# Thermal and structural properties, and molecular dynamics in organic–inorganic hybrid perovskite $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$

Ae Ran Lim \*<sup>ab</sup>

The thermal and structural properties and molecular dynamics of layered perovskite-type  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  are investigated by differential scanning calorimetry, thermogravimetric analysis, and magic angle spinning nuclear magnetic resonance spectroscopy. The thermal properties and phase transitions are studied. Additionally, the Bloembergen–Purcell–Pound (BPP) curves for the  $^1\text{H}$  spin–lattice relaxation time  $T_{1\rho}$  in the  $\text{C}_2\text{H}_5\text{NH}_3$  cation and for the  $^{13}\text{C}$   $T_{1\rho}$  in  $\text{C}_2\text{H}_5$  are shown to have minima as a function of inverse temperature. This observation implies that these curves represent the rotational motions of  $^1\text{H}$  and  $^{13}\text{C}$  in the  $\text{C}_2\text{H}_5\text{NH}_3$  cation. The activation energies for  $^1\text{H}$  and  $^{13}\text{C}$  in the  $\text{C}_2\text{H}_5\text{NH}_3$  cation are obtained; the molecular motion of  $^1\text{H}$  is enhanced at the C-end and N-end of the organic cation, and that at the carbons of the main chain is not as free as that for protons at the C-end and N-end.

## 1. Introduction

Hybrid organic–inorganic compounds allow for the possibility of combining the properties of organic and inorganic materials at the molecular level.<sup>1–4</sup> This class of hybrid materials is very broad and offers a wide set of different structures, properties, and potential applications.<sup>5–12</sup> A new type of layered perovskite multiferroic,  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{CuCl}_4$ , as a metal organic compound was found by Kundys *et al.*<sup>6</sup> Multiferroics refer to materials that simultaneously have two or more of the following properties: spontaneous ferroelectricity, ferromagnetism, or ferroelasticity.<sup>13</sup>  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{CuCl}_4$  crystallizes in a layered perovskite structure consisting of nearly isolated layers of corner-sharing  $\text{ZnCl}_6$  octahedra, and the interlayer distance is approximately 10 Å, where the layers are separated by two layers of ethylammonium cations  $(\text{C}_2\text{H}_5\text{NH}_3)^+$ .<sup>14</sup> The  $\text{NH}_3$  polar heads of the chains are linked to the chlorine ions of the  $\text{ZnCl}_6$  octahedra by three hydrogen bonds  $\text{N}\cdots\text{H}\cdots\text{Cl}$ . The organic chains are joined by weak hydrogen bonds from the  $\text{NH}_3$  groups to the Cl ions. One interesting series is the metal–organic hybrids of chemical formula such as  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  with perovskite-type transition metal salts. A study of the electrical, dielectric, and optical properties of  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  was reported by Mohamed *et al.*<sup>15</sup> They found that  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  is a layered perovskite-type compound that undergoes five phase transitions at 231 K, 234 K, 237 K, 247 K, and 312 K as determined by differential scanning calorimetry (DSC).<sup>15</sup> The intensities of the endotherm peaks at 231 K, 237 K, and 312 K are very weak and perhaps

correspond to second-order transformations. Tello<sup>16</sup> reported a ferroelastoelectric phase transition at 243.3 K by optical and X-ray measurements with a group theoretical analysis. The phase transitions in this crystal are mostly connected to changes in the arrangement of the alkylammonium chains. The crystal structure of  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  at room temperature is orthorhombic. Fig. 1 reveals that its atomic arrangement can be described by an alternation of the organic and inorganic entities in the *bc* plane. This compound is characterized by two

Fig. 1 Orthorhombic structure of a  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  crystal for *bc*-plane at room temperature.<sup>18</sup>

<sup>a</sup>Analytical Laboratory of Advanced Ferroelectric Crystals, Jeonju University, Jeonju 55069, South Korea. E-mail: aeranlim@hanmail.net; arlim@jju.ac.kr

<sup>b</sup>Department of Science Education, Jeonju University, Jeonju 55069, South Korea

simple hydrogen bonds  $\text{N-H}\cdots\text{Cl}$  linking the organic  $(\text{C}_2\text{H}_5\text{NH}_3)^+$  cation to the  $(\text{ZnCl}_4)^{2-}$  tetrahedral anions.<sup>17</sup> This compound is crystallized in the orthorhombic system with a space group of  $Pna2_1$  at room temperature, and the lattice parameters are  $a = 10.043 \text{ \AA}$ ,  $b = 17.594 \text{ \AA}$ ,  $c = 7.397 \text{ \AA}$ , and molecules per unit cell,  $Z = 4$ .<sup>18</sup> The Zn atoms in  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  are tetrahedrally coordinated, while the Cu atoms in  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{CuCl}_4$  are octahedrally coordinated. Although the chemical composition of the Zn and Cu compounds is similar, the coordination of the metal atom is different.

The structural geometry and molecular dynamics of the organic molecules within the layered hybrid structure are important for determining the influence of temperature on the evolution of structural phase transitions in the perovskite structure. Physical properties in particular depend on the characteristics of the metallic anion and the organic cation. Until now, the physical properties of  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  have been reported by a few research groups, whereas the thermal properties and molecular dynamics have not been studied.

The goal of this work is to analyze the crystal growth, thermodynamic properties, and structural dynamics of a  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  single crystal. The analysis is based on DSC, thermogravimetric analysis (TGA), and magic angle spinning nuclear magnetic resonance (MAS NMR). We measured the line widths, chemical shifts, and spin–lattice relaxation times ( $T_{1\rho}$ ) in the rotating frame using  $^1\text{H}$  MAS NMR,  $^{13}\text{C}$  cross-polarization (CP)/MAS NMR, and  $^{14}\text{N}$  static NMR as a function of temperature. The molecular dynamics of the  $(\text{C}_2\text{H}_5\text{NH}_3)$  cation were investigated near the phase transition temperatures, and we discussed the activation energies for the molecular dynamics of  $\text{C}_2\text{H}_5$  and  $\text{NH}_3$  in the  $(\text{C}_2\text{H}_5\text{NH}_3)^+$  cation. Furthermore, we have compared the molecular motions of  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  obtained here and those of the previously reported  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{CuCl}_4$ .

## II. Experimental methods

Crystals of  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  were prepared by dissolving stoichiometric amounts of the starting materials, commercial  $\text{CH}_3\text{CH}_2\text{NH}_2 \cdot \text{HCl}$  (ethylamine hydrochloride, Aldrich 98%) and  $\text{ZnCl}_2$ , in water. Single crystals were grown by a slow evaporation of the aqueous solution at room temperature. The obtained crystals were colorless and hexagonal in shape.

The thermal stability was checked by means of TGA and optical polarizing microscopy. The TGA curve at a heating rate of  $10 \text{ }^\circ\text{C min}^{-1}$  was measured under  $\text{N}_2$  atmosphere, and the mass of the powdered sample used in the TGA experiment was 6.63 mg. The phase transitions were performed by DSC in the temperature range of 300–670 K with  $10 \text{ }^\circ\text{C min}^{-1}$  heating rates.

The line widths, chemical shifts, and  $T_{1\rho}$  values for  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  were obtained by  $^1\text{H}$  MAS NMR and  $^{13}\text{C}$  CP/MAS NMR at Larmor frequencies of  $\omega_0/2\pi = 400.13$  and  $100.62$  MHz, respectively, using a Bruker 400 MHz NMR spectrometer at the Korea Basic Science Institute, Western Seoul Center. Powdered samples were placed within a 4 mm CP/MAS probe, and the MAS rate for  $^1\text{H}$  and  $^{13}\text{C}$  measurements, to minimize spinning sideband overlap, was set to 10 kHz. The  $^1\text{H}$   $T_{1\rho}$  values were determined using a  $\pi/2 - t$  sequence by varying the

duration of spin-locking pulses.  $^{13}\text{C}$   $T_{1\rho}$  values were measured by varying the duration of the spin-locking pulse applied after the CP preparation period. The width of the  $\pi/2$  pulse used for measuring  $T_{1\rho}$  for  $^1\text{H}$  and  $^{13}\text{C}$  was  $3.7 \text{ }\mu\text{s}$ , with the spin-locking field set at 67.56 kHz. The chemical shifts and  $T_{1\rho}$  were measured over a temperature range of 180–430 K.

In addition, the  $^{14}\text{N}$  NMR spectra of the  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  single crystals in the laboratory frame were measured using a Unity INOVA 600 NMR spectrometer at the same facility. The static magnetic field was 14.1 T and the Larmor frequency was set to  $\omega_0/2\pi = 43.345$  MHz. The  $^{14}\text{N}$  NMR experiments were conducted using a solid-echo ( $\pi/2 - t - \pi/2 - t$ ) pulse sequence. The width of the  $\pi/2$  pulse was  $4 \text{ }\mu\text{s}$ .

## III. Experimental results

Fig. 2 shows the simultaneous TGA and DSC curves for the  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  single crystal. A drastic weight loss onset occurred at 460 K ( $=T_d$ ), which is attributed to the beginning of the evaporation of  $\text{C}_2\text{H}_5\text{NH}_2$  and  $\text{HCl}$  due to partial thermal decomposition. The sample lost weight sharply between 500 K and 670 K, with a corresponding weight loss of 48%, which agrees almost exactly with the content of the organic component (45.53%) of  $\text{C}_2\text{H}_5\text{NH}_3\text{Cl}$  in  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$ . DSC studies on the perovskite were undertaken to demonstrate structural transitions below the melting/decomposition point. In the DSC curve, the endotherm peaks at 320 K, 376 K, and 438 K correspond to the phase transitions. The  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  undergoes phase transitions at 438 K, 376 K, and 320 K, which are denoted as the  $T_{C1}$ ,  $T_{C2}$ , and  $T_{C3}$  with decreasing temperature. As the temperature increases, the crystal is constantly colorless and transparent (300 K, 400 K, 450 K), and then it starts melting near 460 K. The crystal is melted near 475 K, as shown in the inset in Fig. 2.

The  $^1\text{H}$  NMR spectra at a frequency of 400.13 MHz were obtained by MAS NMR. The  $^1\text{H}$  spectrum recorded at 300 K is

Fig. 2 TGA and DSC curves of  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  crystal (inset: changes of a  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  crystal according to the temperature: (a) 300 K, (b) 400 K, (c) 450 K, (d) 460 K, (e) 470 K, and (f) 475 K).

shown in the inset in Fig. 3. The observed resonance line has an asymmetric shape, as the full-width at half-maximum (FWHM) values on the left side (symbol 1) and right side (symbol 2) are not the same. The asymmetric line shape is attributed to the two overlapping lines for  $C_2H_5$  and  $NH_3$ . Additionally, the FWHM line width narrows significantly with increasing temperature, as shown in Fig. 3. Note that there is no abrupt change in the line width near  $T_{C3}$  and  $T_{C4}$ , whereas near  $T_{C2}$  it is abruptly decreased. Here, the  $T_{C4}$  ( $=247$  K) is the previously reported phase transition temperature.<sup>16</sup>

The asymmetric line shape in the inset in Fig. 3 is attributed to the  $C_2H_5$  and  $NH_3$  overlapping lines. Thus, the overlapping peak is very broad. However, the spinning sidebands of the two types are evident in Fig. 3. Therefore, the peaks for  $C_2H_5$  and  $NH_3$  by distance of sidebands can be distinguished. The spinning sidebands for  $C_2H_5$  were marked with asterisks, while those for  $NH_3$  were marked with crosses. The peak of the lower chemical shift was attributed to  $^1H$  in  $C_2H_5$ , while that of the higher chemical shift was attributed to  $^1H$  in  $NH_3$ . The spectrum at 300 K consisted of two peaks at chemical shifts of  $\delta = 3.05$  ppm and  $\delta = 7$  ppm, which were assigned to the  $^1H$  in the ethyl group  $C_2H_5$  and the ammonium group  $NH_3$ , respectively. The  $^1H$  chemical shifts for methyl and ammonium groups were nearly constant with temperature, as shown in Fig. 4.

In order to obtain the  $^1H$  relaxation time values, the magnetization recovery curves as a function of delay time were measured at several temperatures for  $(C_2H_5NH_3)_2ZnCl_4$ . The magnetization recovery curves for various delay times for  $^1H$  at 300 K are shown in Fig. 5. All traces obtained can be described by the single-exponential function<sup>19,20</sup>

$$P(t)/P_0 = \exp(-t/T_{1\rho}), \quad (1)$$

where  $P(t)$  is the magnetization as a function of the spin-locking pulse duration  $t$ , and  $P_0$  is the total nuclear magnetization of the

Fig. 3 Line widths for  $^1H$  MAS NMR spectrum of  $(C_2H_5NH_3)_2ZnCl_4$  as a function of temperature (inset:  $^1H$  MAS NMR spectrum of  $(C_2H_5NH_3)_2ZnCl_4$  represented spinning sidebands indicated by asterisks and crosses at 300 K).

Fig. 4 Chemical shifts for  $^1H$  MAS NMR of  $(C_2H_5NH_3)_2ZnCl_4$  as a function of temperature.

proton at thermal equilibrium. The recovery traces are shown for delay times ranging from 0.2 ms to 70 ms. The  $T_{1\rho}$  values were obtained from the slopes of the delay time vs. intensity. This analysis method was used to obtain the  $T_{1\rho}$  values for the protons, which are plotted as a function of inverse temperature in Fig. 6. From these results, the spin-lattice relaxation time in the rotating frame was obtained, and its temperature dependences are shown in Fig. 6.

The  $T_{1\rho}$  values of protons in the  $(C_2H_5NH_3)_2ZnCl_4$  are almost continuous near  $T_{C3}$  and  $T_{C4}$ , and these values are on the order of a few milliseconds. The  $T_{1\rho}$  values abruptly decreased with temperature in the region approaching  $T_{C2}$ . The relaxation time for the  $^1H$  nucleus has minimum values of 2.17 ms and 2.48 ms at 260 K and 330 K, respectively. This feature of  $T_{1\rho}$  indicates distinct molecular motions. The  $T_{1\rho}$  values are related to the corresponding values of the rotational correlation time,  $\tau_C$ ,

Fig. 5 The  $^1H$  recovery traces as a function of the delay time at 300 K.

Fig. 6  $^1\text{H}$  spin-lattice relaxation times  $T_{1\rho}$  in the rotating frame and correlation time of  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  as a function of inverse temperature.

which is a direct measure of the rate of molecular motion. For the spin-lattice relaxation time in the rotating frame, the experimental value of  $T_{1\rho}$  can be expressed in terms of the correlation time  $\tau_c$  for the molecular motion as suggested by the Bloembergen-Purcell-Pound (BPP) theory:<sup>21,22</sup>

$$T_{1\rho}^{-1} = (N/20)(\gamma_{\text{H}} \gamma_{\text{C}} \hbar / r_{\text{H-C}})^2 \{4f(\omega_1) + f(\omega_{\text{H}} - \omega_{\text{C}}) + 3f(\omega_{\text{C}}) + 6f(\omega_{\text{H}} + \omega_{\text{C}}) + 6f(\omega_{\text{H}})\};$$

$$f(\omega_1) = \tau_c / (1 + \omega_1^2 \tau_c^2), f(\omega_{\text{H}} - \omega_{\text{C}}) = \tau_c / [1 + (\omega_{\text{H}} - \omega_{\text{C}})^2 \tau_c^2],$$

$$f(\omega_{\text{C}}) = \tau_c / (1 + \omega_{\text{C}}^2 \tau_c^2), f(\omega_{\text{H}} + \omega_{\text{C}}) = \tau_c / [1 + (\omega_{\text{H}} + \omega_{\text{C}})^2 \tau_c^2],$$

$$f(\omega_{\text{H}}) = \tau_c / (1 + \omega_{\text{H}}^2 \tau_c^2). \quad (2)$$

Here,  $\gamma_{\text{H}}$  and  $\gamma_{\text{C}}$  are the gyromagnetic ratios for the  $^1\text{H}$  and  $^{13}\text{C}$  nuclei, respectively;  $N$  is the number of directly bound protons;  $r_{\text{H-C}}$  is the H-C internuclear distance;  $\hbar$  is the reduced Planck constant;  $\omega_{\text{H}}$  and  $\omega_{\text{C}}$  are the Larmor frequencies of  $^1\text{H}$  and  $^{13}\text{C}$ , respectively; and  $\omega_1$  is the frequency of the spin-locking field of 67.56 kHz. We analyzed our data assuming that  $T_{1\rho}$  would show a minimum when  $\omega_1 \tau_c = 1$ , and that the BPP relation between  $T_{1\rho}$  and the characteristic frequency  $\omega_1$  could be applied. We sensitively controlled the minima in the  $T_{1\rho}$  temperature variations and the slopes around the minima. From these results, the value of  $(\gamma_{\text{H}} \gamma_{\text{C}} \hbar / r_{\text{H-C}})^2$  for the constant in eqn (2) was obtained. We then calculated the temperature dependences of the  $\tau_c$  values for protons by using the obtained values of  $(\gamma_{\text{H}} \gamma_{\text{C}} \hbar / r_{\text{H-C}})^2$ . The temperature dependence of  $\tau_c$  follows a simple Arrhenius equation:<sup>21</sup>

$$\tau_c = \tau_0 \exp(-E_a/RT), \quad (3)$$

where  $\tau_0$  is a pre-exponential factor,  $T$  is the temperature,  $R$  is the gas constant, and  $E_a$  is the activation energy. Thus, the slope of the linear portion of a semi-log plot should yield  $E_a$ . The  $E_a$  value for the rotational motion can be obtained from the log  $\tau_c$  vs.  $1000/T$  curve shown in Fig. 6; we obtained  $E_a = 39.41 \pm 1.56 \text{ kJ mol}^{-1}$  and  $E_a = 57.59 \pm 2.96 \text{ kJ mol}^{-1}$  for high and low temperatures, respectively. Here,  $T_{1\rho}$  and  $E_a$  for  $^1\text{H}$  are averaged

for all hydrogens in the  $(\text{C}_2\text{H}_5\text{NH}_3)$  cation. The rotational motion for protons at the end of the organic cation is more activated at the low temperature than at the high temperature.

Structural analysis of the  $^{13}\text{C}$  in  $\text{C}_2\text{H}_5$  was also performed using  $^{13}\text{C}$  CP/MAS NMR. The  $^{13}\text{C}$  MAS NMR spectrum for  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  is shown in Fig. 7 as a function of temperature. The overlapped two signals in the spectrum for  $\text{CH}_3$  and  $\text{CH}_2$  in  $\text{C}_2\text{H}_5$  are shown in Fig. 7. The resonance line has an asymmetric shape, similar to the  $^1\text{H}$  line shape. At 200 K, the chemical shifts of  $\delta = 36.51 \text{ ppm}$  and  $\delta = 37.12 \text{ ppm}$  with respect to tetramethylsilane (TMS) are assigned to  $\text{CH}_3$  and  $\text{CH}_2$ , respectively. The chemical shifts above 250 K were only continuous changes, whereas there was an abrupt change near 250 K. The change in the chemical shift is associated with a structural phase transition occurring at this temperature.

The nuclear magnetization was also measured as a function of delay time in order to obtain the  $^{13}\text{C}$   $T_{1\rho}$  values. The signal intensity of the nuclear magnetization recovery curves for  $^{13}\text{C}$  is described by a single exponential function of eqn (1) at all temperatures. The  $^{13}\text{C}$   $T_{1\rho}$  values for  $\text{C}_2\text{H}_5$  in  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  are plotted as a function of inverse temperature in Fig. 8. The  $^{13}\text{C}$   $T_{1\rho}$  values near the phase-transition temperatures  $T_{\text{C}3}$  and  $T_{\text{C}4}$  are approximately continuous, whereas the  $T_{1\rho}$  near  $T_{\text{C}2}$  is abruptly decreased, similar to the  $^1\text{H}$   $T_{1\rho}$ . The  $T_{1\rho}$  value for carbon at room temperature is 13.65 ms. The  $T_{1\rho}$  curve below  $T_{\text{C}2}$  can be reproduced by BPP theory, and the BPP curve shows a minimum of 6.30 ms at 260 K. The correlation time for the rotational motion of  $\text{C}_2\text{H}_5$  is obtained, and the activation energy from the log  $\tau_c$  vs.  $1000/T$  curve shown in Fig. 8; we obtained  $E_a = 21.13 \pm 1.27 \text{ kJ mol}^{-1}$ .

In order to obtain information concerning the phase transition near 247 K ( $=T_{\text{C}4}$ ), the NMR spectrum of  $^{14}\text{N}$  ( $I = 1$ ) in the laboratory frame was obtained. Two resonance signals with respect to  $\text{NH}_4\text{Cl}$  were expected from the quadrupole interactions of the  $^{14}\text{N}$  nucleus. The  $^{14}\text{N}$  NMR spectra in  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  single crystals between 220 K and 290 K are plotted in

Fig. 7  $^{13}\text{C}$  CP/MAS NMR spectra of  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  measured at different several temperatures.

Fig. 8  $^{13}\text{C}$  spin-lattice relaxation times  $T_{1\rho}$  in the rotating frame and correlation time of  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  as a function of inverse temperature.

Fig. 9 The resonance frequency of  $^{14}\text{N}$  NMR spectra in  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  single crystal between 220 K and 290 K.

Fig. 9. The number of resonance lines varies near 243 K; the  $^{14}\text{N}$  signals below 240 K show two resonance lines denoted by symbol 1, whereas those above 240 K show four resonance lines denoted by symbols 1 and 2. These four signals are attributed to the N(1) and N(2) sites in the physically inequivalent  $\text{NH}_3$  (1) and  $\text{NH}_3$  (2) ions, respectively. The abrupt splitting of the  $^{14}\text{N}$  NMR line is related to the phase transition at 247 K. This splitting of the  $^{14}\text{N}$  resonance signals is nearly constant with temperature. However, the  $^{14}\text{N}$  NMR spectrum above 300 K could not be detected due to a low intensity.

## IV. Conclusion

We discussed the molecular motions of cations of Zn-based hybrid materials based on NMR studies. The present work is devoted to the crystal growth, DSC, TGA, and NMR spectroscopy of the  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  compound. The thermal stability at different temperatures was considered. The cation dynamics in a layered perovskite-type  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  single crystal were investigated as a function of temperature by  $^1\text{H}$  MAS NMR,  $^{13}\text{C}$  CP/MAS NMR, and  $^{14}\text{N}$  static NMR experiments. There was no jump in  $T_{1\rho}$  across the phase transition at  $T_{\text{C}3}$  and  $T_{\text{C}4}$ , while  $T_{1\rho}$  showed a slight jump at  $T_{\text{C}2}$ . To obtain detailed information about the cation dynamics of this crystal, the spin-lattice relaxation time  $T_{1\rho}$  in the rotating frame for both  $^1\text{H}$  and  $^{13}\text{C}$  were obtained, revealing that these atoms undergo rotational motions. The BPP curves for the  $^1\text{H}$   $T_{1\rho}$  in  $\text{C}_2\text{H}_5\text{NH}_3$  cation and for the  $^{13}\text{C}$   $T_{1\rho}$  in  $\text{C}_2\text{H}_5$  were shown to have minima as a function of inverse temperature. This implies that these curves represent the rotational motions of  $^1\text{H}$  and  $^{13}\text{C}$ . The activation energy for  $^1\text{H}$  in the  $\text{C}_2\text{H}_5\text{NH}_3$  cation is  $E_a = 39.41 \text{ kJ mol}^{-1}$  above 290 K and  $57.59 \text{ kJ mol}^{-1}$  below 290 K, whereas that for  $^{13}\text{C}$  in the  $\text{C}_2\text{H}_5\text{NH}_3$  cation is  $21.13 \text{ kJ mol}^{-1}$ . Furthermore, the carbon dynamics of  $\text{C}_2\text{H}_5$  undergo rotation slower than protons. This implies that molecular motion is enhanced at the carbon-end and nitrogen-end of the organic cation, whereas molecular motion is not free at the main chain carbons of the organic cation.

Moreover, we compared the phase transition temperatures and molecular motions of the previously reported  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{CuCl}_4$  (ref. 23) and those of  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  studied here. The difference between these compounds is only the inorganic cation.  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  and  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{CuCl}_4$  are characterized by five (231, 234, 237, 247, and 312 K) and four (236, 330, 357, and 371 K) phase transitions, respectively. Furthermore, the molecular motions affecting the spin-lattice relaxation time  $T_{1\rho}$  in  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  are very different from those for  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{CuCl}_4$ . The activation energies obtained from  $T_{1\rho}$  by the  $^1\text{H}$  and  $^{13}\text{C}$  measurements for the two compounds are summarized in Table 1. The  $E_a$  for  $^1\text{H}$  in  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  are the values at high temperatures above 290 K and the low temperatures below 290 K, respectively. In the case of  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{CuCl}_4$ ,  $E_a$  for each  $\text{C}_2\text{H}_5$  and  $\text{NH}_3$  is shown at a temperature range from 180 K to 240 K.<sup>23</sup> The values of  $E_a$  obtained from the  $^1\text{H}$  measurements of  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  are larger than those of  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{CuCl}_4$ , whereas those obtained from the  $^{13}\text{C}$  measurements are similar. These results indicate that the activation energies obtained from the  $^1\text{H}$  measurements for the H-Cl-Zn bond in  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  without the paramagnetic ions

Table 1 Activation energies,  $E_a$  ( $\text{kJ mol}^{-1}$ ) for  $^1\text{H}$  and  $^{13}\text{C}$  nuclei in  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$  and  $(\text{C}_2\text{H}_5\text{NH}_3)_2\text{CuCl}_4$

	$(\text{C}_2\text{H}_5\text{NH}_3)_2\text{ZnCl}_4$	$(\text{C}_2\text{H}_5\text{NH}_3)_2\text{CuCl}_4$ (ref. 23)
$^1\text{H}$	$39.41 \pm 1.56$ (for all hydrogen above 290 K)	$12.19 \pm 1.30$ (for $\text{C}_2\text{H}_5$ below 240 K)
$^1\text{H}$	$57.59 \pm 2.96$ (for all hydrogen below 290 K)	$8.33 \pm 0.50$ (for $\text{NH}_3$ below 240 K)
$^{13}\text{C}$	$21.13 \pm 1.27$ (for $\text{C}_2\text{H}_5$ )	$21.35 \pm 0.45$ (for $\text{CH}_3$ )
$^{13}\text{C}$		$19.72 \pm 1.76$ (for $\text{CH}_2$ )

is larger than that for the H–Cl–Cu bond in  $(C_2H_5NH_3)_2CuCl_4$  including paramagnetic ions. These differences are due to the differences in the electronic structure of the  $Zn^{2+}$  and  $Cu^{2+}$  ions, particularly, the d electrons, which screen the nuclear charge from the motion of the outer electrons.  $Zn^{2+}$  has filled d shell, whereas  $Cu^{2+}$  has one s electron outside the closed d shell. It is also likely due to several other factors, such as different coordination of the metal atom, different lattice constants, and hydrogen bonding strength. This suggests that the differences in the chemical properties of metal ions are responsible for the variations in the characteristics of the phase transitions and molecular motions in these crystals. This study can motivate us to find a solution for improving the material features as well as solar cell performance using lead-free perovskites based on Zn or Cu in market-competitive optoelectronic materials for photovoltaics (PV) and light emitting diodes (LED) applications.<sup>3,24,25</sup>
