5-Bromo-norborn-2-en-7-one derivatives as a carbon monoxide source for palladium catalyzed carbonylation reactions†

China M. Payne, , Kyulee Cho and David S. Larsen *

Norbornenone (**5b**), obtained from the reaction of 2,5-dimethyl-3,4-diphenylcyclopentadienone dimer (**3**) with bromomaleic anhydride (**4b**), provides an excellent base-triggered source of carbon monoxide for palladium-catalysed carbonylation reactions. Aminocarbonylation, ketoamide synthesis, and Suzuki–Miyaura reactions of aryl iodides carried out in a two-chamber reaction vessel gave good to excellent yields of carbonylated products.

Introduction

In order to avoid the use of carbon monoxide (CO) gas as a reactant in small scale reactions *in situ* generation from many sources including carbon dioxide,¹ aldehydes,² formates,³ and formamides^{4,5} such as *N*-formylsaccharin developed by Manabe and coworkers⁶ has been utilized. This circumvents the need for equipping small-scale chemical laboratories with cylinders of this highly toxic, odourless and colourless gas. In early work, the most commonly used CO sources were metal carbonyl compounds such as Mo(CO)₆ which proved useful, among others, for palladium catalysed aminocarbonylations and carbonylative Stille reactions of aryl halides.^{7–9} Recently, we have reported the development of norborneneone derivatives such as **oCOM-21** as physiologically relevant carbon monoxide releasing molecules. This water soluble Carbon Monoxide Releasing Molecule (CORM) undergoes an E1_{cB} elimination of HBr to a norbornadienone intermediate that spontaneously undergoes cheletropic release of CO in TRIS-sucrose buffer at pH 7.4 at 37 °C with a half-life of 19 minutes (Scheme 1).¹⁰ The rate of release is pH dependent and at higher pH the half-life is much reduced.

In parallel work to the development of these compounds, we viewed that simpler norborneneone constructs could provide readily accessible and bench stable CO sources for various palladium catalyzed carbonylation reactions as originally described by Heck,¹¹ Suzuki and coworkers¹² and Yamamoto.¹³ These would be an alternative to compounds such as silacarboxylic acids **1a–c** and 9-methyl-fluorene-9-carbonyl chloride (**2**) for CO generation for use in two-chamber reaction system such as that developed, and comprehensively studied, by the Skrydstrup group. They have demonstrated the utility of this

approach, using SilaCOgen **1b** and COgen **2** (along with their ¹³C and ¹⁴C labelled counterparts)¹⁴ in a number of palladium catalysed carbonylations including, aminocarbonylation,^{15,16} double carbonylations,¹⁶ Heck,^{17,18} and Suzuki–Miyaura reactions of both aryl iodides and bromides.^{19–21} CO release from COgen **2** is triggered in one chamber upon heating with a tri-*tert*-butylphosphine ligated palladium catalyst while that of silacarboxylic acids such as **1a** produces CO at ambient temperature upon treatment with a fluoride source. The synthesis of both COgen (**2**) and SilaCOgen (**1a**) requires carboxylation with CO₂ to install the carbonyl group (Fig. 1). More recently, this group have developed a tablet form of **2** that contains tri-*tert*-butylphosphonium tetrafluoroborate and Pd(OAc)₂ which allows convenient CO generation without the need for use of a glovebox for carbonylative transformations.²²

Herein, we report the development of readily accessible, stable norborneneone derivatives as efficient base-triggered CO donors as alternatives to **1** and **2** for palladium catalysed carbonylation reactions of aryl iodides using a two-chamber reaction system without the need for glovebox equipment.

Results and discussion

Our initial investigations into the viability of norborneneone based CORMs as suitable CO donors for various palladium catalysed carbonylation utilized **5a** as an *ex situ* CO surrogate.

Scheme 1 **oCOM-21**, a physiologically relevant CO source.¹⁰

Fig. 1 CO donor molecules developed by the Skrydstrup group.

2,5-Dimethyl-3,4-diphenylcyclopentadienone (**3**), readily available from the condensation of benzil and 3-pentanone,²³ exists as a reversible dimer, which reacted smoothly with *N*-phenyl-3-bromomaleimide (**4a**) to give cycloadduct **5a** in 71% yield as a bench stable solid (Scheme 2). The efficiency of **5a** as a CO donor was tested with the aminocarbonylation of *p*-iodoanisole (**6a**) and butylamine (**7**), catalysed by Pd₂(dba)₃ and using triethylamine as a base. This reaction gave *N*-butyl *p*-methoxybenzamide (**8a**) in 97% yield using a two-chamber reaction system similar to that developed by Skrydstrup *et al.*²⁴

Given the success of this reaction, the more readily accessible norbornadienone derivative **5b** was synthesized from commercially available bromomaleic anhydride (**4b**) and cyclopentadienone dimer **3** as an 8 : 1 mixture of the *endo* and *exo*-isomers in 96% yield, again as a bench stable solid. It was viewed that the anhydride moiety of **5b** would better facilitate the base induced elimination of HBr due to the electron withdrawing property of the anhydride compared to that of imide **5a**.

With the synthesis of cycloadduct **5b** complete, we investigated the scope of this compound as a CO source for palladium-catalysed carbonylation reactions. Initially, aminocarbonylations using a range of aryl iodides as the limiting reagent with both butylamine and morpholine as coupling partners were investigated (Scheme 3). In general, 1.5 equivalents of CO donor **5b** were dissolved in 1,4-dioxane and 2.0 equivalents of base were used to liberate CO in Chamber A. In all cases, complete conversion of **5b** into **9** was observed. Furthermore, in Chamber B high conversions of aryl iodide substrates into amides **8a–e** and **10a–e** were observed with isolated yields after column chromatography ranging from 72–99%, as detailed in Tables 1 and 2.

In addition to cycloadduct **5b**, a second CO source was investigated which produces a norbornadienone intermediate that spontaneously undergoes chelotropic loss of CO. A Diels–Alder reaction was carried out between cyclopentadienone

Scheme 2 Reaction of **3** and **4a** or **4b** to give corresponding cycloadduct **5a** or **5b**.

Scheme 3 General reaction scheme using **5b** as the CO source for aminocarbonylation reactions of aryl iodides **6a–e** and either *n*-butylamine (**7**) and morpholine (**11**) in 1,4-dioxane. Reagents and conditions: 80 or 100 °C, 20–25 h. (A) Et₃N (1.5 eq.), 1,4-dioxane. (B) Pd₂(dba)₃ (5 mol%), PPh₃ (10 mol%), Et₃N (2.3 eq.) 1,4-dioxane.

dimer **3** and diethyl acetylenedicarboxylate in the CO producing chamber (Scheme 4). On heating both chambers in 1,4-dioxane substituted benzene **12** (ref. 25) was produced in Chamber A in 91% yield. The aminocarbonylation reaction in Chamber B (see Table 1; Entries 1 and 2, note c) gave *N*-butyl-4-iodo- and *N*-butyl-4-nitro-benzamides (**8a** and **8b**) in 95 and 82% yields, respectively.

In order to show the scope of cycloadduct **5b** as a CO donor, other palladium catalysed carbonylation reactions were investigated. Following a 2006 report by Kondo *et al.* on room temperature double carbonylations,²⁶ the Skrydstrup group have successfully utilized both COgen and SilaCOgen as an *ex situ* CO sources for double carbonylation reactions.^{15,27} The reaction of iodoanisole (**6a**) and butylamine (**7**) with CO generated from three equivalents of **5b** in Chamber A gave doubly carbonylated α -ketoamide product **13** in 64% yield. This result demonstrated that cycloadduct **5b** could liberate CO at room temperature (Scheme 5).

Scheme 4 Reaction of **3** and diethyl acetylenedicarboxylate to give **12** and CO.

Scheme 5 The double carbonylation of *p*-iodoanisole (**6a**) and butylamine (**7**) using cycloadduct **5b** as a CO source. Chamber A: toluene, rt. (a) DBU (3.0 eq.), Chamber B: Pd₂(dba)₂ (5 mol%), [(tBu)₃PH] BF₄ (10 mol%), DBU (2.0 eq.), 64%.

Scheme 6 Synthesis of aromatic ketones using **5b** (3.0 eq.) and Et₃N (3.5 eq.) in 1,4-dioxane as the CO source from Chamber A for palladium-catalysed carbonylative Suzuki–Miyaura reactions. Reagents and conditions: 80 °C; Chamber A: **5b** (3.0 eq.), NEt₃ (3.5 eq.), dioxane. Chamber B: aryl iodides **6** (1 eq.), Pd₂(dba)₂ (2 mol%), K₂CO₃ (3.0 eq.), anisole.

Another example of widely utilized palladium catalysed carbonylation reactions is the well-known Suzuki–Miyaura carbonylation. This was first reported in 1998 following development of the cross coupling reaction of the same name.²⁸ A brief investigation into the optimization of reaction conditions for our system showed a ligand-free system could be used and a higher CO/Pd⁽⁰⁾ ratio was necessary when compared to the amino-carbonylation reaction. This was achieved by using three equivalents of CO donor in the CO releasing chamber (Scheme 6). With optimized reaction conditions in hand, a series of Suzuki–Miyaura carbonylation reactions were carried out with the goal of synthesizing fenofibrate – a biologically relevant example of an unsymmetrical biaryl ketone. Entry 4, Table 3 shows the synthesis of a model system that involved the synthesis of simpler aryl iodide component **6f** reacting with 4-chlorophenylboronic acid (**14b**) to give the corresponding biaryl ketone **15d** in 75% yield. In a similar

Fig. 2 3-Acyl indoles synthesised *via* Suzuki–Miyaura carbonylation reaction.

Scheme 7 Reaction of 3-iodo-1*H*-indole (**16**) with 2-morpholinoethyl methanesulfonate (**19**) to give iodoindole **21**. Reagents and conditions: DMF, NaH, 4 h, rt, 90%.

manner iodide **6g** and **14b** gave fenofibrate **15e** in an 80% yield (Entry 5, Table 3).

Recent literature has shown only a few examples of cannabimimetic indoles that have been synthesised *via* carbonylation reactions.^{29–31} The most relevant to this work involved a tandem C–H bond iodination and carbonylative Suzuki–Miyaura cross-coupling.³² However, their process used gaseous CO and additives such as pyridine and CsF to facilitate the reaction. Trial carbonylation reactions of 3-iodo-1*H*-indole (**16**) with phenylboronic acid (**14a**) and 2-naphthylboronic acid (**14c**) were carried out under the same conditions used for previous Suzuki–Miyaura carbonylations to give 3-acyl indoles (**17**) and (**18**) in moderate yields (Fig. 2).

Synthetic acylindole cannabinoids are commonly functionalized at the indole nitrogen with an ethylmorpholine side chain. Early work into the structure activity relationships of synthetic cannabinoids found that this substituent had optimal binding activity at the CB₁ receptor.³³

N-alkylation of 3-iodo-1*H*-indole (**16**) with mesylate **19** gave iodoindole **20** (Scheme 7) which was then subjected to Suzuki–Miyaura carbonylation with 4-methoxyphenylboronic acid (**14b**) and 2-naphthylboronic acid (**14c**), respectively under the conditions described in Scheme 6. The corresponding acylindoles **21** and **22** were obtained in moderate yields (Fig. 3).

Fig. 3 Synthetic cannabinoid 3-acyl indoles synthesised *via* Suzuki–Miyaura carbonylation reaction.

Conclusions

In conclusion, we have shown that readily synthesized norbornenones **5a** and **5b** are excellent alternatives to using CO gas for small scale carbonylation reactions using a two-chamber reaction system. CO release is triggered by organic bases such as triethylamine and DBU. With the latter base release is rapid even at room temperature which is essential for forming α -ketoamides *via* a double carbonylation reaction. Alternatively, CO gas can be generated by the thermally promoted Diels–Alder reaction of cyclopentadienone **4** and diethyl acetylenedicarboxylate which was also effective for aminocarbonylation reactions.

Experimental

Aminocarbonylation reactions

General procedure A: synthesis of secondary amides from aryl halides and primary amine (*n*-butylamine) using diethyl acetylenedicarboxylate as CO source. The two-chamber system, equipped with Teflon® coated magnetic stirrer bars, was loaded with all solid reagents. In Chamber A; diene dimer **3** (0.75 eq.). In Chamber B; Pd₂(dba)₃ (0.025 eq.) and PPh₃ (0.1 eq.). Then, all liquid reagents were added *via* syringe: to Chamber A: 1,4-dioxane (5 mL) and diethyl acetylenedicarboxylate (1.5 eq.); to Chamber B: 1,4-dioxane (4 mL), aryl halide **6** (1 eq.; aryl halides that were solids at room temperature were added with the catalyst and ligands), *n*-butylamine (**7**) (2.3 eq.) and Et₃N (2.3 eq.). The system was sealed with screwcaps fitted with silicon seal inserts. The two chamber system was heated in an oil bath at 80 °C with stirring, for 20 h. The reaction mixture was cooled to rt then the solvents in Chamber A and B were individually concentrated *in vacuo*. The crude material obtained was purified by silica gel column chromatography.

General procedure B: synthesis of secondary and tertiary amides from aryl halides and primary amine (*n*-butylamine) using cycloadduct **6b as the CO source.** The two-chamber system, equipped with Teflon® coated magnetic stirrer bars, was loaded with all solid reagents. In Chamber A; cycloadduct **5b** (1.5 eq.). In Chamber B; Pd₂(dba)₃ (0.025 eq.) and PPh₃ (0.1 eq.), the aryl halide (1 eq.), if solid. Then, all liquid reagents were added to Chamber B *via* syringe: aryl halide **6** (1 eq.) (if liquid), *n*-butylamine (2.3 eq.) and 1,4-dioxane (Chamber A: 5 mL, Chamber B: 4 mL). The system was cooled in an ice bath (with sodium chloride) and flushed with argon. Et₃N (2.3 eq.) was added to Chamber B *via* syringe, and the cap (fitted with a silicon seal insert) screwed in place. Et₃N (2.3 eq.) was also added to Chamber A *via* syringe, and the system was sealed. The two chamber system was heated in an oil bath at either 80 or 100 °C with stirring, for 20 h. The reaction mixture was cooled to rt then the solvent in Chamber B was concentrated *in vacuo*. The crude material obtained was purified by silica gel column chromatography.

Suzuki–Miyaura carbonylation

General procedure C: synthesis of unsymmetrical biaryl ketones using cycloadduct **6b as the CO source.** The two-

chamber system, equipped with Teflon® coated magnetic stirrer bars, was loaded with all solid reagents. In Chamber A; cycloadduct **5b** (3 eq.). In Chamber B; Pd₂(dba)₃ (0.025 eq.), K₂CO₃ (3 eq.), boronic acid **14** (1.5 eq.) and aryl halide **6** (1 eq.), if solid. Then, all liquid reagents were added to Chamber B *via* syringe: aryl halide (1 eq.) (if liquid), and anisole (5 mL). The system was cooled in an ice bath (with sodium chloride) and flushed with argon, and the cap (fitted with a silicon seal insert) screwed in place. 1,4-dioxane (5 mL) was added to Chamber A, *via* syringe followed by Et₃N (2.3 eq.) and the system was sealed. The two chamber system was heated in an oil bath at 80 °C with stirring, for 20 h. The reaction mixture was cooled to rt, and the solvent in Chamber B was concentrated *in vacuo*. The crude material obtained was purified by silica gel column chromatography.
