Branched polyethyleneimine-assisted 3-carboxybenzoboroxole improved Wulff-type boronic acid functionalized magnetic nanoparticles for the specific capture of *cis*-diol-containing flavonoids under neutral conditions

Daojin Li, * Zheyao Liu, Rumeng Song, Wenliu Yang, Simeng Zhai and Wenhui Wang

Flavonoids have shown a variety of biological activities such as antimicrobial, antibacterial, antifungal, antiviral, antiinflammatory, antitumor, antiatherogenic, and antihyperglycemic activities. A lot of important flavonoids contain *cis*-diols such as rutin (Ru), quercetin (Qu), luteolin (Lu), myricetin (Myr) and baicalein (Ba) and so on. It is necessary to establish a simple, low-cost and efficient purification method for *cis*-diol-containing flavonoids from plant extracts. Boronate affinity materials are able to reversibly bind the *cis*-diols *via* boronic acids by forming a five- or six-membered boronic cyclic ester in aqueous media. However, conventional boronate affinity materials have to be used in alkaline media, which can lead to the oxidation of *cis*-diols in compounds. In this study, the polyethyleneimine (PEI)-assisted 3-carboxybenzoboroxole-functionalized magnetic nanoparticles (MNPs) were prepared to achieve efficient capture of *cis*-diol-containing flavonoids under neutral conditions. Branched PEI was applied as a scaffold to amplify the number of boronic acid moieties, while 3-carboxybenzoboroxole, exhibiting high affinity and excellent water solubility toward flavonoids, was used as an affinity ligand. The prepared boronate affinity MNPs exhibited high binding capacity and fast binding kinetics (equilibrium in 3 min) under neutral conditions. In addition, the obtained boronate affinity MNPs exhibited high binding affinity ($K_d \approx 10^{-4}$ M), low binding pH (pH \geq 6.0) and tolerance of the interference to abundant sugars.

Introduction

Flavonoids are plant-derived dietary components defined by a diphenylpropane (C6–C3–C6) skeleton, which consist of a large group of heterogeneous polyphenols.^{1,2} Flavonoids can be found in fruits, vegetables, herbaceous plants, flowers, tea, honey, coffee and wine, *etc.*³ Pharmacological studies of flavonoids have shown a variety of biological activities such as antimicrobial, antibacterial, antifungal, antiviral, antiinflammatory, antitumor, antiatherogenic, antihyperglycemic activities and fighting acetaminophen-mediated hepatotoxicity, especially antioxidant activities.^{4–9} Many biological and pharmacological properties of flavonoids are associated with free radical-scavenging actions because free radicals are considered to be important causative factors in the development of various diseases.¹⁰ Clearly, flavonoids are highly beneficial for human health *via* interacting with a number of cellular targets involved in critical cell signalling pathways in the body. A lot of flavonoids contain *cis*-diols such as rutin, quercetin, luteolin,

myricetin, fisetin, leptosidin, aureusidin and baicalein, and so on. The type of *cis*-diol-containing flavonoids is unique classes of flavonoids, which exhibits a variety of biological activities. Therefore, it is extremely important to determine *cis*-diol-containing flavonoids in real samples such as fruits, vegetables, herbaceous plants, flowers, tea, honey, coffee, wine and so on. Spectrophotometric methods are suitable for determining *cis*-diol-containing flavonoids because the equipment is simple and easy to operate. However, some interfering components in the sample matrix affect the analysis. Therefore, it is necessary to establish a simple, low-cost and efficient purification method for *cis*-diol-containing flavonoids from plant extracts.

Boronate affinity is a unique means for the selective extraction and separation of *cis*-diol-containing compounds.^{11–37} Boronic acids are able to covalently interact with *cis*-diol-containing compounds to form five- or six-membered cyclic esters usually under alkaline pH conditions and the cyclic esters dissociate when the environmental pH is changed to acidic. However, the use of alkaline media is easy to oxidize the *cis*-diols of *cis*-diol-containing flavonoids.³⁸ In addition, the discharge of alkaline aqueous solution may cause secondary pollution in water, which requires additional separation treatments. Thus, boronic acid-functionalized materials that can

function at neutral pH would be highly desirable for the separation and purification of *cis*-diol-containing flavonoids. As far as we know, a variety of attempts have been made to reduce the binding pH. Up to date, four types of boronic acid monomers with low pK_a values can provide low binding pH: (1) boronic acid ligands with electron-withdrawing groups, such as nitro, fluoro and sulfonyl on the phenyl ring;^{39,40} (2) Wulff-type boronic acids, which contain intramolecular tetracoordinated B–N or B–O bonds;^{41,42} (3) improved Wulff-type boronic acids, which contain intramolecular tricoordinated B–O bonds;^{43,44} and (4) heterocyclic boronic acids.^{45,46} The above mentioned structures of boronic acid ligands can be used to prepare boronate affinity materials with low binding pH. Among them, improved Wulff-type boronic acids, which are called benzoboroxoles, contain intramolecular tricoordinated B–O bonds rather than the classical intramolecular tetracoordinated B–N or B–O bonds in the molecular structure. Due to their unique structure, benzoboroxoles display the advantages of a low pK_a value (7.3), excellent hydrophilicity and improved *cis*-diol binding capability under neutral conditions. Among the benzoboroxoles family, 3-carboxybenzoboroxole possesses lower pK_a value (6.9) and higher affinity to *cis*-diol-containing compounds due to the electron-withdrawing effect of carboxyl.⁴⁷ Therefore, 3-carboxybenzoboroxole is considered as a powerful ligand to prepare boronate affinity materials. For example, researchers have prepared boronate affinity monolithic column through using the improved Wulff-type boronic acids as ligand for the selective capture of nucleosides/glycoproteins/glycopeptides under neutral or acidic conditions.^{47–49} However, such materials have not been used in the large-scale *cis*-diol-containing flavonoids enrichment. In addition, the binding capacity of monolithic columns is usually lower than that of nonmaterial. Therefore, the development of 3-carboxybenzoboroxole-functionalized nanomaterials might be of great significance to achieve efficient capture of *cis*-diol-containing flavonoids under neutral or acidic conditions. There is no report about boronic acid-functionalized nanomaterials resulted from improved Wulff-type boronic acids for capture of *cis*-diol-containing flavonoids.

However, the binding capacity of single boronic acids functionalized materials toward *cis*-diol-containing compounds is relatively low. Through amplification of the number of boronic acid moieties using highly branched poly(amidoamine) (PAMAM) dendrimers or polyethyleneimine (PEI), the boronic acid functionalized materials exhibited a significantly improved binding capacity. Compared with PAMAM, the branched PEI can be used as a better scaffold to amplify the number of boronic acid moieties because of its flexible chains, hydrophilic properties, easy post-modification, plentiful amino groups and low cost. Thus, it is essential to develop PEI-assisted improved boronic acids-functionalized nanomaterials for the specific capture of *cis*-diol-containing flavonoids under neutral pH condition.

In the study, we applied 3-carboxybenzoboroxole as ligands to prepare PEI-assisted boronic acid-functionalized magnetic nanoparticles (MNPs) for highly efficient capture of *cis*-diol-containing flavonoids under neutral condition. In this work,

magnetic Fe_3O_4 nanoparticles were used as supporting nanomaterials due to their good biocompatibility, superparamagnetic property, low toxicity and easy preparation. Firstly, amino-functionalized MNPs were synthesized and then PEI modified MNPs were prepared. Subsequently, PEI modified MNPs were functionalized with boronic acid by the amidation between amino of PEI and carboxyl of 3-carboxybenzoboroxole. Due to the PEI-amplified boronic acid sites, the binding capacity of the obtained PEI-assisted boronic acid-functionalized MNPs was significantly enhanced. The prepared boronate affinity MNPs exhibited fast binding kinetics (equilibrium in 3 min) under neutral condition. In addition, the obtained boronate affinity MNPs exhibited high binding affinity ($K_d \approx 10^{-4}$ M) and low binding pH ($pH \geq 6.0$).

Experimental

Reagents and materials

Branched polyethyleneimine (PEI) ($M_w = 600, 1800, 10\ 000$ and $70\ 000$), 3-carboxybenzoboroxole (CBO), rutin (Ru), quercetin (Qu), luteolin (Lu), myricetin (Myr), genistein (Gen), isorhamnetin (Iso), and kaempferol (Kae) were from J&K Scientific (Shanghai, China). Ferric chloride hexahydrate ($FeCl_3 \cdot 6H_2O$), anhydrous sodium acetate (NaOAc), ethylene glycol, sodium cyanoborohydride, anhydrous methanol, glutaraldehyde, 1,6-hexanediamine, 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide (EDC) and *N*-hydroxysuccinimide (NHS) were purchased from Alfa Aesar (Tianjin, China). All used reagents were of analytical grade. All commercially available reagents were used without further purification. Water used in all the experiments was purified by a Milli-Q Advantage A10 ultrapure purification system (Millipore, Milford, USA).

Instruments

Transmission electron microscopy (TEM) was performed on a JEM-1010 system (JEOL, Tokyo, Japan). Powder X-ray diffraction (XRD) analyses were carried out using a Bruker D8 Advance diffractometer with $Cu\ K\alpha$ radiation and the scanning angle ranged from 10° to 80° of 2θ . UV absorbance data were acquired from a U-3010 UV spectrophotometer equipped a 1 cm cuvette (Kyoto, Japan). The magnetic properties were measured with a vibrating sample magnetometer (VSM) (LDJ 9600-1, USA). The magnetic properties were measured with a vibrating sample magnetometer (VSM) (LDJ 9600-1, USA).

Preparation of $Fe_3O_4@PEI@CBO$

The procedure for the synthesis of $Fe_3O_4@PEI@CBO$ was depicted in Fig. 1. It included three steps: (1) synthesis of amino-functionalized magnetic nanoparticles (Fe_3O_4 NPs), (2) preparation of PEI modified MNPs ($Fe_3O_4@PEI$), and (3) functionalization with 3-carboxybenzoboroxole (CBO). The Fe_3O_4 NPs were synthesized based on a previously reported method⁵⁰ with minor modification. Briefly, ferric trichloride hexahydrate (2.0 g) was first dissolved in ethylene glycol (60 mL) to form a clear orange yellow color solution. Then, anhydrous sodium acetate (4.0 g) and 1,6-hexanediamine (13.0 g) was added to the

Fig. 1 Synthesis routes of Fe₃O₄@PEI@CBO.

above solution. Finally, the mixture was stirred vigorously for 40 min and sealed in a PTFE-lined autoclave and reacted at 198 °C for 6 h. The resulting Fe₃O₄ NPs were rinsed with water and ethanol for 3 times each, and then dried at 50 °C in a vacuum overnight. After 200 mg Fe₃O₄ NPs were added to 40 mL anhydrous methanol containing 5% glutaraldehyde, the mixture was mechanically stirred for 12 h at room temperature. The resulting glutaraldehyde-activated Fe₃O₄ NPs were collected by a magnet and then dispersed in 40 mL anhydrous methanol containing 0.6 g PEI by ultrasound. The mixture was mechanically stirred (600 rpm) for 12 h at room temperature. After that, 15 mg mL⁻¹ sodium cyanoborohydride was added (200 mg every 6 hours) during the course of reaction for 24 h. The Fe₃O₄@PEI were collected by a magnet and washed with water and ethanol for 3 times each, and then dried at 50 °C overnight. To carry out boronic acid-functionalization of Fe₃O₄@PEI, 30 mg of Fe₃O₄@PEI was first dispersed into 30 mL of 50 mM phosphate buffer (pH 7.4), and then the solution was ultrasonicated for 3 min. After that, 270 mg of EDC and 140 mg of NHS were added into the solution. After ultrasonicated for 20 s, the obtained solution was vigorously stirred for 40 min at 25 °C. After that, 100 mg of CBO was added and the mixture was kept shaking for 20 min at 25 °C and then kept at room temperature for 24 h. The Fe₃O₄@PEI@CBO was separated from reaction mixtures using a magnet and washed with water and ethanol and dried at 50 °C. The obtained Fe₃O₄@PEI@CBO was stored for further use.

Selectivity of Fe₃O₄@PEI@CBO

The selectivity of Fe₃O₄@PEI@CBO was evaluated using rutin (Ru), quercetin (Qu), luteolin (Lu) and myricetin (Myr) as *cis*-diol-containing test flavonoids while genistein (Gen), isorhamnetin (Iso), and kaempferol (Kae) were used as non-*cis*-diol analogue. First, a solution for each flavonoid of 0.5 mg mL⁻¹ was separately prepared with 50 mM phosphate buffer (pH 7.0). Then equivalent Fe₃O₄@PEI@CBO were added to 500 μL of the flavonoid solutions in centrifugal tubes, respectively. Then, the

centrifugal tubes were shaken on a rotator at room temperature for 2 h. The Fe₃O₄@PEI@CBO were then collected at the tube wall by applying a magnet and rinsed with 500 μL of 50 mM sodium phosphate buffer (pH 7.0) for three times. After washing, the MNPs were re-suspended and eluted in 100 μL of acetic acid solution for 1 h on a rotator. Finally, the MNPs were trapped to the tube wall by using a magnet and the eluates were collected. The amounts of these flavonoids adsorbed by the Fe₃O₄@PEI@CBO were determined by measuring the eluates in terms of UV absorbance at maximum absorption wavelength. The measurement was repeated with three times.

Kinetic adsorption experiment

0.50 mg mL⁻¹ of rutin or quercetin dissolved in 50 mM phosphate buffer (pH 7.0) was applied as a representative sample. The kinetic adsorption experiment was performed as follows: the suspension containing 3 mg Fe₃O₄@PEI@CBO was added to 0.5 mL of rutin or quercetin solution and shaken different durations from 1 to 14 min at room temperature. The MNPs were collected by using external magnetic force and rinsed with 500 μL of 50 mM phosphate buffer (pH 7.0) for three times. After washing, rutin or quercetin bound on Fe₃O₄@PEI@CBO was eluted in 100 μL acetic acid solutions (pH 2.7) for 1 h on a rotator and the concentration of rutin or quercetin in the supernatant was measured by absorbance analysis.

Measurement of adsorption isotherm and Scatchard analysis

The measurement of adsorption isotherm was performed according to the following process. Briefly, Fe₃O₄@PEI@CBO was first dispersed to 50 mM phosphate buffer to homogenize the NPs (15 mg mL⁻¹). After Fe₃O₄@PEI@CBO of the above suspension (200 μL) were collected by a magnet, 300 μL solutions of different concentrations of rutin or quercetin were added to the above Fe₃O₄@PEI@CBO and shaken on a rotator for 1 h at room temperature. Thereafter, Fe₃O₄@PEI@CBO with trapped rutin or quercetin were separated by using an external magnetic force and then washed with 300 μL of 50 mM sodium phosphate buffer (pH 7.4) for 3 times each. Finally, the components bound on the NPs were eluted by 100 mM acetic acid solution. The eluent containing rutin or quercetin adsorbed by the NPs was measured with UV-vis spectrophotometer.

The Scatchard analysis was implemented according to a previously reported method.⁴³ Dissociation constant (K_d) and apparent maximum binding capacity (Q_{max}) were evaluated according to the following Scatchard equation:

$$\frac{Q_e}{C_s} = \frac{Q_{max}}{K_d} - \frac{Q_e}{K_d}$$

where Q_{max} and K_d is the saturated binding capacity and the dissociation constant, respectively, Q_e is the binding amount of rutin or quercetin to Fe₃O₄@PEI@CBO at equilibrium, C_s is the free concentration at adsorption equilibrium. The values for K_d and Q_{max} can be calculated from the slope and the intercept of plots of Q_e/C_s versus Q_e .

Reproducibility and reusability

The experiment on reproducibility of $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ was carried out through adding 3 mg of five batches of dry products prepared on different time into 0.3 mL of rutin or quercetin solution at a concentration of 0.50 mg mL^{-1} . The remaining steps were the same as binding isotherm experiment. To estimate the reusability of $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$, 3 mg of dry MNPs was added to 0.3 mL of rutin or quercetin solution at a concentration of 0.50 mg mL^{-1} and incubated for 30 minutes at room temperature. Then, the products were separated by an external magnet. The recovered NPs were washed with 5 mL acetonitrile-acetic acid (1/2, v/v) for 2 hours to ensure complete removal of the residual quercetin in $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$. $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ were washed with water several times, then dried under vacuum overnight and reused for the adsorption of rutin or quercetin again. The adsorption-regeneration cycle was repeated ten times with the same $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$.

Results and discussion

Characterization of the magnetic nanoparticles (MNPs)

The morphology of the prepared MNPs was characterized by transmission electron microscopy (TEM). As depicted in Fig. 2A, TEM images of $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ revealed that the MNPs had good dispersibility and relatively homogeneous size

Fig. 2 TEM images of $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ and magnetic hysteresis curves of bare MNPs (A) and $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ (B).

distribution. The average diameter of the $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ was estimated to be about 100 nm. The magnetization of the bare MNPs and $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ was measured using VSM and the resulting magnetic hysteresis curves are shown in Fig. 2B. The saturation magnetizations of bare MNPs and $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ were 80.32 and 71.75 emu g^{-1} , respectively, which indicates superparamagnetic behavior. The decrease of the saturation magnetization of $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ in comparison with bare MNPs results from the formed modification layers, which could shield the magnetite to some extent. The crystalline nature of $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ has also been confirmed by XRD analysis (Fig. 3), considering the several sharp peaks corresponding to the crystalline planes of cubic spinel nanostructure of the magnetic nanoparticles.

Selectivity

The selectivity of the obtained $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ was first investigated using rutin (Ru), quercetin (Qu), luteolin (Lu) and myricetin (Myr) as *cis*-diol-containing test flavonoids and genistein (Gen), isorhamnetin (Iso), and kaempferol (Kae) as non-*cis*-diol analogue. As depicted in Fig. 4, $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ exhibited higher binding capacity for *cis*-diol-containing flavonoids than that for non-*cis*-diol flavonoids, which indicated good selectivity.

Optimization of the molecular weight of PEI

Generally, the larger the molecular weight of PEI is, the more amine groups it can provide. However, once the molecular weight of PEI exceeds a certain value, a portion of amine groups may become inaccessible. Thus, it is necessary to investigate the effect of the molecular weight of PEI on the number of the binding sites. The number of the binding sites can be reflected by binding capacity (Q , mg g^{-1}). To determine which molecular weight of PEI can obtain the highest binding capacity, we investigated the effect of the chain length of PEI on the binding capacity. It should be noted that the amount of functional monomer can be guaranteed to be excess. We investigated which amount of functional monomer is excess for the adsorption capacity before optimizing the molecular weight of PEI. As depicted in Fig. 5, the binding capacity increased with

Fig. 3 XRD pattern of $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$.

Fig. 4 Comparison of the amount of different analytes captured by $\text{Fe}_3\text{O}_4\text{@PEI@CBO}$. Binding buffer: 50 mM sodium phosphate buffer (pH 7.0); elution solution: 100 mM HAc (pH 2.7); samples: 0.50 mg mL^{-1} Ru, Qu, Lu, Myr, Gen, Iso, or Kae dissolved in binding buffer.

the increase of molecular weight of PEI from 600 to 10 000 regardless of Ru or Qu. However, when PEI 70,000 was used, the binding capacity is lower than that when using PEI 10000. The

Fig. 5 Comparison of the amount of Ru (A) and Qu (B) samples captured by $\text{Fe}_3\text{O}_4\text{@PEI@CBO}$ through changing molecular weight of PEI. Binding buffer: 50 mM sodium phosphate buffer (pH 7.0); elution solution: 100 mM HAc (pH 2.7); samples: 0.50 mg mL^{-1} rutin (Ru) quercetin (Qu).

PEI 10,000-modified 3-carboxybenzoboroxole-functionalized MNPs were considered as the optimal $\text{Fe}_3\text{O}_4\text{@PEI@CBO}$ for further investigations and application.

Determination of Q_{max} and K_d

Binding capacity is a crucial factor in boronate affinity materials. It determines the maximum amount of targets that an affinity material can capture. On the other hand, binding affinity is an important binding property of boronate affinity materials, which can determine how low the concentrations of *cis*-diol-containing flavonoids can be enriched by $\text{Fe}_3\text{O}_4\text{@PEI@CBO}$. The maximum binding capacity (Q_{max}) and dissociation constant (K_d) of $\text{Fe}_3\text{O}_4\text{@PEI@CBO}$ with rutin (M_w : 610) and quercetin (M_w : 302) were evaluated using UV-vis spectrophotometry.

We first investigated binding capacity and binding strength of $\text{Fe}_3\text{O}_4\text{@PEI@CBO}$ toward rutin. As shown in Fig. 6, according to binding isotherms and Scatchard plots analyses, Q_{max} and K_d values of $\text{Fe}_3\text{O}_4\text{@PEI@CBO}$ were calculated to be $(3.21 \pm 0.23) \text{ mg g}^{-1}$ and $(1.01 \pm 0.10) \times 10^{-4} \text{ M}$, respectively. We further investigated the binding capacity and binding strength of the $\text{Fe}_3\text{O}_4\text{@PEI@CBO}$ toward quercetin. The binding isotherms and Scatchard plots for quercetin were shown in Fig. 7. The Q_{max} and K_d values of $\text{Fe}_3\text{O}_4\text{@PEI@CBO}$ were evaluated to be $(4.29 \pm 0.21) \text{ mg g}^{-1}$ and $(3.62 \pm 0.21) \times 10^{-4} \text{ M}$, respectively. Clearly, the rutin exhibited nearly four folds lower K_d value than quercetin for $\text{Fe}_3\text{O}_4\text{@PEI@CBO}$. This possible

Fig. 6 Binding isotherms (A) and Scatchard plots (B) for the binding of $\text{Fe}_3\text{O}_4\text{@PEI@CBO}$ with rutin (Ru).

Fig. 7 Binding isotherms (A) and Scatchard plots (B) for the binding of $Fe_3O_4@PEI@CBO$ with quercetin (Qu).

explanation is that as rutin contains a pair of *cis*-diols, there is synergistic effect on the $Fe_3O_4@PEI@CBO$ to some extent, which can greatly improve binding strength of $Fe_3O_4@PEI@CBO$ toward rutin. In contrast, quercetin contains only one *cis*-diol group, there is no synergistic effect on the $Fe_3O_4@PEI@CBO$. Clearly, the reason for the lower binding constant of the $Fe_3O_4@PEI@CBO$ toward quercetin is the absence of synergistic effect of multiple binding. In addition, the K_d value for rutin is also a little lower than those the previous boronate affinity materials provided for other single *cis*-diol such as adenosine^{45,46} due to synergistic effect.

However, although rutin exhibited higher binding affinity than quercetin for $Fe_3O_4@PEI@CBO$, the Q_{max} of rutin was a little lower than that of quercetin (Table 1). This is because that rutin occupies more binding sites of boronic acid moieties as compared with quercetin.

Table 1 Dissociation constants (K_d) and binding capacity (Q_{max}) of $Fe_3O_4@PEI@CBO$ for Ru and Qu

	K_d (M)	Q_{max} ($\mu\text{mol g}^{-1}$)	R^2
Ru	$(1.01 \pm 0.10) \times 10^{-4}$	3.21 ± 0.23	0.94
Qu	$(3.62 \pm 0.21) \times 10^{-4}$	4.29 ± 0.21	0.98

In a word, the amplified number of boronic acid moieties by using PEI as a scaffold can improve greatly the binding affinity of $Fe_3O_4@PEI@CBO$ toward flavonoids with multiple *cis*-diols but fails to improve even reduce the binding capacity.

Adsorption time

An appropriate adsorption time to obtain high binding capacity is required in the extraction and separation procedure. The effect of extraction time on the extraction efficiency of flavonoids was investigated by varying from 1 min to 10 min (Fig. 8). As depicted in Fig. 8, the binding capacity of Ru or Qu onto $Fe_3O_4@PEI@CBO$ had a fast adsorption rate within the first 2 min because amount of binding sites at the beginning enabled Ru or Qu to be easily adsorbed to $Fe_3O_4@PEI@CBO$ with less resistance. Besides, the binding capacity reached a maximum value at an adsorption time of 3 min. When the extraction time was increased from 3 to 6 min, the binding capacity remained essentially constant. These results indicate that extraction equilibrium could be achieved in 3 min, implying that most of the binding sites had been occupied by Ru or Qu in such a situation. This total adsorption time in the prepared boronate affinity materials is much shorter than that in other boronate affinity materials (30–90 min).^{51–55} This may be ascribed to its excellent adsorption of flavonoids during the extraction. In the light of these results, 3 min was chosen as the optimum adsorption time for extraction. This result indicates that the mass transfer speed in the $Fe_3O_4@PEI@CBO$ prepared by the proposed method was fast.

The lowest extractable concentration of rutin and quercetin

As we know, binding strength can determine how low extractable concentration of *cis*-diol-containing flavonoids. As $Fe_3O_4@PEI@CBO$ exhibited significantly increased binding affinity towards rutin due to the amplified number of boronic acid

Fig. 8 Binding equilibrium of $Fe_3O_4@PEI@CBO$ with Ru and Qu. Sample: 0.50 mg mL^{-1} Ru containing 50 mM phosphate, pH 7.0.

moieties, $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ were able to extract rutin of lower concentration than quercetin. To investigate the lowest extractable concentration of rutin and quercetin, UV-vis absorbance was used. As shown in Fig. 9, for rutin and quercetin standard solutions, the lowest detectable concentrations were $0.3 \mu\text{g mL}^{-1}$ ($S/N = 5.0$) and $0.2 \mu\text{g mL}^{-1}$ ($S/N = 7.0$), respectively. When the detection was combined with the $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ extraction, the lowest detectable concentrations for rutin and quercetin were lowered to $0.003 \mu\text{g mL}^{-1}$ ($S/N = 12$) and $0.01 \mu\text{g mL}^{-1}$ ($S/N = 12$), respectively. The results indicated that the $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ were able to extract lower concentration of rutin as compared with other single *cis*-diol such as quercetin.

Effect of competing saccharides on the extraction of flavonoids by $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$

Sugars, *cis*-diol-containing compounds, are present in real samples such as in fruits, vegetables, herbaceous plants, tea, honey, coffee and, thus, their competing binding with boronic acids may result in reduced extraction capabilities of boronic acid-functionalized materials towards flavonoids. The $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ exhibited much higher binding affinity towards flavonoids as compared with their affinity towards saccharides

because flavonoids contain phenols while saccharides contains aliphatic alcohol. Thus, the $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ was very tolerant of the interference of competing saccharides. As shown in Fig. 10, even in the presence of a competing monosaccharide at 100-fold higher concentration, the Ru and Qu amount extracted by the $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ was 84–97% and 66–89% of that when no sugar was present, respectively, depending on the nature of the competing saccharide. Clearly, the binding of Ru to $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ is affected less than that of Qu to $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$ by the presence of the competing saccharide.

Binding pH

Binding pH is an important binding property of boronic acid-functionalized materials. As most commercially available boronic acid ligands are generally weak acids with a pK_a of 8–9, conventional boronic acid-functionalized nanomaterials require a basic binding pH. It is a common sense that the binding affinity of boronate affinity materials increased with increasing the pH. Therefore, the binding affinity is certainly better at alkaline pH than neutral pH or acidic pH. However, the basic pH is easy to oxidize the *cis*-diols of *cis*-diol-containing flavonoids. To address this issue, relatively low binding pH

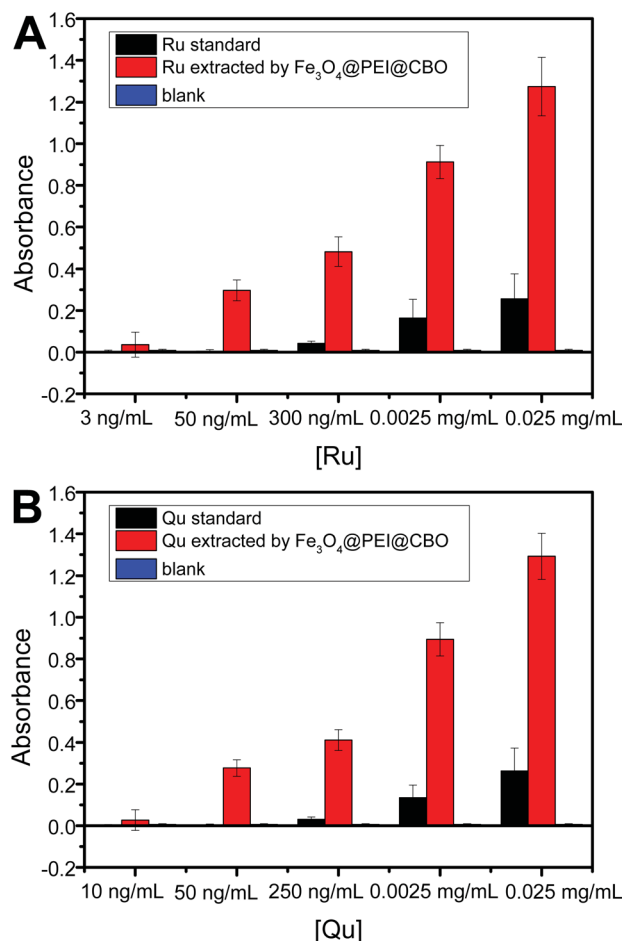

Fig. 9 The lowest extractable concentration of Ru (A) and Qu (B).

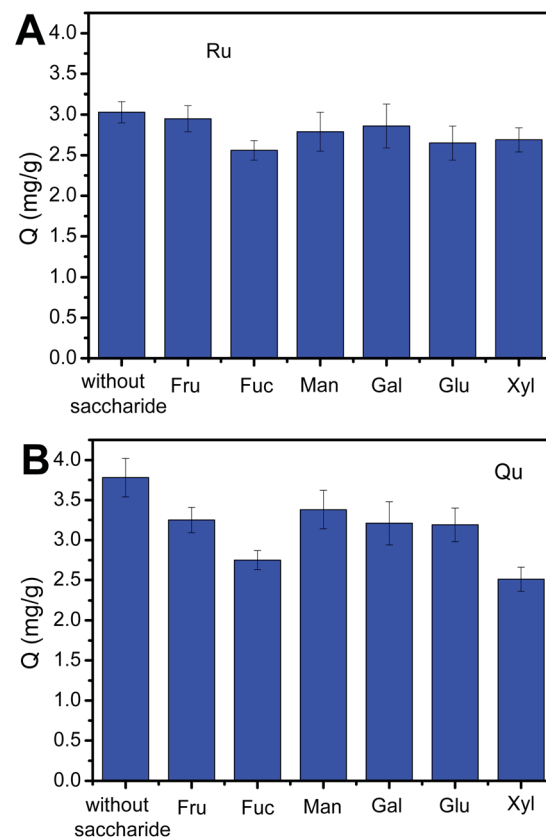

Fig. 10 Effect of competing saccharides on the Ru (A) and Qu (B) amount extracted by the $\text{Fe}_3\text{O}_4@\text{PEI}@\text{CBO}$. Samples: (A) $2 \mu\text{g mL}^{-1}$ Ru without or with 0.2 mg mL^{-1} saccharide; (B) $2 \mu\text{g mL}^{-1}$ Qu without or with 0.2 mg mL^{-1} saccharide, fructose (Fru), fucose (Fuc), mannose (Man), galactose (Gal), glucose (Glu), xylose (Xyl).

should be applied. Several boronic acid ligands with electron-withdrawing groups, such as DFFPBA and 3-carboxybenzoboroxole^{24,47} reduced the binding pH to neutral or acidic conditions. Thus, the prepared boronic acid-functionalized MNPs using 3-carboxybenzoboroxole as a ligand and PEI as a scaffold can provide a lower binding pH. As depicted in Fig. 11, the Fe₃O₄@PEI@CBO NPs exhibit high binding capacity and can well capture rutin or quercetin at pH ≥ 6.0. When the pH is higher than 6.0, the binding capacity of Fe₃O₄@PEI@CBO for rutin is lower than that for quercetin because one rutin molecule can occupy two boronic acid sites and one quercetin molecule can occupy only one boronic acid site. However, when the pH is lower than 5.0, the binding capacity of Fe₃O₄@PEI@CBO for rutin is higher than that for quercetin because binding affinity dominates binding capacity under lower pH conditions.

Reproducibility and reusability

The reproducibility of the obtained Fe₃O₄@PEI@CBO was investigated by using six batches of Fe₃O₄@PEI@CBO prepared on different days, and the measurements replicated three times in parallel. By calculation, the average *Q* of the total six batches of Fe₃O₄@PEI@CBO for Ru and Qu were 3.02 and 3.85 mg g⁻¹, and the relative standard deviations (RSD) were less than 5.1% (3.8%, 4.6%, 4.8%, 4.2%, and 5.1%) for Ru and less than 6.1% (5.3%, 4.5%, 6.1%, 5.8%, 4.9%, and 5.8%) for Qu. The results indicated that the reproducibility of the Fe₃O₄@PEI@CBO was satisfactory.

A stable adsorption performance is one of the most important properties of boronate affinity materials in real application. The Fe₃O₄@PEI@CBO could be reused after washing with acid solution. The adsorption–regeneration cycle was repeated ten times with the same Fe₃O₄@PEI@CBO to evaluate the stability of the Fe₃O₄@PEI@CBO. Fe₃O₄@PEI@CBO are very stable and adsorption capacity still maintain at almost a steady value of 92.6% of the first cycle after five adsorption–desorption cycles. That's, the Fe₃O₄@PEI@CBO could be well reused at least five times.

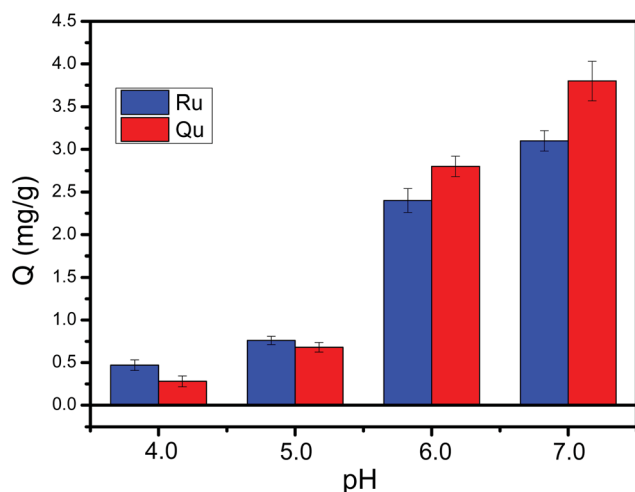

Fig. 11 pH on the effect of the binding capacity of Fe₃O₄@PEI@CBO towards Ru and Qu.

Conclusions

In this study, the high boronate avidity SNPs were prepared for the selective enrichment of trace glycoproteins. By using branched PEI as the scaffold for amplification of boronic acid sites and 3-carboxybenzoboroxole as the affinity ligand, high boronate avidity was obtained owing to PEI-assisted synergistic multivalent binding. The obtained binding constant is 10⁻⁷ M, which was the highest among already reported boronic acid-functionalized materials except MIPs. Besides, PEI-assisted synergistic effect can lead to lower binding pH. Due to the enhanced binding strength and the lower binding pH, the boronate avidity MNPs can be directly applied to selective enrichment of trace glycoproteins from real samples.
