# Three dimensional coupled reaction–diffusion modeling of calcium and inositol 1,4,5-trisphosphate dynamics in cardiomyocytes

 Nisha Singh \* and Neeru Adlakha

Nanoparticles have shown great promise in improving cancer treatment efficacy by changing the intracellular calcium level through activation of intracellular mechanisms. One of the mechanisms of the killing of the cancerous cell by a nanoparticle is through elevation of the intracellular calcium level. Evidence accumulated over the past decade indicates a pivotal role for the IP<sub>3</sub> receptor mediated Ca<sup>2+</sup> release in the regulation of the cytosolic and the nuclear Ca<sup>2+</sup> signals. There have been various studies done suggesting the role of IP<sub>3</sub> receptors (IP<sub>3</sub>R) and IP<sub>3</sub> production and degradation in cardiomyocytes. In the present work, we have proposed a three-dimensional unsteady-state mathematical model to describe the mechanism of cardiomyocytes which focuses on evaluation of various parameters that affect these coupled dynamics and elevate the cytosolic calcium concentration which can be helpful to search for novel therapies to cure these malignancies by targeting the complex calcium signaling process in cardiomyocytes. Our study suggests that there are other factors involved in this signaling which can increase the calcium level, which can help in finding treatment for cancer. The cytosolic calcium level may be controlled by IP<sub>3</sub> signaling, *leak*, source influx of calcium ( $\sigma$ ) and maximum production of IP<sub>3</sub> ( $V_p$ ). We believe that the proposed model suggests new insight into finding treatment for cancer in cardiomyocytes through elevation of the cytosolic Ca<sup>2+</sup> concentration by various parameters like *leak*,  $\sigma$ ,  $V_p$  and especially by other complex cell signaling dynamics, namely IP<sub>3</sub> dynamics.

## 1 Introduction

The emerging field of nanomedicine aims to diagnose and treat various diseases with nanostructures. The design of such nanosystems for imaging and therapeutic applications requires a thorough understanding of the interactions between nanoparticles and biological systems. Cancer represents the 2nd largest cause of death in the United States, and one out of eight women is estimated to develop invasive breast cancer in her lifetime.<sup>1</sup> Nanoparticles have shown great promise in improving cancer treatment efficacy while reducing toxicity and treatment side effects.<sup>2</sup> Different nanoparticles can change the intracellular calcium level through activation of intracellular machinery. In cancer therapy, nanoparticles are used to kill the malignant cells.<sup>3</sup> One of the mechanisms of the killing of the cancerous cell by nanoparticles is through elevation of the intracellular calcium level. One study reported that after 48 hours of nanoparticle treatment, the cytosolic calcium level increases 1.8 times in adenocarcinoma cells.<sup>4</sup>

Also, some attempts have been reported in the literature, for other different cells like hepatocytes,<sup>5</sup> neurons,<sup>6</sup> astrocytes,<sup>7,8</sup> fibroblasts,<sup>9</sup> pancreatic acinar cells<sup>10</sup> and oocytes,<sup>11</sup> to model the

calcium diffusion and regulation in the presence of time-dependent influx for the smooth muscle cell to study the magnitude, and spatial and temporal characteristics of calcium transients in restricted diffusion spaces between the plasma membrane and intracellular organelles.<sup>12</sup> Gregory D. Smith *et al.*<sup>13</sup> proposed a simple numerical model of calcium spark formation and detection in cardiomyocytes. According to their model, the elementary events of excitation–contraction coupling in the heart muscle are Ca<sup>2+</sup> sparks, which arise from one or more ryanodine receptors in the endoplasmic reticulum (ER). Backx *et al.*<sup>14</sup> constructed a model of propagating calcium-induced calcium release mediated by calcium diffusion in cardiomyocytes. The model was used to evaluate whether propagation of calcium transients and the range of propagation velocities observed experimentally (0.05–15 mm s<sup>−1</sup>) could be predicted. Y. Hamam *et al.*<sup>15</sup> proposed a model for calcium dynamics in cardiomyocytes. After the identification of the endoplasmic reticulum parameters, the SERCA pump and ryanodine channels activities, they made a comparison between experimental and calculated responses.

Consequently, it is of great interest to determine the mechanisms involved in these dynamics. In many cell types, these signaling processes depend on the inositol 1,4,5-trisphosphate (IP<sub>3</sub>) signaling.<sup>16–20</sup> For both atrial and ventricular cells, a role for the cytosolic IP<sub>3</sub> has been reported for the modulation of the

cytosolic  $\text{Ca}^{2+}$  transients in a variety of animal models.<sup>21–25</sup>  $\text{IP}_3\text{R}$  channel activity, with type-2  $\text{IP}_3\text{Rs}$  as the most prevalent isoform in cardiomyocytes, depends on  $\text{IP}_3$  concentration and  $\text{Ca}^{2+}$  concentration.<sup>23,26,27</sup> By the hydrolysis of phosphatidylinositol 4,5-bisphosphate ( $\text{PIP}_2$ ) by phospholipase C (PLC), two distinct second messengers, diacylglycerol and  $\text{IP}_3$ , are produced that diffuse through the cytoplasm and bind to and open  $\text{IP}_3$  receptors ( $\text{IP}_3\text{Rs}$ ) on the endoplasmic reticulum (ER) membrane, leading to the release of  $\text{Ca}^{2+}$  from the ER. The released  $\text{Ca}^{2+}$  is then sent back into the ER by pumps like the SERCA pump in cardiomyocytes.<sup>28</sup> Recently, Li *et al.*<sup>29</sup> also uncaged  $\text{IP}_3$  in cell cytoplasm from 2.1 to 5.3 nm AuNP-coated liposomes to activate cell signaling. They encapsulated  $\text{IP}_3$  in the liposome complex which then binds with the  $\text{IP}_3\text{R}$ . The binding event then causes  $\text{Ca}^{2+}$  release from the endoplasmic reticulum (ER) into the cytosol. Also, El-Sayed *et al.*<sup>30</sup> demonstrated that AuNPs with integrin-targeting properties could inhibit cancer cell migration through affecting cytoskeletal proteins. Furthermore, the highest increase in the calcium signal was observed, and the calcium response was likely due to the inflow of  $\text{Ca}^{2+}$  as well as intracellular signaling *via* the  $\text{IP}_3$  pathway.

For these reasons, although experimental methods<sup>17,31,32</sup> are being developed to measure  $[\text{IP}_3]$  directly, the question of the underlying oscillatory mechanism often remains unresolved. Many investigations on calcium dynamics in cardiomyocytes have not included the role of ryanodine receptors (RyR) and  $\text{IP}_3\text{R}$ .<sup>33–36</sup> whereas there are various investigations to understand the role of ryanodine receptors (RyR) in cardiomyocytes<sup>37–39</sup> but the importance of  $\text{IP}_3$  dynamics in  $\text{Ca}^{2+}$  in the cardiomyocyte is less explored. But there are pieces of literature<sup>40–42</sup> that suggest the impact of  $\text{IP}_3$  signaling on  $\text{Ca}^{2+}$  signaling in other cells. Also, there are few works showing the important role of  $\text{IP}_3$  signaling in  $\text{Ca}^{2+}$  signaling in the cardiomyocyte.<sup>26,28,43</sup> Motivated by the above and the intriguing possibility of cancer treatment with nanoparticles by elevation of the cytosolic calcium level, we have explored another biological factor inside the cardiomyocyte,  $\text{IP}_3$ , which strongly influences the cytosolic calcium ions concentrations. Earlier we have developed one<sup>44–46</sup> and two dimensional models<sup>47</sup> for the coupled dynamics but to make the study more realistic and have better insights into various processes involved in calcium regulation it is necessary to develop a model in a three-dimensional cylindrical-shaped cardiomyocyte. In this paper, an attempt has been made in this direction to propose a three-dimensional model to study spatiotemporal calcium and  $\text{IP}_3$  distribution in cardiomyocytes involving various parameters and their role in controlling calcium concentration in the cytosol for the better understanding and exploring of various treatments for cancer.

## 2 Methods

### 2.1 The mathematical model

Experimental investigations have been reported in the literature for interdependent  $\text{Ca}^{2+}$  and  $\text{IP}_3$  dynamics in oocytes.<sup>48</sup> Also, few works have been reported for interdependent  $\text{Ca}^{2+}$  and  $\text{IP}_3$

dynamics in cardiomyocytes. However, elementary  $\text{Ca}^{2+}$  release events and functional properties of  $\text{IP}_3$  are available in the literature.<sup>17,49,50</sup>

Apart from this, the reaction–diffusion equations for  $\text{Ca}^{2+}$  and  $\text{IP}_3$  dynamics are available in the literature.<sup>48</sup> Thus, the functional properties of  $\text{IP}_3$  release and the dynamics with  $\text{Ca}^{2+}$  in cardiomyocytes can be used as a basis to develop a coupled model of  $\text{Ca}^{2+}$  and  $\text{IP}_3$  dynamics in a cell. This coupling will be based on the relationships between the processes of  $\text{Ca}^{2+}$  and  $\text{IP}_3$  dynamics in a cell. In the present study the relationship between reaction–diffusion of  $\text{Ca}^{2+}$ , as well as  $\text{IP}_3$ , has been explored to propose a coupled model for  $\text{Ca}^{2+}$  and  $\text{IP}_3$  in cardiomyocytes (Fig. 1).

The model incorporates three mechanisms for  $\text{Ca}^{2+}$  release and reuptake: the  $\text{IP}_3$  receptor/ $\text{Ca}^{2+}$  channel, a small leak to maintain resting  $\text{Ca}^{2+}$  levels and SERCA pumps. The reaction–diffusion equations for  $\text{Ca}^{2+}$  and  $\text{IP}_3$  are given by,<sup>48</sup>

$$\frac{\partial [\text{Ca}^{2+}]_C}{\partial t} = D_C \nabla^2 [\text{Ca}^{2+}]_C + \frac{J_{\text{IPR}} - J_{\text{SP}} + J_{\text{Le}}}{F_C}, \quad (1)$$

$$\frac{\partial [\text{Ca}^{2+}]_E}{\partial t} = D_E \nabla^2 [\text{Ca}^{2+}]_E - \frac{J_{\text{IPR}} - J_{\text{SP}} + J_{\text{Le}}}{F_E}, \quad (2)$$

$$\frac{\partial [\text{IP}_3]}{\partial t} = D_I \nabla^2 [\text{IP}_3] + \frac{J_P - \lambda(J_K + J_{\text{PP}})}{F_C}, \quad (3)$$

where  $[\text{Ca}^{2+}]_C$  and  $[\text{Ca}^{2+}]_E$  are the concentrations of  $\text{Ca}^{2+}$  in the cytosol and ER, respectively.  $D_C$  and  $D_E$  are the diffusion coefficients of  $\text{Ca}^{2+}$  in the cytosol and ER. Also,  $D_I$  is the diffusion coefficient of  $\text{IP}_3$ .  $J_P$ ,  $J_K$  and  $J_{\text{PP}}$  are fluxes of  $\text{IP}_3$  production, Kinase and Phosphatase respectively in terms of total cell volume. All the flux terms are given by,<sup>48</sup>

$$J_{\text{IPR}} = V_{\text{IPR}} d^3 e^3 ([\text{Ca}^{2+}]_E - [\text{Ca}^{2+}]_C), \quad (4)$$

$$J_{\text{Le}} = V_{\text{Le}} ([\text{Ca}^{2+}]_E - [\text{Ca}^{2+}]_C), \quad (5)$$

$$J_{\text{SP}} = V_{\text{SP}} \frac{[\text{Ca}^{2+}]_C^2}{K_{\text{SP}}^2 + [\text{Ca}^{2+}]_C^2}, \quad (6)$$

In this formulation,  $F_C$  and  $F_E$  are the volume fractions, relative to total cell volume, of the cytosol and ER, respectively (with  $F_C + F_E = 1$ ), so the fluxes are also in terms of total cell volume.  $\text{IP}_3$  receptor dynamics are treated using the Li–Rinzel simplification of the eight-state De Young–Keizer model. In both formulations, the  $\text{IP}_3$  receptor is comprised of four identical subunits, each of which can bind an  $\text{IP}_3$ , an activating  $\text{Ca}^{2+}$ , and an inactivating  $\text{Ca}^{2+}$ , with the conducting state corresponding to any three of the subunits having  $\text{IP}_3$  and activating  $\text{Ca}^{2+}$  bound.<sup>48</sup>

$$J_P = V_P \frac{[\text{Ca}^{2+}]_C^2}{[\text{Ca}^{2+}]_C^2 + K_P^2}, \quad (7)$$

**Fig. 1** Schematic representation of the  $\text{Ca}^{2+}$  and  $\text{IP}_3$  dynamics model. In this model, various fluxes are involved such as  $\text{Ca}^{2+}$  is released from the ER via the  $\text{IP}_3$  receptor ( $J_{\text{IP}_3\text{R}}$ ), and reuptake occurs via SERCA ATPase pumps ( $J_{\text{SP}}$ ). A leak is used to maintain basal  $\text{Ca}^{2+}$  levels ( $J_{\text{Le}}$ ).  $\text{IP}_3$  is produced at the ER membrane via  $\text{Ca}^{2+}$ -dependent activation of PLC ( $J_{\text{P}}$ ). The terms responsible for  $\text{IP}_3$  degradation are these two fluxes  $J_{\text{Pp}}$  (Phosphatase) and  $J_{\text{K}}$  (Kinase).

$$J_{\text{K}} = (1 - \theta') V_{\text{a}} \frac{[\text{IP}_3]}{[\text{IP}_3] + 2.5} + \theta' V_{\text{b}} \frac{[\text{IP}_3]}{[\text{IP}_3] + 0.5}, \quad (8)$$

and

$$J_{\text{Pp}} = V_{\text{Pp}} \frac{[\text{IP}_3]}{[\text{IP}_3] + 30}, \quad (9)$$

The  $\text{Ca}^{2+}$  dependence of the 3-kinase degradation pathway is described by a Hill function,<sup>48</sup>

$$\theta' = \frac{[\text{Ca}^{2+}]}{[\text{Ca}^{2+}] + 0.39}. \quad (10)$$

The Li-Rinzel model, however, utilizes time scale arguments to eliminate two of the three binding reactions, replacing them with the equilibrium equation,<sup>48</sup>

$$d = \frac{[\text{IP}_3]}{[\text{IP}_3] + K_{\text{IP}_3}} \frac{[\text{Ca}^{2+}]_{\text{C}}}{[\text{Ca}^{2+}]_{\text{C}} + K_{\text{At}}}. \quad (11)$$

The variable  $e$  represents the fraction of subunits not yet inactivated by  $\text{Ca}^{2+}$  given by,<sup>48</sup>

$$\frac{de}{dt} = \frac{e_{\infty} - e}{\tau}, \quad (12)$$

where

$$e_{\infty} = \frac{K_{\text{In}}}{K_{\text{In}} + [\text{Ca}^{2+}]_{\text{C}}}, \quad (13)$$

is the equilibrium value, and  $\tau$  is the inactivation time scale. The analysis of the complete model is not possible using basic phase plane techniques. However, in a whole-cell model (*i.e.* where the diffusion terms are eliminated), the  $[\text{Ca}^{2+}]_{\text{E}}$  equation can be eliminated using the conservation relation for the total cellular  $\text{Ca}^{2+}$  concentration,<sup>48</sup>

$$[\text{Ca}^{2+}]_{\text{T}} = F_{\text{C}}[\text{Ca}^{2+}]_{\text{C}} + F_{\text{E}}[\text{Ca}^{2+}]_{\text{E}}. \quad (14)$$

The  $e$  nullcline is the surface  $e = e_{\infty}$ , which after substitution is,<sup>48</sup>

$$e = \frac{K_{\text{In}}}{K_{\text{In}} + [\text{Ca}^{2+}]_{\text{C}}}, \quad (15)$$

a relatively simple, monotonically decreasing function of  $\text{Ca}^{2+}$ . This allows the model to be reduced to the three variables  $[\text{Ca}^{2+}]_{\text{C}}$ ,  $[\text{IP}_3]$ , and  $e$ .<sup>48</sup> This model has been employed to perform a numerical study of  $\text{Ca}^{2+}$  and  $\text{IP}_3$  dynamics in cardiomyocytes. The calcium diffusion and  $\text{IP}_3$  diffusion in cardiomyocytes for a three-dimensional unsteady-state case can be rewritten as,

$$\frac{\partial [\text{Ca}^{2+}]_{\text{C}}}{\partial t} = D_{\text{C}} \left( \frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial [\text{Ca}^{2+}]_{\text{C}}}{\partial r} \right) + \frac{1}{r} \frac{\partial}{\partial \theta} \left( \frac{1}{r} \frac{\partial [\text{Ca}^{2+}]_{\text{C}}}{\partial \theta} \right) + \frac{\partial^2 [\text{Ca}^{2+}]_{\text{C}}}{\partial z^2} \right) + \frac{J_{\text{IP}_3\text{R}} - J_{\text{SP}} + J_{\text{Le}}}{F_{\text{C}}}, \quad (16)$$

$$\frac{\partial [\text{IP}_3]}{\partial t} = D_{\text{I}} \left( \frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial [\text{IP}_3]}{\partial r} \right) + \frac{1}{r} \frac{\partial}{\partial \theta} \left( \frac{1}{r} \frac{\partial [\text{IP}_3]}{\partial \theta} \right) + \frac{\partial^2 [\text{Ca}^{2+}]_{\text{C}}}{\partial z^2} \right) + \frac{J_{\text{P}} - \gamma(J_{\text{K}} + J_{\text{Pp}})}{F_{\text{C}}}, \quad (17)$$

Fig. 2 Discretization of the cytosol of the cell, where the yellow point at the top (at  $r = 4$ ,  $\theta = \pi$ ,  $z = 2$ ) and the green point at the bottom (at  $r = 4$ ,  $\theta = 0$ ,  $z = 2$ ) denote the point sources of  $\text{Ca}^{2+}$  and  $\text{IP}_3$ , respectively.

The height of the cardiomyocyte is  $100 \mu\text{m}$  and width of the cytosol of the cardiomyocyte is  $8 \mu\text{m}$ . Therefore, it is assumed that  $0 \leq r \leq 4 \mu\text{m}$ ,  $0 \leq \theta \leq 2\pi$ ,  $0 \leq z \leq 4$ , where  $z = 0$  means  $0 \mu\text{m}$ ,  $z = 1$  means  $25 \mu\text{m}$ ,  $z = 2$  means  $50 \mu\text{m}$ ,  $z = 3$  means  $75 \mu\text{m}$  and  $z = 4$  means  $100 \mu\text{m}$ . The three-dimensional finite difference discretization of the cardiomyocyte is shown in Fig. 2.

The initial and boundary conditions governing the  $\text{Ca}^{2+}$  and  $\text{IP}_3$  diffusion processes are given by,<sup>34,51,52</sup>

**(i) Initial condition**

$$[\text{Ca}^{2+}]_{\text{C},r,\theta,z,t=0} = 0.1 \mu\text{M}, \quad (18)$$

$$[\text{IP}_3]_{r,\theta,z,t=0} = 0.16 \mu\text{M}. \quad (19)$$

**(ii) Boundary condition**

Point sources of calcium and  $\text{IP}_3$  are assumed at  $r = 4$ ,  $\theta = \pi$ ,  $z = 2$  and  $r = 4$ ,  $\theta = 0$ ,  $z = 2$  respectively. Thus, the boundary conditions at  $t > 0$  are given below. Here, the source influx can be expressed as

$$\lim_{r \rightarrow 4, \theta \rightarrow \pi, z \rightarrow 2} \left( -2\pi r D_{\text{C}} \frac{\partial [\text{Ca}^{2+}]_{\text{C}}}{\partial r} \right) = \sigma, \quad (20)$$

here, an influx of free  $\text{Ca}^{2+}$  is taken at the rate  $\sigma$  by Faraday's law,<sup>13</sup>

$$\sigma = \frac{I}{zF}, \quad (21)$$

where  $I$  is the amplitude of the element of  $\text{Ca}^{2+}$  release,  $F$  is Faraday's constant and  $z$  is the valence of the  $\text{Ca}^{2+}$  ion.

$$\begin{aligned} \lim_{r \rightarrow 4, \theta \rightarrow 0, z \rightarrow 2} [\text{IP}_3] &= 0.1882(t)^6 + 1.3121(t)^5 + 3.5391(t)^4 \\ &+ 4.5312(t)^3 + 2.5893(t)^2 + 0.3648(t) \\ &+ 0.1691 \leq 3. \end{aligned} \quad (22)$$

At the rest of the boundary points there is no flux, thus the boundary conditions are as follows,

$$\frac{\partial [\text{Ca}^{2+}]_{\text{C}}}{\partial r} \Big|_{r=4, \theta \neq \{0, \pi\}, z \rightarrow 2} = 0, \quad (23)$$

$$\frac{\partial [\text{Ca}^{2+}]_{\text{C}}}{\partial r} \Big|_{r \rightarrow 4, \theta \neq 0, z \rightarrow \{1, 3\}} = 0, \quad (24)$$

$$\frac{\partial [\text{IP}_3]}{\partial r} \Big|_{r \rightarrow 4, \theta \neq \{0, \pi\}, z \rightarrow 2} = 0, \quad (25)$$

$$\frac{\partial [\text{IP}_3]}{\partial r} \Big|_{r \rightarrow 4, \theta \neq \pi, z \rightarrow \{1, 3\}} = 0. \quad (26)$$

It is assumed that at the boundary far away from the source of calcium, the calcium concentration is maintained at background calcium concentration which can be written as follows,

$$\lim_{r \rightarrow 4, \theta \rightarrow 0, 1 \leq z \leq 3} [\text{Ca}^{2+}]_{\text{C}} = 0.1 \mu\text{M}, \quad (27)$$

$$\lim_{0 \leq r \leq 4, 0 \leq \theta \leq 2\pi, z \rightarrow \{0, 4\}} [\text{Ca}^{2+}]_{\text{C}} = 0.1 \mu\text{M}. \quad (28)$$

It is assumed that at the boundary far away from the source of  $\text{IP}_3$ , the  $\text{IP}_3$  concentration is maintained at background concentration which can be written as follows,

$$\lim_{r \rightarrow 4, \theta \rightarrow \pi, 1 \leq z \leq 3} [\text{IP}_3] = 0.16 \mu\text{M}, \quad (29)$$

$$\lim_{0 \leq r \leq 4, 0 \leq \theta \leq 2\pi, z \rightarrow \{0, 4\}} [\text{IP}_3] = 0.16 \mu\text{M}. \quad (30)$$

## 2.2 Solution

The model eqn (16)–(30) are solved numerically using the Forward Time Centered Space Approach. Using the Forward Time Centered Space Approach, the above eqn (16) and (17) take the following form,

$$\frac{c_{i,j,m}^{n+1} - c_{i,j,m}^n}{k} = \frac{DC}{2} \left\{ \frac{c_{i+1,j,m}^n - 2c_{i,j,m}^n + c_{i-1,j,m}^n}{h^2} + \frac{c_{i+1,j,m}^n - c_{i-1,j,m}^n}{2rh} + \frac{c_{i,j-1,m}^n - 2c_{i,j,m}^n + c_{i,j+1,m}^n}{(rl)^2} + \frac{c_{i,j,m-1}^n - 2c_{i,j,m}^n + c_{i,j,m+1}^n}{(rq)^2} \right\} + \left\{ \frac{V_{IPR} \left( \frac{d_{i,j,m}^n}{d_{i,j,m}^n + K_{IP}} \right)^3 \left( \frac{c_{i,j,m}^n}{c_{i,j,m}^n + K_A} \right)^3 \left( \frac{K_{In}}{K_{In} + c_{i,j,m}^n} \right)^3 (c_E - c_{i,j,m}^n) - V_{SP} \frac{c_{i,j,m}^{n2}}{K_{SP}^2 + c_{i,j,m}^{n2}} + V_{Le} (c_E - c_{i,j,m}^n)}{F_C} \right\}, \quad (31)$$

$$\frac{d_{i,j,m}^{n+1} - d_{i,j,m}^n}{k} = \frac{D_I}{2} \left\{ \frac{d_{i+1,j,m}^n - 2d_{i,j,m}^n + d_{i-1,j,m}^n}{h^2} + \frac{d_{i+1,j,m}^n - d_{i-1,j,m}^n}{2rh} + \frac{d_{i,j-1,m}^n - 2d_{i,j,m}^n + d_{i,j+1,m}^n}{(rl)^2} + \frac{c_{i,j,m-1}^n - 2c_{i,j,m}^n + c_{i,j,m+1}^n}{(rq)^2} \right\} + \left\{ \frac{V_P \left( \frac{c_{i,j,m}^{n2}}{c_{i,j,m}^{n2} + K_P^2} \right) - \lambda \left\{ V_{PP} \left( \frac{d_{i,j,m}^n}{d_{i,j,m}^n + \lambda} \right) + \left( 1 - \frac{c_{i,j,m}^n}{c_{i,j,m}^n + 0.39} \right) V_a \frac{d_{i,j,m}^n}{d_{i,j,m}^n + 2.5} + \frac{c_{i,j,m}^n}{c_{i,j,m}^n + 0.39} V_b \frac{d_{i,j,m}^n}{d_{i,j,m}^n + 0.5} \right\}}{F_C} \right\}, \quad (32)$$

where 'c' denotes the calcium concentration in the cytosol, 'c<sub>E</sub>' denotes calcium concentration in the ER and 'd' denotes the IP<sub>3</sub> concentration, which are a function of (r, θ, z, t). Here, 'h' represents the radial step, 'l' represents the angular step, 'q' represents the height step and 'k' represents the time step. The indexes of the radial, angular and height are 'i', 'j' and 'm' respectively and n represent the index of time. V<sub>a</sub> is the maximum rate constant at low Ca<sup>2+</sup> (3-kinase), V<sub>b</sub> is the maximum rate constant at high Ca<sup>2+</sup> (3-kinase) and V<sub>PP</sub> is the maximum rate constant (phosphatase). The initial and boundary conditions governing the Ca<sup>2+</sup> and IP<sub>3</sub> diffusion processes are given by eqn (18)–(29), which are rewritten as given below.

## (i) Initial condition

At time t = 0 s, we have following initial conditions,

$$c_{i,j,m}^0 = 0.1 \mu\text{M}, \quad (33)$$

$$d_{i,j,m}^0 = 0.16 \mu\text{M}. \quad (34)$$

## (ii) Boundary condition

The above equation is not valid at (r = 0, 0 ≤ θ ≤ 2π, 0 ≤ z ≤ 4), near the sources (r = 4, θ = 0, π, z = 2) and far away from the sources (r = 4, θ = 0, π, 1 ≤ z ≤ 3) and (0 ≤ r ≤ 4, 0 ≤ θ ≤ 2π, z = 0, 4); therefore the approximation at these nodes at t > 0 is given by,

$$\frac{c_{i+1,j,m}^n - c_{i-1,j,m}^n}{2h} = \frac{-\sigma}{2\pi r DC}; \quad \text{at } (r = 4, \theta = \pi, z = 2), \quad (35)$$

$$d_{4,0,2}^n = 0.1882(kn)^6 + 1.3121(kn)^5 + 3.5391(kn)^4 + 4.5312(kn)^3 + 2.5893(kn)^2 + 0.3648(kn) + 0.1691 \leq 3 \quad (36)$$

$$\frac{c_{i+1,j,m}^n - c_{i-1,j,m}^n}{2h} = 0; \quad \text{at } (r = 4, \theta \neq \{0, \pi\}, z = 2), \quad (37)$$

$$\frac{c_{i+1,j,m}^n - c_{i-1,j,m}^n}{2h} = 0; \quad \text{at } (r = 4, \theta \neq 0, z = \{1, 3\}), \quad (38)$$

$$\frac{d_{i+1,j,m}^n - d_{i-1,j,m}^n}{2h} = 0; \quad \text{at } (r = 4, \theta \neq \{0, \pi\}, z = 2), \quad (39)$$

$$\frac{d_{i+1,j,m}^n - d_{i-1,j,m}^n}{2h} = 0; \quad \text{at } (r = 4, \theta \neq \pi, z = \{1, 3\}), \quad (40)$$

$$c_{4,0,m}^n = 0.1 \mu\text{M}; \quad \text{at } (1 \leq z \leq 3), \quad (41)$$

$$c_{i,j,m}^n = 0.1 \mu\text{M}; \quad \text{at } (0 \leq r \leq 4, 0 \leq \theta \leq 2\pi, z = \{0, 4\}), \quad (42)$$

$$d_{4,\pi,m}^n = 0.16 \mu\text{M} \quad \text{at } (1 \leq z \leq 3), \quad (43)$$

$$d_{i,j,m}^n = 0.16 \mu\text{M}; \quad \text{at } (0 \leq r \leq 4, 0 \leq \theta \leq 2\pi, z = \{0, 4\}), \quad (44)$$

The resulting system (31)–(44) provides simultaneous algebraic equations for unknown node concentrations c<sub>i,j,m</sub><sup>n</sup> and d<sub>i,j,m</sub><sup>n</sup>. The Gaussian elimination method has been employed to solve the resulting equations.

## 3 Results and discussion

To start with, we analyzed the cardiomyocyte parameters for biological systems to confirm the accuracy of the computational analysis used in this study. Table 1 presents these properties in a cardiomyocyte. The parameters used for the computation of numerical results are given in Table 1.<sup>48</sup> To facilitate our

**Table 1** The experimental values of different parameters in the cardiac cardiomyocyte

Parameter	Value <sup>48</sup>	Parameter	Value <sup>48</sup>

discussion, all calculations utilize the standard model parameters in Table 1, except where noted otherwise.

Firstly, we discuss the variations of  $IP_3$  and  $Ca^{2+}$  in the cardiomyocyte as a function of angle, radius, height and time (spatio-temporal variation).

### Oscillatory [ $Ca^{2+}$ ] dynamics

The variation of the calcium profile in the cardiomyocyte with respect to time is shown in Fig. 3. Here, the  $Ca^{2+}$  source is assumed to be situated at  $r = 4$ ,  $\theta = \pi$  and  $z = 2$  (i.e.  $50 \text{ } \mu\text{m}$ ). With the increase in time, the calcium concentration near the source also increases and reaches the maximum concentration at  $r = 4 \text{ } \mu\text{m}$ . Also, the maximum calcium concentration was found at  $r = 4$ ,  $\theta = \pi$ ,  $z = 2$  because the source of  $Ca^{2+}$  is located there. Moreover, a small variation occurs but visible away from  $r = 4$  and symmetric variations in both sides around  $\theta = \pi$ . Also, the calcium concentration increases with increasing time and at time  $t = 0$  it satisfied the boundary condition because there is no variation of calcium concentration at the source of calcium.

Initially, the calcium concentration is high at the source because the source channel opens and starts releasing  $Ca^{2+}$ , the calcium concentration in the cytosol increases very fast and then it decreases due to the removal of calcium out of the cell by the pump as we go away from the source. Away from the source,

**Fig. 3**  $Ca^{2+}$  concentration profile in the cardiomyocyte at different points of time ( $t = 0 \text{ s}$  to  $0.03 \text{ s}$  with intervals of  $0.01 \text{ s}$ ) in the cytosol at the  $z = 2$  (i.e.  $50 \text{ } \mu\text{m}$ ) position.

the calcium concentration reaches its steady-state of  $0.1 \text{ } \mu\text{M}$  to maintain the  $Ca^{2+}$  concentration in the cytosol.

### Oscillatory [ $IP_3$ ] dynamics

Now, we discuss the variation of calcium concentration which depends on the spatiotemporal function. Fig. 4 shows the radial and angular distributions of  $Ca^{2+}$  concentration in the cytosol of the cardiomyocyte at different positions  $z$  and  $z$  is varying from 0 to 4 with intervals of 1 in the cell at fixed time  $t = 0.03 \text{ s}$ . It can be observed from the graph that the  $Ca^{2+}$  concentration near the position of the source of  $Ca^{2+}$ , i.e. at  $z = 2$ , is lower than that at  $z = 1$  and  $z = 3$  as the released  $Ca^{2+}$  from the source moves through the cytosol to bind with many proteins like *calmodulin* to activate various cellular responses like contraction, metabolism etc. Also, we can see that the calcium concentrations are very small at the end of the cytosol of the cardiomyocyte ( $z = 0$  and  $z = 4$ ) because it is away from the calcium source. Moreover,  $z = 2$  means at the calcium source, and the  $Ca^{2+}$  concentration is high near the source, and away from the source, its concentration decreases very slowly as shown in Fig. 4 at  $z = 2$ . According to this, calcium signaling shows a wave-like nature at the source of calcium. Also, away from the source, i.e. at  $z = 0$  and  $z = 4$ ,  $IP_3$  concentration again decreases gradually to attain its background concentration  $0.1 \text{ } \mu\text{M}$ .

Furthermore, we have systematically investigated the effect of the  $IP_3$  source on each parameter of the spatiotemporal function and its variation is shown in Fig. 5. Fig. 5 shows the changes in  $IP_3$  concentration at different time intervals. Here, the  $IP_3$  source is assumed to be situated at  $r = 4$ ,  $\theta = 0$  and  $z = 2$  (i.e.  $50 \text{ } \mu\text{m}$ ). With the increase in time, the  $IP_3$  concentration near the source also increases. As the time increases, the concentration of  $IP_3$  increases and shows an oscillatory type of

**Fig. 4**  $Ca^{2+}$  concentration profile in the cardiomyocyte at different positions  $z$  in the cytosol at  $t = 0.03 \text{ s}$ .

Fig. 5  $IP_3$  concentration profile in the cardiomyocyte at different points of time in the cytosol at the  $z = 2$  (i.e.  $50 \mu\text{m}$ ) position.

behaviour in the radial as well as the angular directions. Also, the maximum variation is seen at time  $t = 0.03 \text{ s}$  at the source of  $IP_3$  and oscillations start from  $\theta = \pi$  where maximum values are reached either side of the source ( $\theta = 0, 2\pi$ ). Initially, the  $IP_3$  concentration decreases as we go away from the source then it increases to match the boundary concentration i.e.  $3 \mu\text{M}$ .

Moreover, the variation of  $IP_3$  concentration which is the function of the radial as well as the angular part also depends on the height of the cylindrical cardiomyocyte. Fig. 6 shows the radial and angular distributions of the  $IP_3$  concentration in the cytosol of the cardiomyocyte at different positions  $z$  in the cell at  $t = 0.03 \text{ s}$ . It can be observed from the graph that the  $IP_3$  concentration near the position of the source of  $IP_3$ , i.e. at  $z = 2$ , is lower than that at  $z = 1$  and  $z = 3$  as the released  $IP_3$  from the

Fig. 6  $IP_3$  concentration profile in the cardiomyocyte at different positions  $z$  in the cytosol at  $t = 0.03 \text{ s}$ .

source moves through the cytosol to bind with the calcium release channel  $IP_3R$  in order to allow the channel to open so that free  $Ca^{2+}$  ions can be released from the endoplasmic reticulum to balance the  $Ca^{2+}$  concentration in the cytosol and also to allow various cellular responses. Also, away from the source, i.e. at  $z = 0$  and  $z = 4$ , the  $IP_3$  concentration again decreases gradually to attain its background concentration of  $0.16 \mu\text{M}$ .

### Influence of $[IP_3]$ in the $[Ca^{2+}]$ dynamics

Now, we discuss the ratio of  $Ca^{2+}$  and  $IP_3$  concentrations as a function of time at fixed height  $z = 2$  and different radial and angular positions as shown in Fig. 7. As time increases at a different position in the cytosol, the ratio of  $c = [Ca^{2+}]$  and  $d = [IP_3]$  decreases very fast, after that it starts increasing and after a small decrease, it increases again and attains a steady-state. The maximum variation is seen at  $(r = 4, \theta = 0, z = 2)$  which is the location of the source of  $IP_3$ . Physiologically this behaviour of interdependent  $Ca^{2+}$  and  $IP_3$  is justified. At the center of the cytosol, i.e. at  $z = 2$ , maximum interdependent dynamics and non-linearity in these signaling patterns are observed which is shown in Fig. 7. This is due to the positioning of the two source channels of  $Ca^{2+}$  and  $IP_3$ . The source of  $Ca^{2+}$  is located at  $(r = 4, \theta = \pi, z = 2)$  and the source of  $IP_3$  is located at  $(r = 4, \theta = 0, z = 2)$  which are just opposite to each other. Initially,  $d = [IP_3]$  is higher as compared to  $c = [Ca^{2+}]_C$  due to the initial conditions of both the signals. At time  $t = 0 \text{ s}$ , initial conditions are  $c_{i,j,m}^0 = 0.1 \mu\text{M}$  and  $d_{i,j,m}^0 = 0.16 \mu\text{M}$ . Also, the equation for the source of  $IP_3$  increases rapidly with time as compared to the source of  $Ca^{2+}$ . Therefore, a rapid decrease in the ratio of  $c = [Ca^{2+}]_C$  and  $d = [IP_3]$  is seen in the first few milliseconds. But after that, it is observed that there is a sharp peak in the ratio  $c/d$ , after this point of time the ratio  $c/d$  starts increasing. At this point of time, the  $IP_3$  binds with the  $IP_3$

Fig. 7 Ratio of  $c = [Ca^{2+}]_C$  and  $d = [IP_3]$  with respect to time in the cytosol of the cardiomyocyte at different positions ( $r = 4 \mu\text{m}, \theta = \pi, z = 2$ ), ( $r = 2 \mu\text{m}, \theta = \pi, z = 2$ ), ( $r = 0 \mu\text{m}, \theta = 0, z = 2$ ), ( $r = 2 \mu\text{m}, \theta = 0, z = 2$ ) and ( $r = 4 \mu\text{m}, \theta = 0, z = 2$ ).

receptor (IP<sub>3</sub>R), opens the IP<sub>3</sub>R channel and facilitates the outflow of Ca<sup>2+</sup> ions from the ER to the cytosol. As a result, the amount of Ca<sup>2+</sup> ions increases in the cytosol. Therefore, the ratio  $c/d$  increases. This increase in the cytosolic Ca<sup>2+</sup> concentration will help in finding treatment for cancer.<sup>4</sup> These released free Ca<sup>2+</sup> ions from the ER are not all breaking PIP<sub>2</sub> to form IP<sub>3</sub> ions, there are many proteins available in the cytosol which bind with the released free Ca<sup>2+</sup> ion to stimulate various cell responses. Also, the SERCA pump is present which pumps out the extra free Ca<sup>2+</sup> ions from the cytosol to the ER to maintain a balanced amount of free Ca<sup>2+</sup> ions inside the cytosol. This binding of free Ca<sup>2+</sup> ions with proteins and pumping out process lead to a decrease in the amount of free cytosolic Ca<sup>2+</sup> ions as compared to the cytosolic IP<sub>3</sub>. This is the reason behind the decrease in ratio  $c/d$ . Near 0.6 s again the ratio  $c/d$  increases and attains an equilibrium state. Physiologically, when the amount of free Ca<sup>2+</sup> ions in the cytosol decreases then the leak (Le) located at the ER membrane starts releasing a small amount of Ca<sup>2+</sup> ions into the cytosol to maintain the balance and initiate the whole process of intracellular cell signaling cell signaling. It is observed that after 0.6 s, at all the positions equilibrium between  $c = [Ca^{2+}]_C$  and  $d = [IP_3]$  is attained.

### Effect of leak on Ca<sup>2+</sup> dynamics

Fig. 8 shows the behaviour of the ratio of concentrations as a function of time, and we have as well included the effects of leak. The main function of leak helps to facilitate the flow of

Fig. 8 The effect of leak (Le) on the ratio of  $c = [Ca^{2+}]_C$  and  $d = [IP_3]$  with respect to time at various positions *i.e.*, radius ( $r$ ) and angle ( $\theta$ ) in the cardiomyocyte. (a)  $r = 4 \mu\text{m}$ ,  $\theta = \pi$ ,  $z = 2$ , (b)  $r = 2 \mu\text{m}$ ,  $\theta = \pi$ ,  $z = 2$ , (c)  $r = 0 \mu\text{m}$ ,  $\theta = 0$ ,  $z = 2$ , (d)  $r = 2 \mu\text{m}$ ,  $\theta = 0$ ,  $z = 2$  and (e)  $r = 4 \mu\text{m}$ ,  $\theta = 0$ ,  $z = 2$  in the cytosol of the cardiomyocyte.

Ca<sup>2+</sup> ions in the cytosol from the ER which increases the Ca<sup>2+</sup> concentration in the cytosol and initiates the complete Ca<sup>2+</sup> dynamic processes. The ratio concentration of Ca<sup>2+</sup> and IP<sub>3</sub> initially decreases with time and then immediately the ratio concentration starts increasing at a certain time, showing an oscillatory pattern and then it goes to a steady-state with the presence of leak. In the case of absent leak, the behaviour is the same but there is a decrease in ratio concentration which is shown in Fig. 8(a)–(e).

Also, we have simulated the other compositions of the radial and angular parts of a cardiomyocyte inside the cytosol which is the function of ratio concentration and time. We found that the behaviour is similar to Fig. 8(a)–(e) but at  $z = 2$  the graph shows a better oscillatory type nature due to the positioning of both the sources is at  $z = 2$ . This shows that the cytosolic Ca<sup>2+</sup> concentration can be increased by increasing the effect of leak in the cardiomyocyte.

### Effect of $\sigma$ on Ca<sup>2+</sup> dynamics

Fig. 9 shows the behaviour of the ratio concentration as a function of time at different amounts of the Ca<sup>2+</sup> source influx. The same behaviour is found as in Fig. 8 but if we increase the amount of Ca<sup>2+</sup> source influx, the ratio concentrations of Ca<sup>2+</sup> and IP<sub>3</sub> continuously increase. But in the case of  $r = 4 \mu\text{m}$  and  $\theta = 0$ , there is no change in the ratio as at this position which is far away from the source of calcium it is assumed in the boundary condition that  $c = [Ca^{2+}]_C$  is fixed *i.e.* 0.1  $\mu\text{M}$ .

Fig. 9 The effect of the source influx of Ca<sup>2+</sup> ( $\sigma$ ) on the ratio of  $c = [Ca^{2+}]_C$  and  $d = [IP_3]$  with respect to time at various positions *i.e.*, radius ( $r$ ) and angle ( $\theta$ ) in the cardiomyocyte. (a)  $\theta = \pi$  and  $r = 4 \mu\text{m}$ , (b)  $\theta = \pi$  and  $r = 2 \mu\text{m}$ , (c)  $\theta = 0$  and  $r = 0 \mu\text{m}$ , (d)  $\theta = 0$  and  $r = 2 \mu\text{m}$ , (e)  $\theta = 0$  and  $r = 4 \mu\text{m}$  in the cytosol of the cardiomyocyte.

Therefore, the effect of an increase in  $\text{Ca}^{2+}$  source influx ( $\sigma$ ) is negligible here. This analysis also suggests that the cytosolic  $\text{Ca}^{2+}$  concentration can be increased by increasing the source influx of calcium ( $\sigma$ ) in the cardiomyocyte which will help in finding various treatments for cancer.

### Effect of $V_P$ on $\text{Ca}^{2+}$ dynamics

Lastly, we have simulated the ratio concentration with respect to time at various values of the maximum rate of production of  $\text{IP}_3$  as depicted in Fig. 10. Here, we can see that the variation in ratio concentration initially decreases and then it increases very rapidly showing an oscillatory behaviour after that it goes to a steady-state. But in the case of  $r = 4 \mu\text{m}$  and  $\theta = 0$ , the ratio concentration is the same at different  $V_P$  because it is a boundary point which is away from the source so it is not affected by the maximum rate production of  $\text{IP}_3$ . From Fig. 9 and 10 we can easily see that the  $\text{Ca}^{2+}$  and  $\text{IP}_3$  concentrations affect each other non-linearly. But Fig. 9 and 10 suggest that the maximum rate of production of  $\text{IP}_3$  ( $V_P$ ) can affect more as compared to the  $\text{Ca}^{2+}$  source influx ( $\sigma$ ) because if we are increasing the maximum rate of production of  $\text{IP}_3$ , the ratio peaks are shifted towards higher values. This means that the  $\text{Ca}^{2+}$  concentration in the cytosol is much more affected by  $\text{IP}_3$  parameters which indicates that experimental researchers can explore various ways to kill the cancerous cell by increasing the cytosolic calcium concentration with the help of controlling  $\text{IP}_3$  dynamics in cardiomyocytes as  $\text{IP}_3$  signaling plays a very

important role in regulation of the calcium concentration in cardiomyocytes.

### $[\text{Ca}^{2+}]$ dynamics in cancer therapy

Dynamics of free intracellular calcium concentration ( $[\text{Ca}^{2+}]$ ) are a crucial control mechanism in many cell types.<sup>53</sup> The temporal and spatial information encoded by these dynamic signals controls many processes, including contraction of the cardiac tissues, information processing in the brain, gene expression, release of digestive enzymes by the liver, differentiation and cell movement.<sup>54</sup> Imbalanced calcium signaling has been associated with major pathologies, such as cardiovascular disease, stroke and cancer.<sup>55,56</sup> The results found here are in good agreement with the experimental as well as theoretical work<sup>26,28,43,57</sup> and suggest new insights into finding treatment for cancer in cardiomyocytes through elevation of the cytosolic  $\text{Ca}^{2+}$  concentration by various parameters like *leak*,  $\sigma$ ,  $V_P$  and especially by other complex cell signaling dynamics, namely the  $\text{IP}_3$  dynamics.

## 4 Conclusion

As suggested by Chaochu Cui *et al.*,<sup>58</sup> alterations in intracellular  $\text{Ca}^{2+}$  signaling for cancer therapy has become an emerging research area. Thus, keeping in mind this ideology, the physiological processes like reaction–diffusion of calcium and  $\text{IP}_3$  are taken into consideration. One of the mechanisms of the killing of the cancerous cell by nanoparticles is through elevation of the intracellular calcium level. Our study suggests that there are other factors involved in this signaling which can increase the calcium level, which can help in finding a cure for cancer. Thus, a possible treatment for cancer may be studied and the preventive step of increasing the calcium concentration can be studied mathematically. In this piece of research, the effect of  $\text{IP}_3$  dynamics in the presence of *leak*, source influx of calcium ( $\sigma$ ) and maximum production of  $\text{IP}_3$  ( $V_P$ ) on the cytosolic calcium dynamics is presented. Several graphs depicting the physiological phenomenon of calcium and  $\text{IP}_3$  dynamics are plotted here to give a better insight into the interdependence of these signaling processes. In all the ratio graphs (see Fig. 7–10), the nonlinear relationship between these two signaling processes is visible. Here, *leak*, source influx of calcium ( $\sigma$ ) and maximum production of  $\text{IP}_3$  ( $V_P$ ) are taken into consideration and are found to play important roles in increasing the amount of cytosolic calcium concentration with the help of  $\text{IP}_3$  signaling that would be helpful in finding treatment for cancer. Hence, the impact of  $\text{IP}_3$  signaling in calcium diffusion is found to be significant. The cytosolic calcium level may be controlled by  $\text{IP}_3$  signaling, *leak*, source influx of calcium ( $\sigma$ ) and maximum production of  $\text{IP}_3$  ( $V_P$ ). The present work focuses on the evaluation of the various parameters that affect these coupled dynamics and elevate the cytosolic calcium concentration which can be helpful to search for novel therapies to treat these malignancies by targeting complex calcium signaling processes in cardiomyocytes.

Fig. 10 The effect of the maximum  $\text{IP}_3$  production rate ( $V_P$ ) on the ratio of  $c = [\text{Ca}^{2+}]_C$  and  $d = [\text{IP}_3]$  with respect to time at various positions *i.e.*, radius ( $r$ ) and angle ( $\theta$ ) in the cardiomyocyte. (a)  $\theta = \pi$  and  $r = 4 \mu\text{m}$ , (b)  $\theta = \pi$  and  $r = 2 \mu\text{m}$ , (c)  $\theta = 0$  and  $r = 0 \mu\text{m}$ , (d)  $\theta = 0$  and  $r = 2 \mu\text{m}$ , (e)  $\theta = 0$  and  $r = 4 \mu\text{m}$  in the cytosol of the cardiomyocyte.
