

$$R_{\rm c} = 2 \left[ \frac{3V}{4N\pi\chi_{\rm c}} \right]^{\frac{1}{3}} \tag{4}$$

where N is the number of the cations in host, V is the volume of the unit cell.  $\chi_c$  is the sum of  $Ce^{3+}$  and  $Tb^{3+}$  concentration when the emission intensity of  $Ce^{3+}$  in the presence of  $Tb^{3+}$  is half that in the absence of  $Tb^{3+}$ . Herein, V equals to 1165.61 Å<sup>3</sup> and V equals to 4, V is calculated to be 0.2. Thus, the V is calculated to be 17.72 Å which is larger than the maximum distance of 5 Å for the exchange interaction, it means the energy

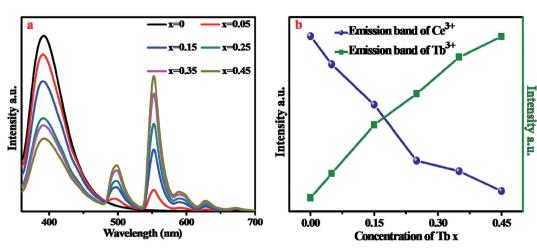

Fig. 3 (a) Emission spectra of BYP:0.05Ce $^{3+}$ ,xTb $^{3+}$  (x = 0-0.45). (b) Emission intensity of Ce $^{3+}$  and Tb $^{3+}$  as a function of Tb $^{3+}$  concentration.

transfer mechanism of Ce<sup>3+</sup>-Tb<sup>3+</sup> belongs to multipolar interaction.

There are three kinds of multipolar interactions: dipole-dipole, dipole-quadrupole and quadrupole-quadrupole interaction. The mechanism of  $ET_{Ce-Tb}$  can be discussed by Dexter's theory:<sup>24,26</sup>

$$\frac{I_{s0}}{I_s} \propto C^{\frac{n}{3}} \tag{5}$$

where  $I_{s0}$  and  $I_s$  are the emission intensity of sensitizer Ce<sup>3+</sup> in the absence and presence of the activator Tb<sup>3+</sup>, respectively. The sum concentration of Ce<sup>3+</sup> and Tb<sup>3+</sup> is represented by *C*. Herein, n = 6, 8 and 10 correspond to dipole–dipole, dipole–quadrupole

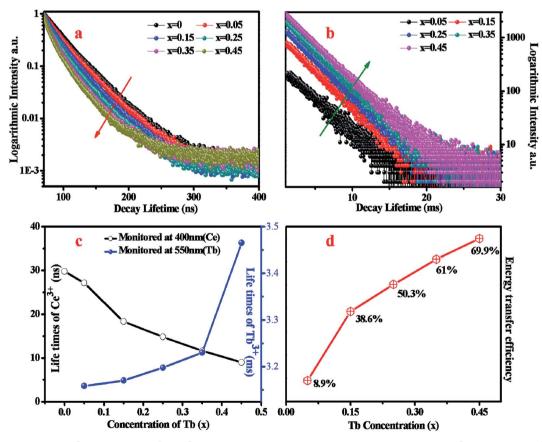

Fig. 4 (a) Decay curves of  $Ce^{3+}$  in BYP:0.05 $Ce^{3+}$ , $xTb^{3+}$  ( $\lambda_{em}=400$  nm,  $\lambda_{ex}=320$  nm). (b) Decay curves of  $Tb^{3+}$  in BYP:0.05 $Ce^{3+}$ , $xTb^{3+}$  ( $\lambda_{em}=550$  nm,  $\lambda_{ex}=377$  nm). (c) Lifetime of  $Ce^{3+}$  and  $Tb^{3+}$  as function of  $Tb^{3+}$  concentration. (d) Energy transfer efficiency from  $Ce^{3+}$  to  $Tb^{3+}$  as function of  $Tb^{3+}$  concentration.

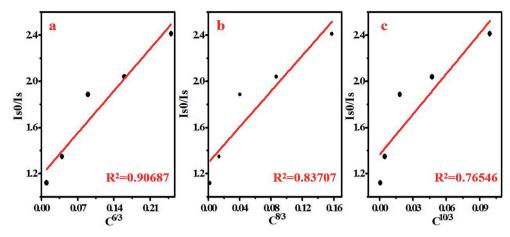

Fig. 5 Dependence of  $I_{s0}/I_{s}$  of  $Ce^{3+}$  and  $Tb^{3+}$  on  $C^{6/3}$ ,  $C^{8/3}$  and  $C^{10/3}$  in BYP:0.05Ce<sup>3+</sup>, $xTb^{3+}$ .

and quadrupole–quadrupole interactions, respectively.  $^{24,26,27}$  The linear relationship between  $I_{s0}/I_s$  and  $C^{n/3}$  for BYP:0.05Ce $^{3+}$ ,xTb $^{3+}$  are illustrated in Fig. 5, it can be seen that a well fitted curve can be gotten when n=6 ( $R^2=0.94952$ ), hence it can be concluded that the dipole–dipole interaction plays an essential role in the energy transfer from Ce $^{3+}$  to Tb $^{3+}$ .

The Commission Internationale de L'Eclairage (CIE) chromaticity coordinates of BYP:0.05Ce<sup>3+</sup>,xTb<sup>3+</sup> (x = 0-0.45) was calculated basing on the relevant emission spectra under 330 nm excitation. The results along with luminescent photographs of related phosphors are depicted in Fig. 6, the emission color of BYP:0.05Ce<sup>3+</sup>,xTb<sup>3+</sup> can be modulated from blue (0.1622, 0.0406) to yellow-green (0.2946, 0.4169). Hence, series of color-tunable phosphors were synthesized successfully.

To analyze the thermal stability of BYP:0.05Ce<sup>3+</sup>,*x*Tb<sup>3+</sup>, the temperature-dependent emission spectra of BYP:0.05Ce<sup>3+</sup>,0.45Tb<sup>3+</sup> excited by 330 nm were measured which is shown in Fig. 7a, and the emission intensity of Ce<sup>3+</sup> and Tb<sup>3+</sup>

with increasing the temperature is depicted in Fig. 7b. It can be seen from the pictures that the emission intensity of Ce<sup>3+</sup> shows a first increases and then decreases with increasing the temperature, but it remains 107.7% of the initial value (300 K) when the temperature reaches 425 K. As for Tb<sup>3+</sup>, its emission intensity increases constantly and reaches to 138.8% of the initial value when the temperature reaches 425 K. The abnormal change of emission intensity of Ce<sup>3+</sup> and Tb<sup>3+</sup> with temperature may be caused by the defects in BYP:0.05Ce<sup>3+</sup>,0.45Tb<sup>3+</sup>.28-30 Fig. 8a shows the thermoluminescence spectrum of BYP:0.05Ce<sup>3+</sup>,0.45Tb<sup>3+</sup>, it can be seen that there are two emission bands ranging from 400 K to 420 K and from 460 K to 480 K, respectively. The thermoluminescence spectrum confirms the existence of defects. Fig. 8b depicts how defects affect the thermal stability of BYP:0.05Ce<sup>3+</sup>,xTb<sup>3+</sup>: the shallow trap D1 and deep trap D2 can store the electrons, but the electrons transmit to the conduction band when BYP:0.05Ce<sup>3+</sup>,xTb<sup>3+</sup> are heated. After that, a part of electrons transmit to <sup>5</sup>D<sub>4</sub> energy level of Tb<sup>3+</sup> and 5d energy band of Ce3+ from conduction band, then more

#### 3.3 Luminescence and energy transfer of BYP:0.4Tb<sup>3+</sup>,yMn<sup>2+</sup>

The emission spectra of BYP:0.4Tb<sup>3+</sup>,yMn<sup>2+</sup> excited by 377 nm UV-light are shown in Fig. 9a and the relative emission intensities at 550 nm and 600 nm are depicted in Fig. 9b. The emission intensity of Tb3+ (550 nm) decreases constantly with increasing Mn<sup>2+</sup> concentration, it means that Mn<sup>2+</sup> may absorb energy from Tb<sup>3+</sup>. It is worth noting that the emission peaks of Tb3+ and Mn2+ coexist at 600 nm, as increasing Mn2+ concentration the source of the peak at 600 nm change from Tb<sup>3+</sup>  $(^{5}D_{4}-^{7}F_{4})$  to both Mn<sup>2+</sup>  $(^{4}T_{1}-^{6}A_{1})$  and Tb<sup>3+</sup> and Mn<sup>2+</sup> is a main source. The intensity of the peak at 600 nm shows a first decrease, then increase and decrease in the end. The possible energy transfer maybe the main reason for the intensity changing: as increasing Mn<sup>2+</sup> concentration the energy transfer from Tb<sup>3+</sup> to Mn<sup>2+</sup> started to work, thus the emission intensity shows a first decrease; after that, the concentration of Mn<sup>2+</sup> is enough, hence the source of the emission peak mainly originates from Mn<sup>2+</sup> and the emission intensity of Tb<sup>3+</sup> is too low, thus the emission intensity of the peak at 600 nm started to pick up. In the end, the concentration of Mn<sup>2+</sup> reaches the quenching point, so its emission intensity started to decrease again.

To confirm the energy transfer from Tb3+ to Mn2+ in BYP:0.4Tb  $^{3+}$  ,yMn  $^{2+}$  , the decay curves of Tb  $^{3+}$  (  $\lambda_{em}=550$  nm,  $\lambda_{ex}$ = 377 nm) and monitored at 600 nm (including  $Tb^{3+}$  and  $Mn^{2+}$ ,  $\lambda_{\rm ex} = 377$  nm) are shown in Fig. 10a and b, respectively. The decay curves can be matched well with second-order exponential function expression (2), by means of expression (2) the

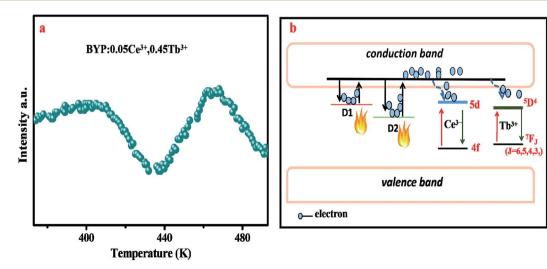

Fig. 8 (a) Thermoluminescence spectrum of BYP:0.05Ce<sup>3+</sup>,0.45Tb<sup>3+</sup>. (b) Schematic diagram of the interaction between the defect and temperature-dependent emission intensity in BYP:0.05Ce<sup>3+</sup>.0.45Tb<sup>3+</sup>.

RSC Advances Paper

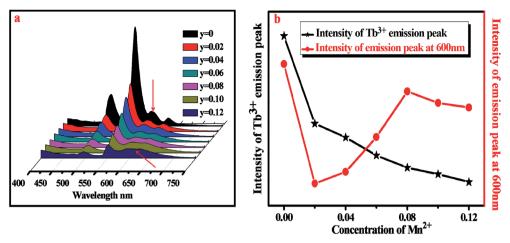

Fig. 9 (a) Emission spectra of BYP: $0.4\text{Tb}^{3+}$ , yMn<sup>2+</sup> (y = 0-0.12). (b) Relative emission intensity at 550 nm and 600 nm.

average lifetimes can be calculated and the results are shown in Fig. 10c. It can be seen that the lifetime of  $\mathrm{Tb}^{3+}$  decreases constantly as increasing  $\mathrm{Mn}^{2+}$  concentration, this can prove the energy transfer from  $\mathrm{Tb}^{3+}$  to  $\mathrm{Mn}^{2+}$  ( $\mathrm{ET}_{\mathrm{Ce-Tb}}$ ). In addition, the lifetime monitored at 600 nm shows a first decrease when y=0 rises to y=0.02, then increase when y=0.02 rises to y=0.08. This phenomenon is due to the low concentration of  $\mathrm{Mn}^{2+}$  at the beginning, the measured and calculated lifetimes are

mainly originated from  $Tb^{3+}$ , hence the lifetime decrease. When increased  $Mn^{2+}$  concentration, it passed into the lifetime of  $Mn^{2+}$ , thus the lifetime starts to increase.

The energy transfer efficiency of  $ET_{Tb-Mn}$  had been calculated by formula (3) and the results are shown in Fig. 10d. It can be seen that the energy transfer efficiency increases as  $Mn^{2+}$  concentration increasing and the maximum value is 52.3% when y=0.12. The critical distance from  $Tb^{3+}$  to  $Mn^{2+}$  ( $Rc_{Tb-Mn}$ )

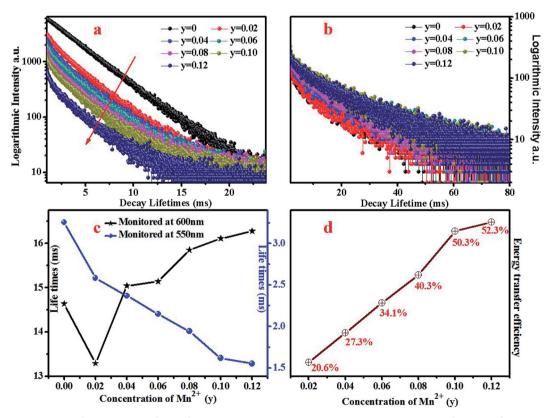

Fig. 10 (a) Decay curves of Tb<sup>3+</sup> in BYP:0.4Tb<sup>3+</sup>,yMn<sup>2+</sup> ( $\lambda_{em} = 550$  nm,  $\lambda_{ex} = 377$  nm). (b) Decay curves of Tb<sup>3+</sup> and Mn<sup>2+</sup> in BYP:0.4Tb<sup>3+</sup>,yMn<sup>2+</sup> ( $\lambda_{em} = 600$  nm,  $\lambda_{ex} = 377$  nm). (c) Lifetime of Tb<sup>3+</sup> and Mn<sup>2+</sup> as function of Mn<sup>2+</sup> concentration. (d) Energy transfer efficiency from Tb<sup>3+</sup> to Mn<sup>2+</sup> as function of Mn<sup>2+</sup> concentration.

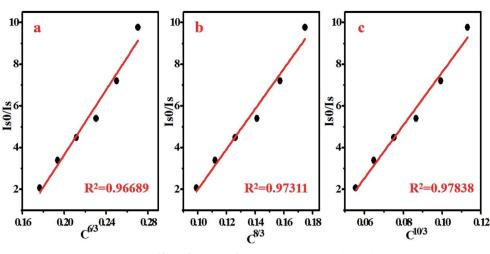

Fig. 11 Dependence of  $I_{s0}/I_s$  of Ce<sup>3+</sup> and Tb<sup>3+</sup> on  $C^{6/3}$ ,  $C^{8/3}$  and  $C^{10/3}$  in BYP:0.4Tb<sup>3+</sup>,yMn<sup>2+</sup>yMn<sup>2+</sup>.

can be calculated by expression (4), for BYP:0.4Tb<sup>3+</sup>,yMn<sup>2+</sup>,  $\chi_c$  is calculated to be 0.42 and the Rc<sub>Tb-Mn</sub> is calculated to be 13.84 Å which is obviously larger than the maximum distance of 5 Å for the exchange interaction. Thus it can be confirmed that the type of interaction between Tb<sup>3+</sup> and Mn<sup>2+</sup> is multipolar interaction. The linear relationship between  $I_0/I$  and  $C^{n/3}$  for BYP:0.4Tb<sup>3+</sup>,yMn<sup>2+</sup> are illustrated in Fig. 11a, and a well fitted curve can be gotten when n=10 and  $R^2=0.97838$ , therefore, it can be confirmed that the ET<sub>Tb-Mn</sub> mechanism is quadrupole–quadrupole interaction.

The Commission Internationale de L'Eclairage (CIE) chromaticity coordinates of BYP: $0.4\text{Tb}^{3+}$ , $y\text{Mn}^{2+}$  (y = 0.02–0.12) was calculated basing on the relevant emission spectra under 377 nm excitation. The calculated results along with luminescent photographs of related phosphors are depicted in Fig. 12, the emission color of BYP: $0.4\text{Tb}^{3+}$ , $y\text{Mn}^{2+}$  can be modulated from yellow-greenish (0.3329, 0.5275) to white (0.3936, 0.3562).

Thus, BYP:0.4Tb<sup>3+</sup>,yMn<sup>2+</sup> can act as a color-tunable material which can be used in near UV based white LEDs.

The temperature-dependent emission spectra of BYP:0.4Tb<sup>3+</sup>,0.12Mn<sup>2+</sup> excited by 377 nm was measured and shown in Fig. 13a, and the emission intensity of Tb<sup>3+</sup> and Mn<sup>2+</sup> is presented in Fig. 13b. It can be seen from Fig. 13a that the emission peak of Mn<sup>2+</sup> shifts from 600 nm to 588 nm due to the thermally active phonon-assisted excitation from lower energy levels to higher energy levels in the excited state of Mn2+.24 Because of the thermal quenching, the emission intensity of Mn<sup>2+</sup> decreases continually with the increase of temperature and remains 80.5% of the initial value (300 K) when the temperature reaches 425 K. However, the emission intensity of Tb<sup>3+</sup> increases continually, and when the temperature reaches 425 K the emission intensity rises to 111.6% of the initial value.

The abnormal change of emission intensity of Tb<sup>3+</sup> is also caused by the defects in BYP:0.4Tb<sup>3+</sup>,0.12Mn<sup>2+</sup>. Fig. 14a depicts the thermoluminescence spectrum of BYP:0.4Tb<sup>3+</sup>,0.12Mn<sup>2+</sup>, as

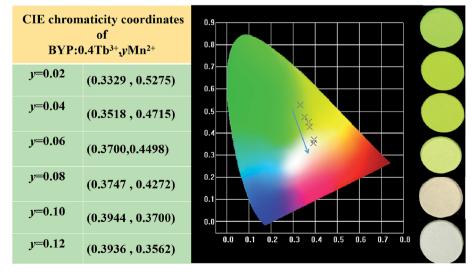

Fig. 12 CIE chromaticity coordinates of BYP:0.4Tb $^{3+}$ ,yMn $^{2+}$  (y = 0.02 - 0.12) along with their luminescent photographs.

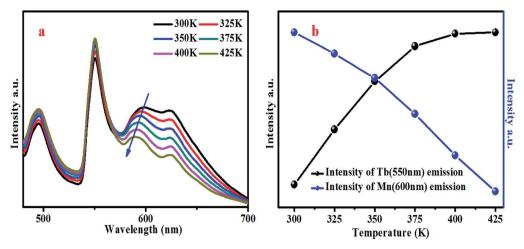

Fig. 13 (a) Temperature-dependent emission spectra of BYP:0.4Tb<sup>3+</sup>,0.12Mn<sup>2+</sup> excited by 377 nm. (b) Relative intensity of Tb<sup>3+</sup> and Mn<sup>2+</sup> in the temperature-dependent emission spectra.

mentioned in Chapter 3.2: the emission intensity change of Ce<sup>3+</sup> and Tb<sup>3+</sup> in temperature-dependent emission spectra of BYP:0.05Ce<sup>3+</sup>,0.45Tb<sup>3+</sup>. Fig. 14b is the schematic diagram on how the defects affect the emission intensity of Tb3+ in BYP:0.4Tb<sup>3+</sup>,0.12Mn<sup>2+</sup>.

#### 3.4 Luminescence and energy transfer of BYP:zCe<sup>3+</sup>,0.4Tb<sup>3+</sup>,0.12Mn<sup>2+</sup>

shows the emission BYP:0.15Ce<sup>3+</sup>,0.4Tb<sup>3+</sup>,0.12Mn<sup>2+</sup> excited by 330 nm, it can be seen that the emission peaks of Ce<sup>3+</sup> (390 nm), Tb<sup>3+</sup> (550 nm) and Mn<sup>2+</sup> (600 nm) coexist in the emission spectra covering blue, yellow, green and red region, thus, the efficient white emission is expectable. Fig. 15b depicts the excitation spectra of BYP:0.15Ce<sup>3+</sup>,0.4Tb<sup>3+</sup>,0.12Mn<sup>2+</sup> monitored at 390 nm, 550 nm and 600 nm, from which one can see that the obtained three spectra have the similar profile, it means that there is energy transfer among Ce<sup>3+</sup>, Tb<sup>3+</sup> and Mn<sup>2+</sup>. To further investigate the luminescence and energy transfer, the emission spectra of BYP:zCe<sup>3+</sup>,0.4Tb<sup>3+</sup>,0.12Mn<sup>2+</sup> under 330 nm excitation are shown in Fig. 15c, the relative intensity of Ce<sup>3+</sup>, Tb<sup>3+</sup> and Mn<sup>2+</sup> is depicted in Fig. 15d. It can be seen that the emission intensity of Ce<sup>3+</sup>, Tb<sup>3+</sup> and Mn<sup>2+</sup> increase continuously with increasing Ce<sup>3+</sup> concentration, it indicates that there are ET<sub>Ce-Tb</sub>, ET<sub>Ce-Mn</sub> and  $ET_{Tb-Mn}$  in BYP: $zCe^{3+}$ , 0.4 $Tb^{3+}$ , 0.12 $Mn^{2+}$ .

Fig. 16 shows the Commission Internationale de L'Eclairage (CIE) chromaticity coordinates of BYP:zCe<sup>3+</sup>,0.4Tb<sup>3+</sup>,0.12Mn<sup>2+</sup> (z = 0.01-0.11) and luminescent photographs of related phosphors when excited by 330 nm UV excitation. The emission color of BYP:zCe<sup>3+</sup>,0.4Tb<sup>3+</sup>,0.12Mn<sup>2+</sup> can be modulated from white (0.3030, 0.2893) with high color temperature to white (0.4096, 0.3770) with low color temperature, viz., a series of single-phased white light-emitting phosphors are realized successfully, and it maybe a potential application in white LEDs.

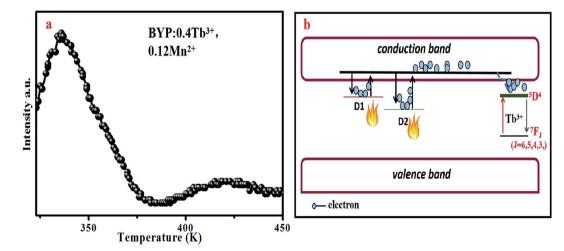

Fig. 14 (a) Thermoluminescence spectrum of BYP:0.4Tb<sup>3+</sup>,0.12Mn<sup>2+</sup>. (b) Schematic diagram of the interaction between the defect and temperature-dependent emission intensity in BYP:0.4Tb<sup>3+</sup>,0.12Mn<sup>2+</sup>.

Fig. 15 (a) Emission spectrum of BYP: 0.15Ce $^{3+}$ , 0.4Tb $^{3+}$ , 0.12Mn $^{2+}$  ( $\lambda_{ex}=330$  nm). (b) Excitation spectra of BYP: 0.15Ce $^{3+}$ , 0.12Mn $^{2+}$  ( $\lambda_{em}=390$  nm, 550 nm and 600 nm). (c) Emission spectra of BYP: zCe $^{3+}$ , 0.4Tb $^{3+}$ , 0.12Mn $^{2+}$  ( $\lambda_{ex}=330$  nm). (d) Relative intensity of Ce $^{3+}$ , Tb $^{3+}$  and Mn $^{2+}$  in BYP: zCe $^{3+}$ , 0.4Tb $^{3+}$ , 0.12Mn $^{2+}$ .

As a representative, BYP: $0.03\text{Ce}^{3^+}$ , $0.4\text{Tb}^{3^+}$ , $0.12\text{Mn}^{2^+}$  was chosen to explore the thermal stabilities. Fig. 17a depicts the temperature-dependent emission spectra of BYP: $0.03\text{Ce}^{3^+}$ , $0.4\text{Tb}^{3^+}$ , $0.12\text{Mn}^{2^+}$  under 330 nm UV excitation, Fig. 17b shows the emission intensity of  $\text{Ce}^{3^+}$ ,  $\text{Tb}^{3^+}$  and  $\text{Mn}^{2^+}$ .

Wavelength (nm)

The emission peak of Mn<sup>2+</sup> shifts from 600 nm to 587 nm with increasing the temperature and the reason is the same as that mentioned above, it is because of the thermally active phonon-assisted of Mn<sup>2+</sup>. With rising of temperature, the emission intensity of Mn<sup>2+</sup> decreases due to thermal quenching effect

Wavelength (nm)

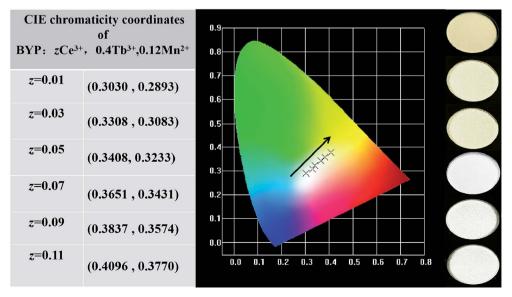

Fig. 16 CIE chromaticity coordinates of BYP:zCe<sup>3+</sup>,0.4Tb<sup>3+</sup>,0.12Mn<sup>2+</sup> (z = 0.01-0.11) along with their luminescent photographs.

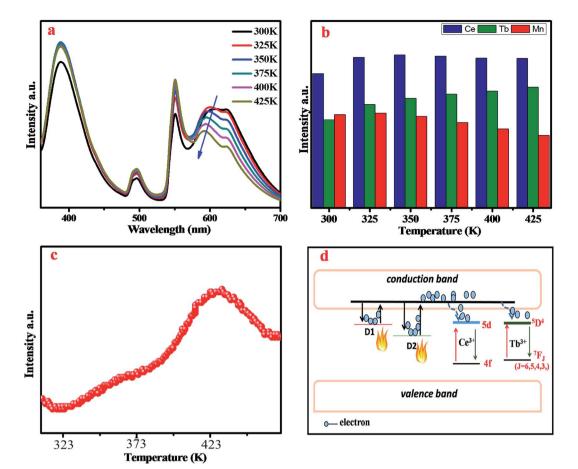

Fig. 17 (a) Temperature-dependent emission spectra of BYP:0.4Tb<sup>3+</sup>, 0.12Mn<sup>2+</sup> under 330 nm UV excitation. (b) Relative intensity of Ce<sup>3+</sup>, Tb<sup>3+</sup> and Mn<sup>2+</sup>. (c) Thermoluminescence spectrum of BYP:0.03Ce<sup>3+</sup>,0.4Tb<sup>3+</sup>,0.12Mn<sup>2+</sup>. (d) Schematic diagram of the interaction between the defect and temperature-dependent emission intensity in BYP:0.03Ce<sup>3+</sup>,0.4Tb<sup>3+</sup>,0.12Mn<sup>2+</sup>

and it still remains 80.8% of the initial value when the temperature rises to 425 K. The emission intensity of Ce<sup>3+</sup> shows a first increase and then decrease, the emission intensity of Tb<sup>3+</sup> increases constantly with increasing temperature. Fig. 17c presents the thermoluminescence spectrum of BYP:0.03Ce<sup>3+</sup>,0.4Tb<sup>3+</sup>,0.12Mn<sup>2+</sup>. The change in emission intensity of Ce3+ and Tb3+ is ascribed to the same theory as mentioned in chapter 3.2: the emission intensity change of Ce<sup>3+</sup> and Tb<sup>3+</sup> in temperature-dependent emission spectra of BYP:0.05Ce<sup>3+</sup>,0.45Tb<sup>3+</sup>. Fig. 17d is the schematic diagram on how the defects affect the emission intensity of Ce<sup>3+</sup> and Tb<sup>3+</sup> in BYP:0.03Ce<sup>3+</sup>,0.4Tb<sup>3+</sup>,0.12Mn<sup>2+</sup>.

#### Conclusions

In summary, a series of eulytite-typed and single-phased phosphors BYP: $0.05Ce^{3+}$ ,  $xTb^{3+}$ , BYP: $0.05Ce^{3+}$ ,  $yMn^{2+}$ BYP:2Ce<sup>3+</sup>,0.3Tb<sup>3+</sup>,0.14Mn<sup>2+</sup> were synthesized successfully. The energy transfer from Ce<sup>3+</sup> to Tb<sup>3+</sup> and Tb<sup>3+</sup> to Mn<sup>2+</sup> were confirmed by analyzing its spectra and fluorescence lifetime. The thermal stability of samples is extraordinary, and it had been proved that the unusual temperature performance is caused by the defects in the samples. Finally, a series of singlephased color-tunable with high thermal stability phosphors were obtained, especially BYP:zCe<sup>3+</sup>,0.3Tb<sup>3+</sup>,0.14Mn<sup>2+</sup>, it can emit warm white light and the color temperature can be modulated by the energy among Ce3+, Tb3+ and Mn2+. Thus, it may have application potential in white LEDs.
