Cobalt sulfides/carbon nano hybrids: a novel biocatalyst for nonenzymatic glucose biofuel cells and biosensors†

Zihan Li,^a Gangyong Li,^a Zhongdong Wu,^b Shuqiang Jiao ^a and Zongqian Hu ^{*c}

Exploring high-performance electrocatalysts is of great importance in developing nonenzymatic biofuel cells. Hybrid nanostructures with transition metal compounds and carbon nanomaterials exhibit excellent electrocatalytic activity and have emerged as promising low-cost alternatives for various electrochemical reactions. Herein, we report cobalt sulfide/carbon nano hybrids *via* a facile synthesis, which have excellent electrocatalytic activity for glucose oxidation and oxygen reduction reaction. The nonenzymatic glucose biofuel cells equipped with cobalt sulfide/carbon nano hybrids deliver a high open circuit voltage of 0.72 V with a maximum open power density of 88 $\mu\text{W cm}^{-2}$, indicating that cobalt sulfide/carbon nano hybrids are high performance biocatalysts for bioenergy conversion.

1. Introduction

Enzymatic glucose biofuel cells are a special type of fuel cell that convert energetic biomass into electric energy through bio-electrochemical pathways using a bio-enzyme as a catalyst.^{1–5} During the anode reaction, glucose oxidase or glucose dehydrogenase is usually used for the oxidation of glucose,⁶ while laccase or bilirubin oxidase is adopted as the cathodic catalyst for the oxygen reduction reaction (ORR).^{4,7} In the past decade, a few glucose biofuel cells have been successfully implanted in organisms such as oranges,⁸ clams,⁹ snails¹⁰ and rats.^{11,12} However, the practical applications of glucose biofuel cells are limited due to the poor stability,¹³ rough immobilization technology¹⁴ and susceptibility to the operating environment of the enzymes.¹⁵

To overcome the drawbacks of the enzyme, some metal-based nanomaterials (*e.g.* precious metals,^{13,16} metal complexes¹⁷) have been used as the catalysts to replace the bio-enzyme to fabricate nonenzymatic glucose biofuel cells (NGBCs). However, most of the NGBCs use precious metals as cathodic or anodic catalysts.^{13,16,18} Although the high cost and scarcity of these precious metals severely limit their applications.^{19,20} In this regard, developing non-precious metal anodes and cathodes in NGBCs is highly challenging but imperative for practical applications. Currently, transition metals and their composites have received

wide attention, especially cobalt, due to its good biocompatibility, low cost and higher natural abundance compared with precious metals.^{21–23} Cobalt has been widely used as catalysts because of its loosely bound d electrons.²⁴ While cobalt sulfides have been investigated as overall water splitting²⁵ and carbon dioxide (CO₂) reduction²⁴ catalysts due to their excellent electrochemical activity among different transition metal chalcogenides.^{26–30} However, cobalt sulfides have still been seldomly reported as the dual electrode electrocatalysts of NGBCs. In addition, cobalt sulfides have low charge transport because of their poor electronic conductivity.²⁵ Thus, integrating cobalt sulfides with conducting carbon nanomaterials is an important strategy to increase their electroactive area and enhance the electronic conductivity.^{31–33}

In this work, we report a novel NGBC based on cobalt sulfides as dual electrode electrocatalysts. In the anode section, we designed a non-precious metal anode catalyst (Co₃S₄ and graphene hybrid, Co₃S₄-G) *via* a simple controlled method. The Co₃S₄-G sample showed an excellent glucose oxidation activity, high sensitivity (687.13 $\mu\text{A cm}^{-2} \text{mM}^{-1}$), low detection limit (0.4 μM), fast response and good selectivity toward the detection of glucose. Alternatively, we used cobalt sulfide and a carbon nanotube hybrid (Co_{1–x}S-CNT) as the cathode catalyst. The Co_{1–x}S-CNT performed at an onset potential of 0.01 V (*vs.* Hg/HgO), which was close to that of commercial Pt/C (0.025 V) and a positive shift (20 mV) in the half wave potentials compared to commercial Pt/C. As a result, an enhanced NGBC was achieved on the basis of high glucose oxidation and oxygen reduction performance.

2. Experimental

2.1. Material synthesis

2.1.1. Synthesis of graphene oxide (GO). GO was made according to our previous report with modifications.³ One gram of

† Electronic supplementary information (ESI) available. See DOI: 10.1039/c9ra06766c

graphite flakes (99.8%, Alfa Aesar) and 1 g of sodium nitrate (NaNO_3 , 99%, Sinopharm Chemical Reagent Co., Ltd) were mixed with 50 mL concentrated H_2SO_4 in a 250 mL round-bottom flask with an ice-water bath. After stirring for 30 min, 6 g of KMnO_4 was slowly added into the mixture and stirred for 6 h at 40 °C. Then, 100 mL of deionized water was slowly added into the mixture and gently stirred for 30 min at 90 °C. Afterward, H_2O_2 aqueous solution (30%, Sinopharm Chemical Reagent Co., Ltd) was added dropwise into the mixture until the color turned bright yellow. Finally, the mixture was centrifuged and washed thoroughly with 1 M HCl and deionized water. The as-prepared GO was freeze-dried.

2.1.2. Synthesis of the Co_3S_4 and graphene hybrid ($\text{Co}_3\text{S}_4\text{-G}$). 100 mg of GO was dispersed in 40 mL deionized water. Then 1.454 g of cobalt nitrate hexahydrate ($\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$, 98.5%, Sinopharm Chemical Reagent Co., Ltd) was added into the GO aqueous solution and stirred for 20 min. 2-Methylimidazole (2-mlm, 99%, Sinopharm Chemical Reagent Co., Ltd) was dispersed in another 60 mL deionized water and, after it completely dissolved, it was quickly added to the above mentioned mixture, and stirred for 30 min. The composite of Co-MOF and GO (denoted as Co-MOF-GO) was obtained after centrifugation and dried overnight at 60 °C. Then, Co-MOF-GO was mixed with sublimed sulfur (S, 99.5%, Sinopharm Chemical Reagent Co., Ltd) at a mass ratio of 1 : 3, then heated in a furnace filled with argon at 800 °C for 2 h (heating rate 5 °C min^{-1}) to obtain the $\text{Co}_{1-x}\text{S}/\text{Co}_9\text{S}_8$ and graphene hybrid (denoted as $\text{Co}_{1-x}\text{S}/\text{Co}_9\text{S}_8\text{-G}$). Finally, the $\text{Co}_{1-x}\text{S}/\text{Co}_9\text{S}_8\text{-G}$ powder was annealed in a muffle furnace at 300 °C for 3 h (heating rate 2 °C min^{-1}) to obtain $\text{Co}_3\text{S}_4\text{-G}$.

2.1.3. Synthesis of the Co_{1-x}S and carbon nanotube hybrid ($\text{Co}_{1-x}\text{S-CNT}$). 50 mg of carbon nanotube (CNT) and 300 mg of poly(vinylpyrrolidone) (PVP, K29-32, Sinopharm Chemical Reagent Co., Ltd) were dispersed in 50 mL methanol. 1.454 g of $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ and 3.28 g 2-mlm were both dissolved in 25 mL methanol. First, the solution of $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ was added into the solution of the CNT, and stirred for 20 min. And then, added the solution of 2-mlm, stirring for 2 h at room temperature. This was followed by centrifugation to obtain the composite of Co-MOF and CNT (denoted as Co-MOF-CNT). Then, Co-MOF-CNT was mixed with sublimed sulfur at a mass ratio of 1 : 3, and heated in a furnace filled with argon at 800 °C for 2 h (heating rate 5 °C min^{-1}) to obtain $\text{Co}_{1-x}\text{S-CNT}$.

2.2. Characterization

X-ray diffraction (XRD) measurements were performed by a PANalytical X'pert Pro X-ray diffractometer using $\text{Cu K}\alpha$ radiation ($\lambda = 1.5418 \text{ \AA}$). Raman spectra were obtained using a WITecCRM200 instrument with a 532 nm laser. X-ray photoelectron spectroscopy (XPS) analysis was recorded on a Thermo Scientific Escalab 250 spectrometer by using an Al $\text{K}\alpha$ X-ray source. The morphologies were characterized by a field emission scanning electron microscopy (FESEM, JSM-6701) and transmission electron microscopy (TEM, JEOL JEM-2100).

2.3. Electrochemical tests

2.3.1. Glucose oxidation reaction (GOR) test. Typically, 5 μL of 5 mg mL^{-1} $\text{Co}_3\text{S}_4\text{-G}$ suspension (dispersed in deionized water

and DMF at a volume ratio of 1 : 1) was cast on the surface of the pretreated glass carbon electrode (GCE, 3 mm in diameter) and dried in air (denoted as $\text{Co}_3\text{S}_4\text{-G/GCE}$). All the electrochemical measurements were carried out on a CHI 660E electrochemical analyzer (Shanghai, China) using a three-electrode system configuration with a 0.1 M KOH solution as the electrolyte, in which the above mentioned modified glass carbon was used as the working electrode, Pt foil (surface area: 1 cm^2) as the counter electrode and a Hg/HgO electrode as the reference electrode. Meanwhile, the solutions were deoxygenated with highly pure argon (99.99%) for at least 15 min before tests.

2.3.2. Oxygen reduction reaction (ORR) test. The electrochemical performance was recorded on a CHI 760E electrochemical workstation with a typical three-electrode cell. A Hg/HgO electrode full of 1 M KOH aqueous solution was used as the reference electrode, and a Pt wire was utilized as the counter electrode. 5 mg of the sample ($\text{Co}_{1-x}\text{S-CNT}$) and 16 μL of 5 wt% Nafion solution were dispersed into 1 mL of 3 : 1 v/v water/isopropanol mixed solution and then ultrasonicated for an hour to get a homogeneous suspension. 4 μL of this suspension (0.1 mg cm^{-2}) were dropped on a pre-treated glassy carbon rotating disk electrode (5 mm in diameter) and dried in air for use as the working electrode. The ORR activity was detected in O_2 -saturated 0.1 M KOH solution by using a rotating disk electrode (Pine Instruments). The linear sweep voltammograms (LSV) were recorded under a rotating speed of 1600 rpm at a scan rate of 5 mV s^{-1} .

For the rotating ring-disk electrode (RRDE) measurements, a rotating ring disk electrode with a glassy carbon disk and a Pt ring (Pine Instruments) was used as the working electrode. The disk electrode was scanned cathodically at a rate of 5 mV s^{-1} and the ring electrode's potential was constant at 1.5 V vs. RHE. The electron transfer number and % HO_2^- were determined by the equations:

$$n = 4 \times \frac{id}{id + ir/N} \quad (1)$$

$$\% \text{HO}_2^- = 200 \times \frac{ir/N}{id + ir/N} \quad (2)$$

where id is disk current, ir is ring current and N is current collection efficiency of the Pt ring, N was 0.37 from the instruction manual.

2.3.3. Full cell test. The full cell, made in house with an "H" type electrolytic pool, was separated by a Nafion 117 membrane. Ar-saturated 0.1 M glucose/0.1 M KOH solution was used as an anolyte in the anode chamber, and O_2 -saturated 0.04 M B-R (pH 5.0) solution was used as a catholyte in the cathode chamber. The $\text{Co}_3\text{S}_4\text{-G/GCE}$ was used as the anode electrode. 10 mg of $\text{Co}_{1-x}\text{S-CNT}$ or Pt/C (10%, Sigma Aldrich) was dispersed into 1 mL deionized water with adding 50 μL Nafion solution (5 wt%) and then ultrasonicated for an hour to get a homogeneous suspension. 200 μL of this suspension was loaded on a pre-treated carbon paper (2 cm^2) and dried in air for use as the cathode electrode. The power output of the full cell was recorded on a CHI 660E electrochemical workstation using LSV at a scan rate of 1 mV s^{-1} .

3. Results and discussion

The X-ray diffraction (XRD) patterns of the $\text{Co}_{1-x}\text{S}/\text{Co}_9\text{S}_8\text{-G}$ and $\text{Co}_3\text{S}_4\text{-G}$ hybrid are shown in Fig. 1a. For the $\text{Co}_{1-x}\text{S}/\text{Co}_9\text{S}_8\text{-G}$ hybrid, different diffraction peaks at $2\theta = 30.5^\circ, 35.1^\circ, 46.7^\circ, 54.2^\circ$ corresponding to the (100), (101), (102), (110) plane reflections of Co_{1-x}S (PDF#42-0826) and different diffraction peaks at $2\theta = 29.9^\circ, 47.7^\circ, 52.2^\circ$, corresponding to the (311), (511), (440) plane reflection of Co_9S_8 (PDF#75-2023) were present. The $\text{Co}_{1-x}\text{S}/\text{Co}_9\text{S}_8\text{-G}$, $\text{Co}_3\text{S}_4\text{-G}$ hybrid showed different diffraction peaks at $2\theta = 26.8^\circ, 31.5^\circ, 38.2^\circ, 50.4^\circ, 55.2^\circ$, corresponding to the (220), (311), (400), (511), (440) plane reflections of Co_3S_4 (PDF#74-0138), respectively. However, from the XRD patterns, it was observed that some impurity exists, indicating that there is possibly a small quantity of Co_3O_4 doped in the $\text{Co}_3\text{S}_4\text{-G}$ hybrid.

In order to confirm the chemical composition and valence of $\text{Co}_3\text{S}_4\text{-G}$, the electronic states of the Co and S phases were identified by X-ray photoelectron spectroscopy (XPS) measurements. Fig. 1b shows the XPS spectrum of $\text{Co}_3\text{S}_4\text{-G}$. The Co 2p core-level spectra showed two predominant peaks (Co 2p_{3/2} and Co 2p_{1/2}) with an energy separation of about 15.4 eV, as shown in Fig. 1c, indicating the presence of Co_3S_4 .³⁴ The high resolution of the S 2p spectrum (Fig. 1d) displayed peaks located at 163.7, 164.8 and 165.4 eV, which correspond to the S 2p_{3/2}, S 2p_{1/2} and S-C respectively. The peak at 168.8 eV identifies the presence of S-O binding, suggesting a partial oxidation of the Co_3S_4 shell on the surface.³⁵ Fig. S1a† shows that the O 1s spectrum was comprised of three components: oxygen atoms in the hydroxyl group, absorbed water, and O-Co bonds.³⁶ The N 1s and C 1s spectrum of $\text{Co}_3\text{S}_4\text{-G}$ are displayed in Fig. S1.†

Morphological and structural characterizations of the $\text{Co}_3\text{S}_4\text{-G}$ hybrid and its precursors were investigated by SEM and TEM. The SEM (Fig. 2a and b) and TEM (Fig. 2c) images clearly show the formation of Co_3S_4 particles with an average size of ~40 nm on graphene sheets. The graphene sheets can

not only induce higher porosity to facilitate ion diffusion but also inhibit the aggregation of the composites. As shown in Fig. 2d, the ordered lattice interplanar spacings were around 0.176 nm from a high-resolution TEM image of the (311) plane of Co_3S_4 .

The phase composition and morphology of the $\text{Co}_{1-x}\text{S}\text{-CNT}$ hybrid were characterized by the same method. XRD analyses are shown in Fig. 1e, and the sharp diffraction peaks from hexagonal Co_{1-x}S (PDF#42-0826) appear obviously, with different peaks at $2\theta = 30.5^\circ, 35.2^\circ, 46.7^\circ, 54.2^\circ$ corresponding to the (100), (101), (102), (110) plane reflections of Co_{1-x}S , respectively. XPS was used to further analyze the chemical composition and valence of the $\text{Co}_{1-x}\text{S}\text{-CNT}$ hybrid. As shown in Fig. 1g, the Co 2p_{1/2} and Co 2p_{3/2} spin-orbit coupling accompanied with weak satellite peaks can be deconvoluted from the Co 2p spectrum. The peaks located at 778.3 eV and 793.4 eV, 780.6 eV and 796.4 eV indicate the presence of Co^{3+} and Co^{2+} , respectively.³⁷ The S 2p spectrum was deconvoluted into S 2p_{1/2} and S 2p_{3/2} of S^{2-} in Co_{1-x}S at 161.7 eV and 163 eV as shown in Fig. 1h, and another peak at 168.6 eV corresponded to the oxidized S, possibly caused by oxidation in the air.³⁸ The C 1s spectrum is shown in Fig. S2.†

Morphological and structural characterizations of the $\text{Co}_{1-x}\text{S}\text{-CNT}$ hybrid was investigated by SEM and TEM. As shown in Fig. 2e and f, irregular polygon Co_{1-x}S particles were anchored on the surface of CNTs. The CNTs provide highly conductive pathways for electron transfer between the electrode material and the current collector to improve the overall electrical conductivity.³⁹ The TEM images shown in Fig. 2g confirm the close relationship between the Co_{1-x}S particles and CNTs, which is consistent with SEM characterization. The high-resolution TEM image is shown in Fig. 2h, where the crystal lattice fringe with an inter-planar distance of 0.196 nm matches well with the dominant XRD peak (101) of Co_{1-x}S . All the characterizations above indicate that the $\text{Co}_3\text{S}_4\text{-G}$ and $\text{Co}_{1-x}\text{S}\text{-CNT}$ hybrids were successfully synthesized.

To investigate the electrochemical catalytic activity of these cobalt sulfides based materials, the GOR and ORR performances were studied by a series of tests (described in the

Experimental section). Fig. 3a shows the CVs of $\text{Co}_3\text{S}_4\text{-G}$ modified GCE ($\text{Co}_3\text{S}_4\text{-G/GCE}$) and bare GCE in 0.1 M KOH in the presence of 5 mM glucose at a scan rate of 50 mV s^{-1} . The

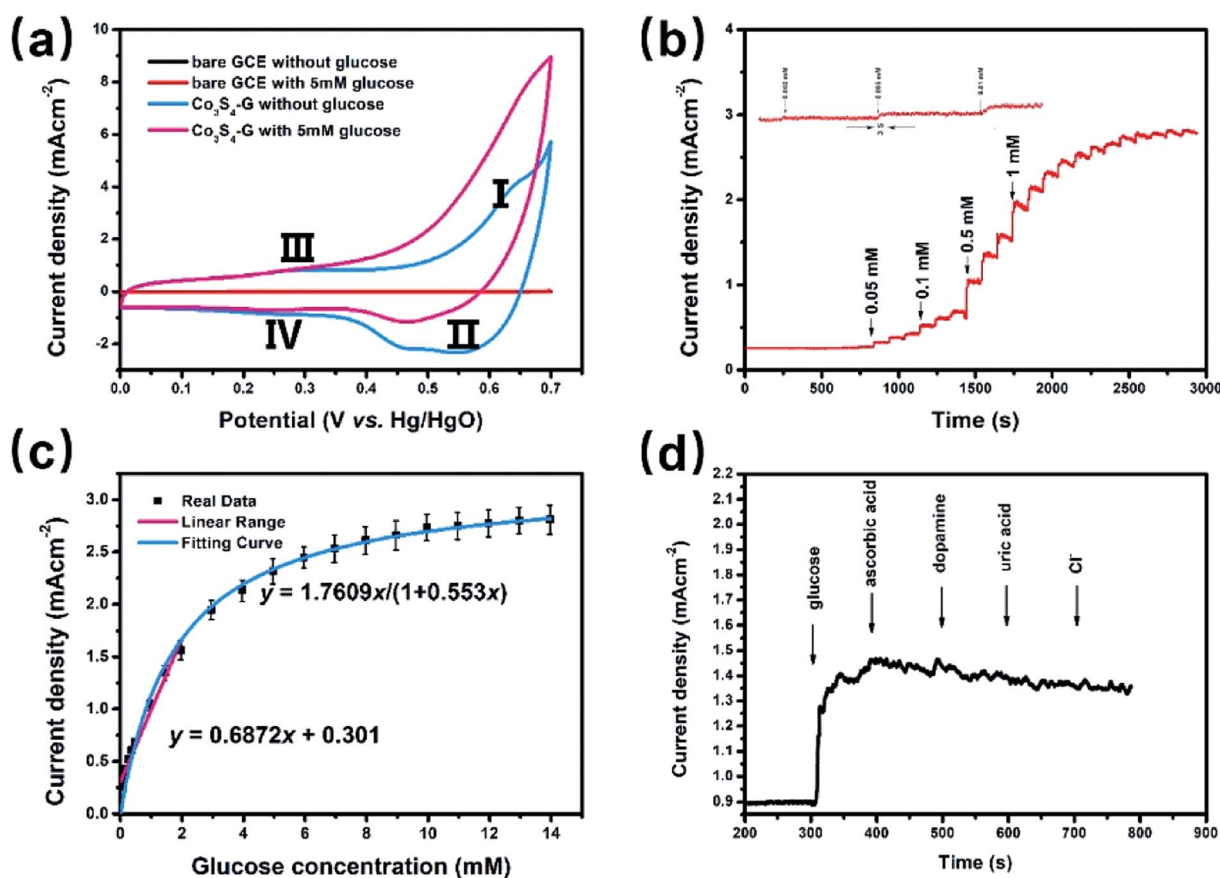

Fig. 3 $\text{Co}_3\text{S}_4\text{-G}$ hybrid as glucose oxidation catalysts. (a) CV curves of bare GCE and $\text{Co}_3\text{S}_4\text{-G}$ in 0.1 M KOH with 5 mM glucose or without glucose; (b) amperometric current response of a $\text{Co}_3\text{S}_4\text{-G}$ electrode in 0.1 M KOH with the continuous addition of glucose at 0.62 V; (c) calibration curve versus glucose concentration; (d) amperometric current response of a $\text{Co}_3\text{S}_4\text{-G}$ electrode in 0.1 M KOH with successive addition of glucose, ascorbic acid, dopamine, uric acid and Cl^- .

Co_{1-x}S-G displays two pairs of redox peaks, anodic peaks at around 0.62 V and 0.28 V, and cathodic peaks at around 0.55 V and 0.24 V. The pair of redox peaks I/II correspond to the reversible transition between Co³⁺ and Co⁴⁺, while peaks III/IV can be assigned to the conversion between Co²⁺ and Co³⁺.⁴⁰ Notably, an obvious increase of the anodic peak current was observed after the addition of glucose, especially at peak I. The electrooxidation process was mainly carried out by Co³⁺ and Co⁴⁺. Co²⁺ was initially oxidized to Co³⁺ and further to Co⁴⁺. Then, the electrooxidation of glucose occurred at the cost of Co⁴⁺ consumption, leading to an enhanced anodic current at peak I and a decrease in the cathodic peak current. The oxidation mechanism of Co₃S₄ as an active substance can be shown by the following reactions:⁴¹

The Co_{1-x}S-G performance can clearly be seen by the evident catalytic current peak about 4.12 mA cm⁻² in an intensity at 0.62 V (vs. Hg/HgO) in the presence of glucose, compared with that in the absence of glucose. In contrast, bare GCE exhibits a fairly weak response toward the oxidation of glucose. As shown in Fig. 3a, the current increase with the addition of glucose at peak I (Co³⁺ → Co⁴⁺) was much stronger than that at peak III (Co²⁺ → Co³⁺), which may suggest that the electrooxidation of glucose is mainly mediated by Co³⁺/Co⁴⁺, rather than Co²⁺/Co³⁺ in an alkaline solution. Therefore, the peak I potential (+0.62 V vs. Hg/HgO) was applied for the following amperometric detection. Fig. 3b shows the amperometric current response of Co₃S₄-G in 0.1 M KOH with the continuous addition of glucose at 0.62 V (vs. Hg/HgO). It had a fast amperometric response toward glucose and achieved steady state current density within 3 s. However, the baseline exhibited slight drift after multiple additions of glucose, which can be attributed to faster consumption of glucose than the diffusion or the adsorption of intermediates on the active sites.⁴² The fitting curve of this glucose sensor is shown in Fig. 3c. Langmuir isothermal theory was used to fit the curve, because the electrochemical oxidation of glucose on Co₃S₄-G is a surface catalytic reaction.⁴⁰ From the Langmuir isothermal theory, the concentration of glucose adsorbed on the catalyst surface (*C_{glucose S}*) can be expressed as:

$$C_{\text{glucose S}} = \frac{K_A C_{\text{glucose}} C_t}{1 + K_A C_{\text{glucose}}} \quad (6)$$

where, *K_A* is the adsorption equilibrium constant, *C_t* is the total molar concentration of active sites on Co₃S₄-G which is constant, and *C_{glucose}* is the concentration of glucose in the bulk electrolyte. Therefore, at a given applied potential, the current density response *J* from electrochemical oxidation of glucose is approximately proportional to *C_{glucose S}*, with a rate constant of *K_B*. Thus, *J* can be expressed as follows by defining a new constant *K* = *K_AK_BC_t*:

$$J = K_B C_{\text{glucose S}} = \frac{K_B K_A C_{\text{glucose}} C_t}{1 + K_A C_{\text{glucose}}} = \frac{K C_{\text{glucose}}}{1 + K_A C_{\text{glucose}}} \quad (7)$$

As shown in Fig. 3c, the *K* = 1.7609 and *K_A* = 0.553 of this equation can be calculated with a sufficient fitness (*R* = 0.985). Thus *J* can be expressed as follows:

$$J = \frac{1.76084 C_{\text{glucose}}}{1 + 0.55296 C_{\text{glucose}}} \quad (8)$$

At lower glucose concentrations, it exhibited a linear range from 0 to 2 mM, a sensitivity of 687.2 μA cm⁻² mM⁻¹ and a detection limit of 0.4 μM (S/N = 3) was achieved. These glucose oxidation results are superior to most of the reported electrochemical glucose sensors. The stability of Co₃S₄-G electrode was investigated by measuring its amperometric response for a long operational period. Fig. S5a† displays the amperometric response to 0.1 mM glucose within a 7 day period. After 7 days, the final amperometric response was approximately 97% of its original counterpart. As shown in Fig. S5b,† there is nearly no loss in the current signal over a period of 3500 s for 0.1 mM glucose in 0.1 M KOH at +0.62 V, suggesting excellent stability of the Co₃S₄-G electrode. Selectivity performance of Co₃S₄-G is shown in Fig. 3d. With the successive addition of glucose and other interferences in 0.1 M KOH, it can be seen that Co₃S₄-G has a remarkable response for glucose, superior to that of the interfering species. All the above results show that Co₃S₄-G is an excellent glucose electrochemical catalyst. According to the test above, the Co₃S₄-G hybrid can be considered as a high performance glucose catalyst.

The ORR activities of Co_{1-x}S-CNT were evaluated by rotating disk electrode (RDE) measurements in 0.1 M KOH solution. Fig. 4a shows the linear scan sweep voltammetry (LSV) curves of Co_{1-x}S-CNT, commercial Pt/C, Co_{1-x}S and CNTs at 1600 rpm, Co_{1-x}S-CNT exhibited an onset potential of 0.01 V (vs. Hg/HgO), which was close to that of the commercial Pt/C (0.025 V). Co_{1-x}S-CNT showed a large positive shift in the half wave potentials of Co_{1-x}S, CNTs and commercial Pt/C attribute to the synergistic effect of Co_{1-x}S and CNT. The Co_{1-x}S-CNT had a limiting current density of 5.15 mA cm⁻² at -0.8 V. However, this activity is still lower than that of Pt/C (5.7 mA cm⁻²). To quantitatively measure the ORR catalytic pathway of the Co_{1-x}S-CNT hybrid, the RRDE test was used to monitor the formation of peroxide species (HO₂⁻) during the ORR process (Fig. 4b). Fig. 4c shows the measured HO₂⁻ yield was below 9% for Co_{1-x}S-CNT and the corresponding electron transfer number (*n*) was above 3.85 over the potential range of -0.8 V to -0.2 V, suggesting that the Co_{1-x}S-CNT catalyst exhibits a dominant four-electron oxygen reduction process. Furthermore, after 30 000 s of long-term measurements of continuous ORR at -0.5 V in an O₂-saturated 0.1 M KOH at 900 rpm, the current density remained at about 85% of the Co_{1-x}S-CNT hybrid, whereas the attenuation for Pt/C was up to 31%. Considering the above analysis of the ORR activity test results,

Fig. 4 Co_{1-x}S-CNT hybrid as oxygen reduction catalysts. (a) LSV curves of commercial Pt/C, Co_{1-x}S-CNT, Co_{1-x}S and CNTs in O₂-saturated 0.1 M KOH at a sweep rate of 5 mV s⁻¹; (b) RRDE experiment results of Co_{1-x}S-CNT electrode for ORR in 0.1 M KOH at a scan rate of 5 mV s⁻¹; (c) corresponding percentage of peroxide in the total oxygen reduction products and the electron transfer number (*n*) calculated by the RRDE result; (d) chronoamperometric stability tests of the commercial Pt/C and Co_{1-x}S-CNT for 30000 s at -0.5 V (vs. Hg/HgO) in O₂-saturated 0.1 M KOH at 900 rpm.

the Co_{1-x}S-CNT hybrid had a high catalytic ORR activity and stability catalyst.

The H-type glucose fuel cell was fabricated using the Co₃S₄-G hybrid as the anode and the Co_{1-x}S-CNT as the

cathode catalyst. Fig. 5 shows the schematic of the H-type glucose fuel cell. Glucose was oxidized by Co₃S₄-G at the anode, and the electrons and protons generated by the glucose oxidation reaction were transferred from the anode

Fig. 5 Schematic and working mechanism of the designed glucose fuel cell.

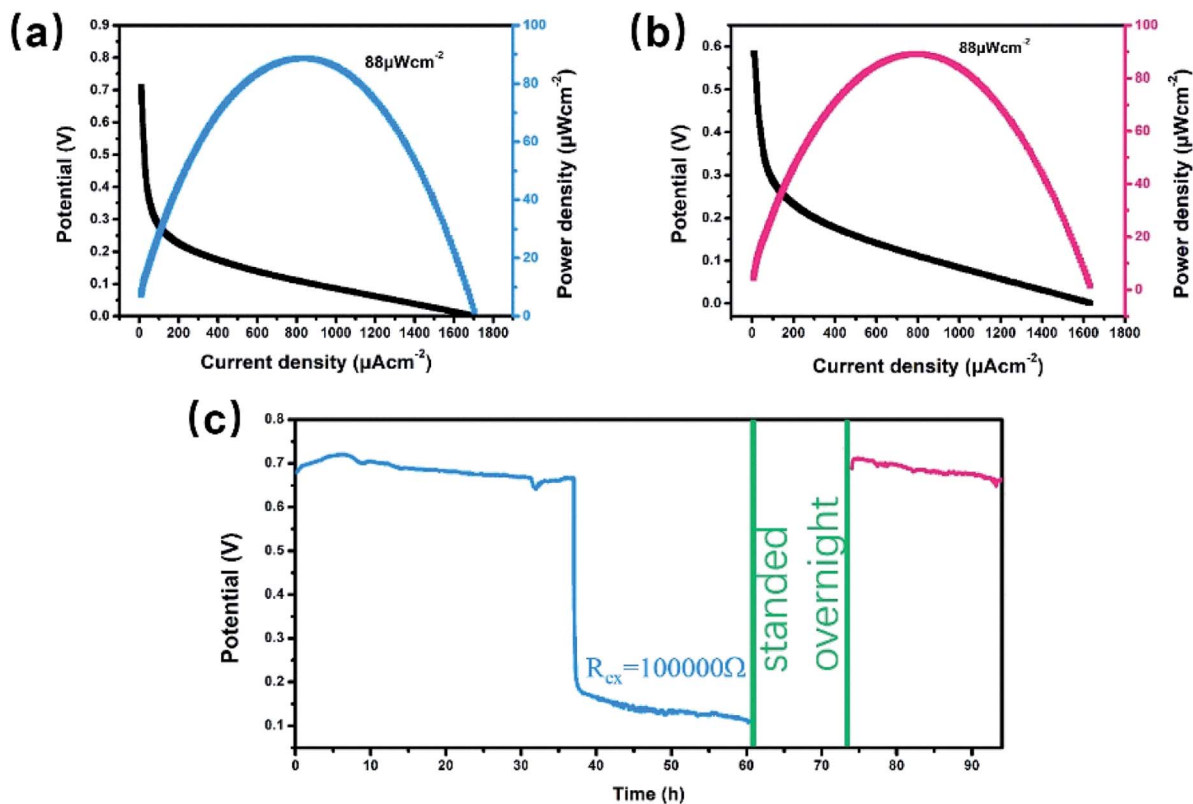

Fig. 6 H-type glucose fuel cell tests. (a) Polarization and power density curves of the $\text{Co}_3\text{S}_4\text{-G}/\text{Co}_{1-x}\text{S-CNT}_{(\text{a}||\text{c})}\text{-GFC}$; (b) power density and current density measured with long-time placed $\text{Co}_3\text{S}_4\text{-G}$ as the anode and long-time placed $\text{Co}_{1-x}\text{S-CNT}$ as the cathode; (c) output potential recorded for the $\text{Co}_3\text{S}_4\text{-G}/\text{Co}_{1-x}\text{S-CNT}_{(\text{a}||\text{c})}\text{-GFC}$.

to the cathode through an external circuit and internal solution, respectively. At the cathode, O_2 was reduced to H_2O by the action of $\text{Co}_{1-x}\text{S-CNT}$. As shown in Fig. 6a, the open circuit voltage (OCV) was 0.72 V, the maximum current density was $\sim 1700 \mu\text{A cm}^{-2}$, and the maximum power density was $88 \mu\text{W cm}^{-2}$. It had the same maximum power density, and a higher maximum current density ($\sim 650 \mu\text{A cm}^{-2}$), compared with Pt/C as the cathode catalyst (Fig. S6a†). A bare electrode fabricated glucose fuel cell is shown in Fig. S6b,† which exhibited a poor maximum current density ($\sim 4.2 \mu\text{A cm}^{-2}$) and maximum power density ($0.5 \mu\text{W cm}^{-2}$), proving that the excellent performance of the battery can be attributed to our catalyst ($\text{Co}_3\text{S}_4\text{-G}$ and $\text{Co}_{1-x}\text{S-CNT}$). Meanwhile, the stability was a major factor to assess the performance of the fuel cell. We used electrodes that were placed for a long time after modification (in the air for one week) to fabricate the glucose fuel cell. As shown in Fig. 6b, it exhibited the same power density output ($88 \mu\text{W cm}^{-2}$), proving that it was a stable catalyst. And long time discharge test was measured by land (CT2001A). As shown in Fig. 6c, the potential had a loss of 7% within the initial 36 h. Then loading an R_{ex} of 100k Ω , the voltage dropped to 0.5 V and then stabilized at ~ 0.2 V for 24 h. Subsequently, the battery stood overnight at room temperature, and its voltage recovered to ~ 0.7 V without external resistance. After 20 h, it held a voltage of ~ 0.66 V. The generated voltage gradually

decreased, which can be attributed to the glucose oxidizing to gluconolactone.^{15,43}

4. Conclusions

We successfully synthesized cobalt sulfides/carbon nano-hybrids and used them in NGBCs. The $\text{Co}_3\text{S}_4\text{-G}$ hybrid showed an excellent glucose electrooxidation activity, high sensitivity ($687.2 \mu\text{A cm}^{-2} \text{ mM}^{-1}$), low detection limit ($0.4 \mu\text{M}$), fast response, and good selectivity toward the detection of glucose, which can be used as an anodic catalyst for glucose biofuel cells. Meanwhile, the $\text{Co}_{1-x}\text{S-CNT}$ hybrid exhibited surprisingly high ORR activities, comparable to commercial Pt/C catalysts, and exceeded the stability of Pt/C. Therefore, $\text{Co}_{1-x}\text{S-CNT}$ can be used as a cathode catalyst for glucose biofuel cells. The as-designed glucose biofuel cell with $\text{Co}_3\text{S}_4\text{-G}$ as the anode catalyst and $\text{Co}_{1-x}\text{S-CNT}$ as the cathode catalyst had advantages of being low cost, was free of enzymes, had a high open circuit voltage of 0.72 V, a maximum open power density of $88 \mu\text{W cm}^{-2}$, a maximum current density was $\sim 1700 \mu\text{A cm}^{-2}$ and long-term stability. The voltage even stabilized at ~ 0.2 V for 24 h with loading an R_{ex} of 100k Ω , and its voltage can recover to ~ 0.7 V without external resistance. Our findings provide a new direction for the rational design or modification of dual electrode catalysts of NBGCs.
