Asymmetric amination of α,α -dialkyl substituted aldehydes catalyzed by a simple chiral primary amino acid and its application to the preparation of a S1P₁ agonist†

Qiong Xiao,^a Yifan Tang,^b Ping Xie^{*a} and Dali Yin^{*a}

The chiral catalytic amination of an α,α -dialkyl substituted aldehyde usually proceeds with low enantioselectivity. We selected naphthyl-L-alanine as the catalyst and observed improved enantioselectivity for the amination. Using this method, racemic α -methyl- α -benzyloxypropanal was aminated to give chiral serine derivatives in 74% ee, which was further increased to >99% ee after recrystallization. Moreover, we also successfully synthesized a chiral phosphonium salt **9** for the preparation of one α -substituted alaninol compound **14** as an S1P₁ agonist in high overall yield.

Introduction

α,α -Disubstituted amino alcohols, aldehydes and acids are important chiral building blocks in organic synthesis. They are routinely found in a number of peptides,^{1–5} natural products^{6,7} and pharmaceuticals.^{8,9} Due to this importance, their synthesis has attracted sustained interest from the synthetic community. Existing methods for the asymmetric approach to scaffolds include classical Seebach's method,^{10,11} auxiliary Strecker synthesis,¹² and a variety of asymmetric phase transfer catalysis reactions.¹³

Recently, several methods have been reported describing the asymmetric Michael α -amination of achiral aldehydes *via* proline catalysis, resulting in the products being obtained in good yields and excellent enantioselectivities.^{14–17} However, these proline catalysts do not imbue high enantioselectivities in the amination of branched aldehydes. Wang *et al.* reported that 3-(1-naphthyl)-L-alanine (**1d**) successfully promoted the enantioselective α -amination of branched aldehydes with azodicarboxylates to give α -alkyl- α -aryl disubstituted aldehydes in up to 99% ee.¹⁸ However, low enantioselectivities only 4–28% ee were obtained with α -alkyl- α -alkyl disubstituted, potentially owing to poor stereo-differentiation between the two α -substituents.¹⁴ To some extent, the application of this kind of reaction is limited. In 2005, Barbas *et al.* reported higher

stereoselectivities were possible utilizing proline derived tetrazole catalyst (**1b**) for the amination of α -alkyl- α -benzyl disubstituted aldehydes.¹⁹ In addition, no further progress about the asymmetric amination of α -alkyl- α -alkyl disubstituted aldehydes had been reported.

Results and discussion

Herein, we report the asymmetric Machel α -amination of α -methyl- α -protected hydroxymethyl aldehydes and their subsequent reduction and cyclisation to afford oxazolidinones in good ee. We initially chose 3-(benzyloxy)-2-methylpropanal and dibenzyl azodicarboxylate (DBAD) as a model substrate to determine to optimal reaction conditions. When L-proline (**1a**) (30 mol%) was used,¹⁴ the reaction was complete in 48 hours at room temperature and provided the amino aldehyde in 56% yield, however we obtained poor enantioselectivities (32% ee). To improve the enantioselectivity, we screened a number of catalysts (Fig. 1). For example, tetrazole catalyst (**1b**) (15 mol%) in CH₃CN provided 42% ee with 68% yield (Table 1, entry 2).¹⁷ 3-(1-Naphthyl)-L-alanine catalyst (**1d**) (15 mol%) in CH₃CN gave the amino aldehyde in 70% yield with 46% ee (Table 1, entry 4).¹⁸

We then turned our attention to the effects of solvents on both yield and enantioselectivities (Table 2). Among them, dioxane, MeOH, MTBE and THF (entries 9, 10, 7 and 8) were all tolerated and produce the desired oxazolidinones in moderate

to good enantioselectivities. Of particular note, THF delivered the highest enantioselectivity (69% ee) in synthetically useful yields.

Furthermore, when lowering temperature to 0 °C, we observed no improvement in enantioselectivity, however the reaction became notably more sluggish. Increasing catalyst loading up to 30 mol% did not improve either enantioselectivity or reaction time.

With these optimized conditions in hand, we probed the substrate scope of the reaction (Table 3). In general, various oxazolidinones **5** were obtained in moderate to good yields (54–89%) and enantioselectivities (24–73% ee). The reactions showed poor enantioselectivities for α -methyl- α -ethyl and α -methyl- α -carbethoxy disubstituted aldehydes, but not for α -

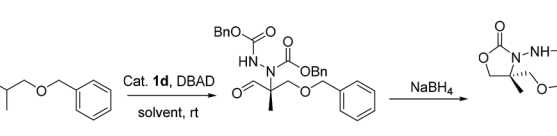

methyl- α -protected hydroxymethyl substituted aldehydes with aromatic ring. The results also showed that electron-withdrawing groups were more successful than electron-donating groups. Moreover, *p*-F and *p*-CF₃ substituents both showed similar enantioselectivities. We then investigated differing azodicarboxylates and observed that di-*p*-chlorobenzyl azodicarboxylate (DCAD) provided the desired products in excellent yields (90%) and good enantioselectivities (up to ee 74%) while lower enantioselectivities were obtained with diethyl azodicarboxylate (DEAD) or diisopropyl azodicarboxylate (DIAD). We also observed good enantioselective control with catalysts bearing naphthalene rings. This may be due to the π - π interaction between the aromatic ring of substrate and naphthalene ring limiting the conformation of the intermediate, thus improving the level of stereo-differentiation between the two α -substituents. Additionally, when the azo reagent contained an aromatic ring this π - π interaction may be further enhanced, resulting in the observed improvement of stereoselectivity.

Upon recrystallization from 90% ethanol, the aldehyde **4a-p-ClBn** was obtained in 97% ee (60% yield) and **4h-p-ClBn** was obtained in 97% ee (65% yield), which was subsequently converted to oxazolidinone **5a-p-ClBn** in >99% ee and **5h-p-ClBn** was obtained in 98% ee respectively. The absolute configuration of **5-R** was determined to be (*R*) on CD spectrum. Under ambient pressure, hydrogenation using 10% Pd/C in methanol/acetic acid, the benzyloxycarbonyl group was removed. Cleavage of the hydrazine moiety, **7** was accomplished by treating with NaNO₂ (ref. 14) (Scheme 1). Alcohol **7** was treated with *p*-TsCl in pyridine, and the resulting tosylate was successively converted to iodide **8** with NaI in acetone under a reflux condition.²⁰ **8** with triphenylphosphine in DMF provided the desired phosphonium salt **9** in moderate yield as a stable white solid.²⁰

Then we applied the chiral phosphonium salt **9** to the synthesis of biological active compound as S1P₁ agonist **14**. These types of compounds possessing a chiral 2-methyl-2-aminoethanol have shown promise in recent years as the immunosuppressant.^{21,22} This compound is an analogue of SYL930, an immunosuppressant we have been reported before.²³ SYL930 is currently in phase I clinical stage. The synthesis of **14** started from the aldehyde **11** in only a three step manipulation.²⁴ Aldehyde **11** was synthesized in good yield from 4-bromobenzaldehyde and binary pinacol borate ester **10** via Suzuki reaction with Pd-dimer (dibromobis(tri-*tert*-butylphosphine)dipalladium) as the catalyst.²⁴ The Wittig reaction of **9** with **11** in dry THF at –78 °C for 3 h furnished the alkenes **12** in good yield. Subsequently reducing with 10% Pd/C in MeOH for 1 h afforded compound **13** in virtually quantitative yield after a flash-filtration. Finally, hydrolysis of the oxazolidinone part and then acidification with 1 M HCl in Et₂O produced the chiral α -substituted alaninol compound **14**.

Conclusions

In this study, we presented an efficient asymmetric amination of branched racemic aldehydes catalyzed by the commercially available amino acid (3-(1-naphthyl)-L-alanine). Under the

optimized conditions, we obtained α -methyl- α -protected hydroxymethyl substituted aldehydes in high ee. Importantly, we developed an efficient catalytic method for synthesizing the Wittig reagent involving a chiral 2-methyl-2-aminoethanol structure that could be applied to other syntheses. Further, a new S1P₁ agonist **14** has been obtained by this method in high overall yield.

Experimental

General procedure for the synthesis of 4,4-disubstituted 3-alkoxycarbonylamino-oxazolidin-2-ones (5-*R*) by one pot method

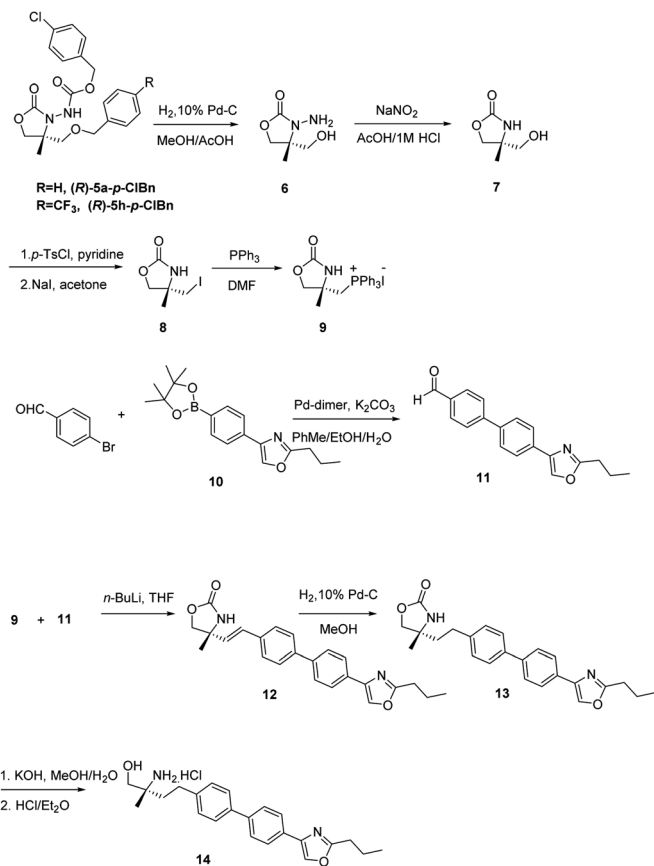

Catalyst **1d** (15 mol% in respect to the azodicarboxylate) was added to a suspension of aldehydes (**2**, 1.5 eq. in respect to the azodicarboxylate) and azodicarboxylate (**3**) in THF. The mixture stirred at rt under argon until the colour of the azodicarboxylate

had disappeared. NaBH₄ (3 eq. in respect to the azodicarboxylate) was added in portions at room temperature. The reaction mixture was stirred for 1 h, and then it was quenched by adding 1 M HCl aq. until the mixture reached pH 7, and it was extracted with CH₂Cl₂. The combined organic phases were dried over Na₂SO₄, and the solvent was evaporated under reduced pressure. The resulting crude was purified by flash chromatography on silica gel eluted with light petroleum ether–ethyl acetate mixture (4 : 1 v/v) to afford products 5-*R* as oil or solid.
