Double-layer carbon protected CoS₂ nanoparticles as an advanced anode for sodium-ion batteries†

Xiang Yao, Hui Cheng, Yuping Huang, Zhouyang Jiang, Qingyue Han and Suqing Wang *

Cobalt disulfides with high theoretical capacity are regarded as appropriate anode materials for sodium ion batteries (SIBs), but their intrinsically low conductivity and large volume expansion lead to a poor electrochemical performance. In this work, graphitic carbon coated CoS₂ nanoparticles are encapsulated in bamboo-like carbon nanotubes by pyrolysis and sulfidation process. Graphitic carbon can improve the electrical conductivity and prevent the agglomeration of CoS₂ nanoparticles. Meanwhile, bamboo-like carbon nanotubes can serve as conductive skeleton frames to provide rapid and constant transport pathways for electrons and offer void space to buffer the volume change of CoS₂ nanoparticles. The advanced anode material exhibits a long-term capacity of 432.6 mA h g⁻¹ at 5 A g⁻¹ after 900 cycles and a rate capability of 419.6 mA h g⁻¹ even at 10 A g⁻¹ in the carbonate ester-based electrolyte. This avenue can be applicable for preparing other metal sulfide/carbon anode materials for sodium-ion batteries.

Introduction

The energy shortage and environmental pollution have disrupted global development. Renewable energy has been urgently used to substitute fossil fuel. Although lithium-ion batteries (LIBs) and lithium metal batteries (LMBs) have been developed in fundamental research as an industrial application, the fewer lithium resources on Earth and hence their high cost restrict the long-term usage of LIBs.^{1–3} However, sodium-ion batteries (SIBs) have lowered the concerns, thanks to the abundant sodium sources and cheaper sodium salt.^{4,5} On the other hand, commercial graphite anode is not suitable for SIBs because its interlayer spacing is smaller than the diameter of Na⁺.^{6,7} Thus, exploring suitable anode materials is urgently required for SIBs. In contrast to transition metal oxides, transition metal sulfides are kinetically favorable for conversion reactions, which makes them have more potential with other anode materials.^{8,9} Furthermore, they possess high specific capacity and easily-controlled morphology and are regarded as prospective anode materials for SIBs.¹⁰ More importantly, compared with other cobalt sulfides (CoS, Co₃S₄, and Co₉S₈),¹¹ CoS₂ has a great advantage in virtue of high theoretical capacity of 872 mA h g⁻¹ because of a four-electron conversion reaction represented as CoS₂ + 4Na⁺ + 4e⁻ ↔ Co + 2Na₂S.¹² Owing to the drastic volume change of conversion-type mechanism, CoS₂ always exhibits

a poor cycling performance.¹³ Numerous researches have been dedicated to mitigate the issue. Downsizing the particle size is one common way to decrease the length of ion diffusion and relieve the pressure of volume expansion.¹⁴ Liu *et al.* reported that CoS₂ with hollow microstructures was used as an anode for SIBs, which retained 690 mA h g⁻¹ at 1 A g⁻¹ after 100 cycles.¹⁵ Another effective way is to incorporate CoS₂ particles with a carbon material, which can not only provide electron transport pathways but also buffer volume expansion. Zhang *et al.* revealed the production of CoS₂ nanoparticles with a spongy carbon matrix and also stated that the SIB anode material displayed a rate capability of 330 mA h g⁻¹ at 0.5 A g⁻¹ after 60 cycles.¹⁶ Cheng *et al.* bound nanosized CoS₂ in graphene and the material could retain 394 mA h g⁻¹ at 1 A g⁻¹ after 2500 cycles, which can be attributed to the highly conductive graphene network and short diffusion length of electrons and ions within the electrode.¹⁷ Xie *et al.* displayed the preparation of CoS₂ nanoparticles enclosed in rGO, and the material can reach to about 400 mA h g⁻¹ at 0.1 A g⁻¹ after 100 cycles.¹⁸ These studies suggested that a reasonable electrode structure design and incorporation of CoS₂ nanoparticles with a carbon material can exhibit good sodium storage performance. However, an unstable structure of electrode in carbon material and serious side effects of nanoparticles and electrolyte could impair the performance of CoS₂.^{19–21}

Here, we prepared a double-layered carbon structure as the anode material in which graphitic carbon-coated CoS₂ nanoparticles were encapsulated in bamboo-like carbon nanotubes (CoS₂@GC@B-CNT). In this preparation, graphitic carbon (GC) could serve as an appropriate coating layer because the electrical conductivity of GC is higher than that of amorphous

School of Chemistry and Chemical Engineering, Guangdong Provincial Key Lab of Green Chemical Product Technology, South China University of Technology, Guangzhou 510640, P. R. China. E-mail: cesqwang@scut.edu.cn

carbon layers and the GC layer can prevent the agglomeration of CoS_2 nanoparticles. Furthermore, bamboo-like carbon nanotubes (B-CNTs) serve as conductive skeleton frames to provide continuous and fast transport pathways for electrons and offer sufficient voids to buffer the volume expansion of CoS_2 nanoparticles, which could maintain a steady structure during the sodiation/desodiation process. Therefore, the obtained $\text{CoS}_2@\text{GC}@B\text{-CNT}$ showed excellent long-term cycling performance and high rate capability when used as an anode in a carbonate ester-based electrolyte for SIBs.

Experimental

Material synthesis

The $\text{CoS}_2@\text{GC}@B\text{-CNT}$ samples were obtained by a two-step formation process. First, cobalt nitrate hexahydrate (0.8 g), glucose (0.1 g) and melamine (8.0 g) were blended together in 50 mL deionized water under stirring for 1 h. The solution was dried at 80 °C for 1 h and annealed at 800 °C for 2 h in Ar gas to produce $\text{Co}@GC@B\text{-CNT}$. Then, 0.1 g of $\text{Co}@GC@B\text{-CNT}$ and an appropriate amount of thiourea were placed in two separate crucible boats and treated at 450 °C for 4 h with thiourea at the upstream side in the pipe furnace under Ar atmosphere. In order to prepare B-CNT, the $\text{CoS}_2@\text{GC}@B\text{-CNT}$ samples were treated in 6.0 M HCl solution for 8 h under stirring, washed by deionized water, and dried at 80 °C for 12 h. To gain bare CoS_2 , 1.0 g of cobalt nitrate hexahydrate and an appropriate amount of thiourea powder were annealed by the same protocol as for the synthesis of $\text{CoS}_2@\text{GC}@B\text{-CNT}$. For the CoS_2/CNT composite, 0.0581 g CoS_2 was mixed with 0.0419 g commercial multi-walled carbon nanotube.

Material characterization

The structures were detected through an XRD (Bruker D8 Advanced) operated within the 2θ range of 10–70°. The percentage of carbon in $\text{CoS}_2@\text{GC}@B\text{-CNT}$ was measured by Thermogravimetric Analysis. The samples were oxidized and annealed from 30 to 850 °C in air by a TG equipment (NETZSCH STA44C). The morphology was studied by SEM (HITACHI-SU8220) and TEM (JEM-2100F) with an EDS elemental mapping. XPS was tested by an ESCALAB 250 X-ray photoelectron spectrometer. N_2 adsorption/desorption experiments were performed on a Micromeritics Analyzer ASAP 2460 equipment.

Electrochemical tests

The anode electrodes were obtained by mixing the active material, Super-P and polyvinylidene fluoride (8 : 1 : 1 by weight). The slurry was coated on a Cu foil and dried in a vacuum oven at 80 °C for 12 h. The mass loading of active materials based on the total weight of CoS_2 and carbon was about 1.0–1.5 mg cm^{-2} . The separator was a Whatman (GF/B) glass fiber. The electrolyte was 1 M NaClO_4 in a mixture of ethylene carbonate and diethyl carbonate (v/v = 1 : 1) with 5 wt% fluoroethylene carbonate. Sodium discs were the opposite electrode. Coin cells (CR 2032) were fabricated in an Ar-filled glovebox. Constant current charge/discharge

Scheme 1 Schematic illustration of the preparation of $\text{CoS}_2@\text{GC}@B\text{-CNT}$.

measurements were checked on a battery test station (Neware Electronic Co.) from 0.01 to 3.00 V. CV was performed on an electrochemical workstation (CHI760D) between 0.01 and 3.00 V at a scan rate of 0.2 mV s^{-1} . EIS was performed at frequencies ranging from 0.01 to 0.1 MHz.

Results and discussion

The $\text{CoS}_2@\text{GC}@B\text{-CNT}$ anode material was obtained by a two-step formation process (Scheme 1). In the first step, cobalt nitrate hexahydrate, glucose, and melamine were annealed at 800 °C to produce $\text{Co}@GC@B\text{-CNT}$. The XRD pattern is displayed in Fig. 1a, in which the diffraction peaks are in good accordance with metallic Co. Then, $\text{CoS}_2@\text{GC}@B\text{-CNT}$ was acquired after thermal treatment *via* a sulfidation process. From the XRD pattern of $\text{CoS}_2@\text{GC}@B\text{-CNT}$ (Fig. 2a), the major peaks of $\text{CoS}_2@\text{GC}@B\text{-CNT}$ corresponded to CoS_2 . The wide diffraction peak at 26.1° is observed and corresponds to the (002) plane of graphite. The morphology of the carbon nanotubes is unchanged before and after the sulfidation process (Fig. 1b and 2b). The TEM images confirm that CoS_2 nanoparticles are completely encapsulated in B-CNT (Fig. 2c and d) and the void in the B-CNT could buffer the volume change of CoS_2 in the course of the conversion reaction. Furthermore, B-CNT could provide facile electronic and ionic transport, improving the conductivity of the material. Fig. 2e shows that the CoS_2 nanoparticles are surrounded by GC, and the lattice spacing of 0.247 and 0.226 nm associate with the interplanar distance of the (210) and (211) planes, respectively. In the meantime, the lattice spacing of 0.35 nm ascribes to the interplanar distance of the (002) plane of carbon. The GC originating from the catalysis of Co nanocrystals during the thermal treatment can improve the electrical conductivity and prevent the agglomeration of CoS_2 nanoparticles.^{22–25} The elemental mapping images (Fig. 2f) further demonstrate that

Fig. 2 (a) XRD pattern of the CoS₂@GC@B-CNT; (b) SEM and (c) TEM images of the CoS₂@GC@B-CNT; (d) TEM and (e) HR-TEM images of the CoS₂@GC@B-CNT; (f) TEM image of CoS₂@GC@B-CNT and the element mapping images.

while the peak at 164.8 eV is contributed by S 2p_{1/2}.²⁸ The C 1s spectrum includes two fitting peaks (Fig. 5c); they are C-C (284.8 eV) and C-N (285.8 eV).^{29,30} On the basis of XPS analysis, it can be confirmed that CoS₂ nanoparticles have been favorably prepared, which is unanimous in the previous XRD and TEM analyses. Fig. 5d shows that the N 1s spectrum evinces the attendance of pyridinic (399.3 eV), pyrrolic (400.0 eV) and graphitic (401.9 eV) types of N. N doping could introduce more defective sites, which boost the sodium storage performance.³¹

The CV test of CoS₂@GC@B-CNT was conducted at 0.2 mV s⁻¹ (Fig. S3†). The oxidation and reduction peaks are presented in the first cycle. The oxidation peaks are put down to the production of Na_xCoS₂ and CoS₂. Moreover, the reduction peaks in the first cycle are different from those in the later cycles, which mainly ascribes to the activation process. In the second and third cycles, the peaks (0.89 and 1.36 V) stem from the conversion reaction (CoS₂ + 4Na → Co + 2Na₂S) and the peak at 0.52 V implies that Na⁺ intercalates into the GC. Fig. 6a displays first three charge and discharge curves. CoS₂@GC@B-CNT delivers a reversible capacity of about 550 mA h g⁻¹ at 0.1 A g⁻¹. To clarify the capacity contribution of B-CNT, CoS₂@GC@B-CNT was treated by an acid to remove CoS₂. The XRD pattern (Fig. S4a†) shows that most of the CoS₂ particles were removed by HCl and the morphology of the carbon nanotubes is not varied (Fig. S4b†). The electrochemical

Fig. 6 (a) First three charge/discharge curves of $\text{CoS}_2\text{@GC@B-CNT}$ electrode at 0.1 A g^{-1} ; (b) cycle performance of $\text{CoS}_2\text{@GC@B-CNT}$ electrode at 0.1 A g^{-1} ; (c) rate capability and (d) charge/discharge curves of $\text{CoS}_2\text{@GC@B-CNT}$ electrode recorded at different rates; (e) long-term cycling performance at 5 A g^{-1} .

performance of individual B-CNT was measured at 0.1 A g^{-1} (Fig. S4c and d†); the capacity was approximately 150 mA h g^{-1} during 100 cycles. The carbon content of $\text{CoS}_2\text{@GC@B-CNT}$ is 41.9% (Fig. 3). Through calculation, the capacity contribution of carbon is about 62 mA h g^{-1} , which indicates that the main capacity of $\text{CoS}_2\text{@GC@B-CNT}$ is contributed to CoS_2 . In Fig. 6b and S5†, the cycling performances of $\text{CoS}_2\text{@GC@B-CNT}$, CoS_2/CNT and bare CoS_2 are measured at 0.1 A g^{-1} . It is obvious that the cycling stability of $\text{CoS}_2\text{@GC@B-CNT}$ is the best among them. The CoS_2/CNT and bare CoS_2 present significant capacity fading during cycling, which indicates that CoS_2 is the main capacity source of $\text{CoS}_2\text{@GC@B-CNT}$.

Fig. 6c shows the rate performance of $\text{CoS}_2\text{@GC@B-CNT}$. $\text{CoS}_2\text{@GC@B-CNT}$ shows the discharge capacities of 564.3, 518.5, 486.5, 471.0, 455.9, 438.0, 419.6 mA h g^{-1} at the rates of 0.1, 0.2, 0.5, 1, 2, 5 and 10 A g^{-1} , respectively. The $\text{CoS}_2\text{@GC@B-CNT}$ electrode can hold $512.6 \text{ mA h g}^{-1}$ at 0.1 A g^{-1} . Fig. 6d displays the relevant charge and discharge curves of $\text{CoS}_2\text{@GC@B-CNT}$, which suggests its superior rate capability. In contrast, CoS_2/CNT and bare CoS_2 electrodes show much lower capacities (Fig. S6†). The CoS_2/CNT and bare CoS_2 samples retained capacities of 58.9 and 36.2 mA h g^{-1} at 1 A g^{-1} , respectively. Fig. 6e exhibits a long-term cycling property of $\text{CoS}_2\text{@GC@B-CNT}$, which demonstrates a capacity of $432.6 \text{ mA h g}^{-1}$ after 900 cycles at 5 A g^{-1} and the capacity retention of 95.9%. In particular, the electrochemical

Fig. 7 Nyquist plots of the $\text{CoS}_2\text{@GC@B-CNT}$ electrode.

property of $\text{CoS}_2\text{@GC@B-CNT}$ is eminent among other cobalt sulfide-based electrodes in the carbonate ester-based electrolyte for SIBs (Table S1†). The outstanding electrochemical performance is ascribed to the novel structure design of $\text{CoS}_2\text{@GC@B-CNT}$. The synergetic actions of GC and B-CNT can improve the electrical conductivity, prevent the particle agglomeration and maintain structural stability of $\text{CoS}_2\text{@GC@B-CNT}$ during the sodiation/desodiation process. The EIS tests were investigated before and after different numbers of cycles. The Nyquist plots of the $\text{CoS}_2\text{@GC@B-CNT}$ electrode exhibit a semicircle and a following linear slope (Fig. 7). The semicircle region ascribes to the charge transfer resistance (R_{ct}).³² The R_{ct} decreases after 50 cycles. Furthermore, after 100 cycles, the R_{ct} displays just a small increase, suggesting a stable structure and good conductivity of the electrode.^{33,34} The reason can be ascribed to the composite electrode decorated with GC and B-CNT.

To investigate the cause of the good cycling stability of $\text{CoS}_2\text{@GC@B-CNT}$ electrode, the cells were disassembled at 0.1 A g^{-1} after 100 cycles. The $\text{CoS}_2\text{@GC@B-CNT}$ sustains

Fig. 8 (a) SEM image of $\text{CoS}_2\text{@GC@B-CNT}$ after 100 cycles; (b) TEM and (c) HR-TEM images of $\text{CoS}_2\text{@GC@B-CNT}$ after 100 cycles; (d) TEM image of $\text{CoS}_2\text{@GC@B-CNT}$ after 100 cycles and the corresponding element mapping images.

structural integrity (Fig. 8a), further confirming the outstanding cycling performance of CoS₂@GC@B-CNT. The detailed inner structure is shown in Fig. 8b where the CoS₂ nanoparticles are encapsulated in B-CNT. Fig. 8c displays that the CoS₂ nanoparticles are still surrounded by GC, which confirms that GC is stable during the charge/discharge process. Therefore, high stability is observed due to the double protection of GC and B-CNT. The elemental mapping images give the elemental distribution of Co, S, and C, which indicates that the CoS₂ particles are still encapsulated in B-CNT (Fig. 8d). In contrast, CoS₂/CNT and bare CoS₂ present large volume expansion during the sodiation/desodiation process (Fig. S7[†]), which results in poor electrochemical properties.

Conclusions

In summary, CoS₂@GC@B-CNT was successfully synthesized by pyrolysis and sulfidation process. Double-layer carbon can improve the electrical conductivity and maintain structural stability during the sodiation/desodiation process, which can enhance electrochemical performances. CoS₂@GC@B-CNT displayed a high rate capability of 419.6 mA h g⁻¹ at 10 A g⁻¹ and eminent long-term cycling performance with 95.9% capacity retention at 5 A g⁻¹ after 900 cycles. This avenue could be widely applied for preparing other anode materials using metal sulfides and carbon for high-performance SIBs.
