# Low-temperature selective catalytic reduction of NO<sub>x</sub> with NH<sub>3</sub> over an activated carbon-carbon nanotube composite material prepared by *in situ* method†

Pengchen Wang,<sup>a</sup> Lu Yao,<sup>a</sup> \*<sup>a</sup> Yijuan Pu,<sup>b</sup> Lin Yang,<sup>ab</sup> Xia Jiang <sup>ab</sup> and Wenju Jiang<sup>\*ab</sup>

Ce-supported activated carbon-carbon nanotube composite (Ce/AC-CNTs) catalyst was prepared by *in situ* formation of CNTs on AC and then modified by Ce. This Ce/AC-CNTs catalyst was subsequently used for low-temperature selective catalytic reduction of NO<sub>x</sub> with NH<sub>3</sub> (NH<sub>3</sub>-SCR). The NO conversion of Ce/AC-CNTs was 1.41 times higher than that of Ce/AC at 150 °C with good SO<sub>2</sub> tolerance. The catalysts were analyzed by N<sub>2</sub> physisorption, SEM, XRD, NH<sub>3</sub>-TPD, XPS, and Raman technologies. The results showed that the introduction of CNTs could form new mesopores and increase the amount of surface chemisorbed oxygen and acid sites, which all contribute to the high NH<sub>3</sub>-SCR activity.

## 1. Introduction

Nitrogen oxides (NO<sub>x</sub>) originating from fossil fuel combustion have caused serious environmental pollution problems, such as photochemical smog, acid rain, ozone layer depletion, and even global warming.<sup>1,2</sup> Among various denitrification technologies the selective catalytic reduction of NO<sub>x</sub> with NH<sub>3</sub> (NH<sub>3</sub>-SCR) is the most successful and widely applied technology.<sup>3,4</sup> The V<sub>2</sub>O<sub>5</sub>-WO<sub>3</sub>(MoO<sub>3</sub>)/TiO<sub>2</sub> catalyst is used as a typical commercial NH<sub>3</sub>-SCR catalyst which works at relatively high temperatures (300–400 °C).<sup>5,6</sup> However, some inevitable disadvantages of the commercial catalysts, such as the narrow operation temperature window and the poor low-temperature catalytic activity, are still observed.<sup>7,8</sup> Therefore, developing an efficient catalyst for low temperature NH<sub>3</sub>-SCR reaction is highly desirable.

Activated carbon (AC) have been widely used as the support for NH<sub>3</sub>-SCR catalysts due to its low price and developed porous structure.<sup>9</sup> Wang *et al.* found that the CeMn/AC catalyst showed 44% NO removal efficiency at 160 °C.<sup>10</sup> Jing *et al.* reported that the V<sub>2</sub>O<sub>5</sub>/AC exhibited 60% NO conversion at 150 °C.<sup>11</sup> However, the AC-catalysts were easily deactivation in the presence of SO<sub>2</sub>.<sup>12</sup> Therefore, further efforts should be carried out to improve SO<sub>2</sub> resistance of SCR catalysts.

Carbon nanotubes (CNTs) were used as support for NH<sub>3</sub>-SCR reaction in recent years due to their high adsorbability for NO<sub>x</sub> and NH<sub>3</sub>.<sup>13</sup> Besides, NO could even be decomposed directly over CNTs,<sup>14</sup> and importantly, the CNTs-catalyst presented good SO<sub>2</sub> and water resistance.<sup>15</sup> Luo *et al.* found that NO can be 100% decomposed at 600 °C on CNTs.<sup>16</sup> Bai *et al.* reported that the NO conversion of V<sub>2</sub>O<sub>5</sub>/CNTs (50%) was higher than that on V<sub>2</sub>O<sub>5</sub>/AC (38%) at 250 °C, and V<sub>2</sub>O<sub>5</sub>/CNTs also had a better SO<sub>2</sub> resistance compared with V<sub>2</sub>O<sub>5</sub>/AC.<sup>17</sup> Cai *et al.* found that the catalytic activity of Fe@Mn@CNTs is barely affected by the SO<sub>2</sub> and exhibits an over 85% NO conversion temperature window from 150 to 270 °C.<sup>18</sup> Santillan-Jimenez *et al.* investigated the existence of H<sub>2</sub>O and noted slight inhibitory effects on the catalytic activity of the SCR catalyst when CNTs were used as the support.<sup>19</sup> Thus, considering of the cost and catalytic performance, an activated carbon-carbon nanotubes composite (AC-CNTs) was used for NH<sub>3</sub>-SCR reaction.

Due to the low dispersion and self-aggregation property of carbon nanotubes, it is difficult to get carbon nanotubes into AC by mechanical mixing method.<sup>20</sup> Su *et al.* successfully prepared AC-CNT (CNF) composite by treating the Fe/AC catalyst in flowing C<sub>2</sub>H<sub>4</sub>/H<sub>2</sub>.<sup>21</sup> Chen *et al.* also found that the CNTs were successfully grew on Fe-deposited Si substrate *via* the chemical vapor deposition method using a CH<sub>4</sub>-CO<sub>2</sub> gas mixture.<sup>22</sup> However, the use of AC-CNTs composites in the NH<sub>3</sub>-SCR reaction has not been reported.

In this work, an AC-CNTs composite was prepared *via* CH<sub>4</sub> decomposition on AC. Then the Ce/AC-CNTs catalysts were obtained by an impregnation method. This work aims to combine the advantages of CNTs and AC and used the Ce/AC-CNTs catalyst for NH<sub>3</sub>-SCR reaction at low temperature. The

physicochemical properties of catalysts were also comprehensively discussed in the present work.

## 2. Materials and methods

### 2.1 Materials

The AC (C 78.68%, N 0.27%, O 18.59%, and H 2.46%) was used as the precursor to prepare activated carbon-CNTs (AC-CNTs) bought from Xinhua Activated Carbon Co., Ltd. The agents used in this study, such as  $\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  and  $\text{Ce}(\text{NO}_3)_3 \cdot 6\text{H}_2\text{O}$ , were of analytical reagent grade (AR) and purchased from Chengdu Chron Chemicals Co., Ltd.

### 2.2 Preparation of catalysts

The AC-CNTs were prepared *via in situ* formation of CNTs (by methane decomposition) on AC. First, AC was impregnated with a certain amount of  $\text{Ni}(\text{NO}_3)_2$  solution for 24 h at 25 °C and then dried at 80 °C for 12 h to obtain the Ni/AC precursor, which was the catalyst of methane decomposition. Subsequently, the obtained sample was pretreated at 750 °C under  $\text{N}_2$  flow for 2 h, and then, cooled to 650 °C (with switching to  $\text{CH}_4$  atmosphere) for 30 min to produce CNTs on AC (AC-CNTs). The obtained sample was named AC-CNTs. The AC and AC-CNTs impregnated with the  $\text{Ce}(\text{NO}_3)_3$  solution and calcined at 450 °C for 6 h under  $\text{N}_2$  atmosphere were denoted as Ce/AC and Ce/AC-CNTs, respectively.

### 2.3 Denitrification test

$\text{NH}_3$ -SCR experiments of the prepared samples were performed in a fixed-bed quartz tube reactor with an internal diameter of 10 mm. The reaction temperature and space velocity (GHSV) was 150 °C and 50 000  $\text{h}^{-1}$ , respectively. The total flow rate of gas was 500  $\text{mL min}^{-1}$ , and the typical reactant gas contained 500 ppm of  $\text{NO}$ , 550 ppm of  $\text{NH}_3$ , 5 vol% of  $\text{O}_2$ , 50 ppm ( $142.8 \text{ mg m}^{-3}$ ) of  $\text{SO}_2$  (when used), 10 vol% of  $\text{H}_2\text{O}$  (when used), and balance of  $\text{N}_2$ . A flue gas analyzer (Gasboard-3000, Wuhan Cubic Optoelectronics Co., Ltd., CN) was used to determine the inlet and outlet  $\text{NO}$  concentrations online. The  $\text{NO}$  reduction with  $\text{NH}_3$  of all samples was beginning (was started) at the  $\text{NO}$  saturated sample under the same denitrification condition to eliminate the adsorption effect of  $\text{NO}$ .

### 2.4 Characterization of adsorbents

$\text{N}_2$  adsorption-desorption experiments of the prepared samples were measured at 77 K using the ASAP 2460 instrument (Micromeritics Instrument Co., Ltd., USA). The specific surface area ( $S_{\text{BET}}$ ), total pore volume ( $V_{\text{tot}}$ ), mesopore volume ( $V_{\text{mes}}$ ), micropore volume ( $V_{\text{mic}}$ ), and pore size distribution were obtained from the  $\text{N}_2$  adsorption-desorption isotherms by using the Brunauer-Emmett-Teller (BET) equation,  $\text{N}_2$  adsorption amount at the maximum relative pressure, Barrett-Joyner-Halenda method,  $t$ -plot method, and density functional theory method, respectively. The surface morphology of samples was observed microscopically *via* scanning electron microscopy (SEM, JSM-7500F, Jeol Co., Ltd., Japan).

The crystal structure of AC was analyzed by X-ray diffraction using an X'Pert PRO MPD diffractometer (Panalytical Co., Ltd., Netherlands). The crystalline phases were identified by comparison with the reference data from the International Center for Diffraction Data (JCPDs).

The  $\text{NH}_3$ -temperature-programming desorption ( $\text{NH}_3$ -TPD) was conducted on a TP-5076 chemisorption analyzer (Tianjin First Industry and Trade Development Co. Ltd., CN). The samples were pretreated at 400 °C in a He flow for 1 h. Subsequently, the samples were cooled down to 30 °C and saturated with  $\text{NH}_3$  until adsorption equilibrium was reached, followed by blowing with He at the same temperature to avoid  $\text{NH}_3$  physisorption. The saturated samples were then heated from 30 °C to 800 °C at a rate of 10 °C  $\text{min}^{-1}$  in He.

The surface chemistry was determined by X-ray photoelectron spectroscopy using an XSAM-800 spectrometer (Kratos Co., Ltd., UK) with light as the mono Al  $K\alpha$  (1486.6 eV). Raman spectra were collected by a Raman spectrometer (LabRAM-HR, Horiba Co., Ltd., Japan). The wavelength and power were 532 nm and 5 mW, respectively, while the spectral resolution was  $\pm 1 \text{ cm}^{-1}$ .

## 3. Results and discussion

### 3.1 Catalyst characterization

**3.1.1 Textural properties.** Fig. 1 shows loose and porous structures of the AC surface. After the introduction of CNTs, distinct CNTs were observed on the surface of AC-CNTs with a length distribution of approximately 100–300 nm and diameter of 10–30 nm.

$\text{N}_2$  adsorption-desorption isotherms and textural properties of the prepared samples are shown in Fig. S1 (seen in ESI<sup>†</sup>) and Table 1, respectively. The BET surface area of the catalysts varied as follows: AC ( $803 \text{ m}^2 \text{ g}^{-1}$ ) > AC-CNTs ( $774 \text{ m}^2 \text{ g}^{-1}$ ) > Ce/AC ( $700 \text{ m}^2 \text{ g}^{-1}$ ) > Ce/AC-CNTs ( $599 \text{ m}^2 \text{ g}^{-1}$ ). Notably, the  $V_{\text{mic}}$  evidently decreased after the introduction of CNTs. The  $V_{\text{mic}}$  of AC and Ce/AC was 0.28 and 0.24  $\text{cm}^3 \text{ g}^{-1}$  while that of AC-CNTs and Ce/AC-CNTs decreased to 0.24 and 0.17  $\text{cm}^3 \text{ g}^{-1}$ , respectively, after CNTs introduction. However, the  $V_{\text{mes}}$  of the catalyst displayed an opposite trend to that of  $V_{\text{mic}}$ . The  $V_{\text{mes}}$  of AC and Ce/AC was 0.24 and 0.19  $\text{cm}^3 \text{ g}^{-1}$  while that of AC-CNTs and Ce/AC-CNTs increased to 0.31 and 0.22  $\text{cm}^3 \text{ g}^{-1}$ , respectively, after CNTs introduction. Furthermore, the  $V_{\text{mic}}/V_{\text{tot}}$  and average pore size decreased, while the  $V_{\text{mes}}/V_{\text{tot}}$  increased after CNTs introduction. These results suggested that pore blockage occurred to

Fig. 1 SEM images of (a) AC and (b) AC-CNTs.

Table 1 Textural structure parameters of prepared samples<sup>a</sup>

Catalyst	$S_{\text{BET}}$ ( $\text{m}^2 \text{g}^{-1}$ )	$V_{\text{tot}}$ ( $\text{cm}^3 \text{g}^{-1}$ )	$V_{\text{mic}}$ ( $\text{cm}^3 \text{g}^{-1}$ )	$V_{\text{mes}}$ ( $\text{cm}^3 \text{g}^{-1}$ )	$V_{\text{mic}}/V_{\text{tot}}$ (%)	$V_{\text{mes}}/V_{\text{tot}}$ (%)	$D_{\text{mean}}$ (nm)
AC	803	0.57	0.28	0.24	48.2	41.4	6.42
AC-CNTs	774	0.58	0.24	0.31	41.5	53.6	3.00
Ce/AC	700	0.48	0.24	0.19	50.6	39.8	6.32
Ce/AC-CNTs	599	0.43	0.17	0.22	39.5	51.1	5.22

<sup>a</sup>  $S_{\text{BET}}$ , BET surface area;  $V_{\text{tot}}$ , total pore volume;  $V_{\text{mic}}$ , micropore volume;  $V_{\text{mes}}$ , mesopore volume;  $D_{\text{mean}}$ , average pore diameter.

a considerable extent upon the loading of Ce species and formation of CNTs due to the obvious decrease of the  $S_{\text{BET}}$  and  $V_{\text{mic}}$  after the introduction of Ce and CNTs.

Interestingly, the  $V_{\text{mes}}$  of AC increased from  $0.28 \text{ cm}^3 \text{g}^{-1}$  to  $0.31 \text{ cm}^3 \text{g}^{-1}$  for AC after CNT introduction and decreased to  $0.22 \text{ cm}^3 \text{g}^{-1}$  after the further introduction of Ce. This result inferred that the *in situ* formation of CNTs on AC may form some new mesopores on AC-CNTs. Meanwhile, a certain extent of pore blockage occurred on Ce/AC-CNTs after Ce introduction.

Raman spectra were performed to further study the structure of Ce/AC and Ce/AC-CNTs catalysts, and the results are shown in Fig. 2. The two main peaks were at approximately  $1323 \text{ cm}^{-1}$  (D-band) and  $1590 \text{ cm}^{-1}$  (G-band).<sup>23</sup> The D-band of the catalyst was mainly derived from the disordered carbon or amorphous carbon, whereas the G-band was assigned to the well-ordered carbon. The intensity ratio ( $I_{\text{D}}/I_{\text{G}}$ ) of D-band to G-band is an index of the integrity of catalysts.<sup>24</sup> As shown in Fig. 2, the  $I_{\text{D}}/I_{\text{G}}$  of Ce/AC (1.2) was lower than that of Ce/AC-CNTs (1.3). The increased  $I_{\text{D}}/I_{\text{G}}$  of Ce/AC-CNTs was attributed to the generation of new defects and surface functional groups during the CNTs formation (methane decomposition on AC). This result suggested that the introduction of CNTs favored the formation of disordered or defected carbon.

**3.1.2 Surface acidity.** The surface acidity of catalysts is generally one of the key factors for their denitrification performance in the  $\text{NH}_3$ -SCR reaction. The adsorption and activation of  $\text{NH}_3$  species over the catalysts were highly dependent on the surface acidity properties of the catalysts. The  $\text{NH}_3$ -TPD

experiments were conducted to measure the number of acid sites and strength of acid on the surface of Ce/AC and Ce/AC-CNTs catalysts. The  $\text{NH}_3$  desorption temperature and integral area of desorption peaks in  $\text{NH}_3$ -TPD profiles could represent the acid strength and the number of acid sites, respectively. As shown in Fig. S3 (seen in ESI<sup>†</sup>), the Ce/AC and Ce/AC-CNTs catalysts exhibited three desorption peaks during  $50 \text{ }^\circ\text{C}$ - $650 \text{ }^\circ\text{C}$  with the increase in desorption temperature and are denoted as I, II, and III. In the  $\text{NH}_3$ -TPD curves of Ce/AC, the low-temperature desorption peak I centered at approximately  $124 \text{ }^\circ\text{C}$  was attributed to  $\text{NH}_3$  species desorbed from the weak acid sites. Peak II centered at  $179 \text{ }^\circ\text{C}$  was assigned to desorption of  $\text{NH}_3$  species from medium to strong acid sites. Peak III centred at  $377 \text{ }^\circ\text{C}$  was related to strong acid sites.<sup>25</sup> As reported, the  $\text{NH}_4^+$  ions adsorbed on the Lewis acid sites were more thermally stable than those of Brønsted acid sites. Thus, the desorption peak at low temperature of catalysts was ascribed to the  $\text{NH}_4^+$  ions adsorbed on the Brønsted acid sites, while the desorption peak at high temperature was due to  $\text{NH}_3$  molecules originating from the Lewis acid sites.<sup>26</sup>

Ce/AC and Ce/AC-CNTs presented three strong  $\text{NH}_3$  desorption peaks (Fig. S3 in ESI<sup>†</sup>). As shown in Table 2, the quantitative data (from the area of the desorption peak) of  $\text{NH}_3$ -TPD suggested that the relative amount of acid sites on Ce/AC-CNTs ( $19.14 \text{ mmol g}^{-1}$ ) was higher than that of Ce/AC ( $15.80 \text{ mmol g}^{-1}$ ). This result implied that the Ce/AC-CNTs catalyst possessed more acid sites than that of Ce/AC. Moreover, the curve of  $\text{NH}_3$  desorption peaks for Ce/AC-CNTs shifted toward the high temperature region (from  $377 \text{ }^\circ\text{C}$  to  $470 \text{ }^\circ\text{C}$ ). This result demonstrated that the strength of acid sites on Ce/AC-CNTs was stronger than that of Ce/AC. Thus, Lewis acidity was strengthened on Ce/AC-CNTs. As reported, the CNTs could supply strong acid sites, and  $\text{CeO}_2$  supported on CNTs could significantly increase the acidity of CNTs and in favor of the  $\text{NH}_3$ -SCR reaction.<sup>27</sup>

**3.1.3 XPS.** The binding energy and surface atomic composition of Ce/AC and Ce/AC-CNTs were estimated by XPS analysis. Table 3 shows that the relative content of total oxygen of Ce/AC-CNTs was 14.3%, which was higher than that of Ce/AC (11.6%). The ratios of O/C for Ce/AC-CNTs and Ce/AC were 0.17 and 0.13, respectively. Thus, CNTs introduction could promote the formation of surface total oxygen, which could contribute to the high catalytic activity of Ce/AC-CNTs for  $\text{NH}_3$ -SCR reaction; this outcome was in good agreement with the results of Wang.<sup>24</sup>

The O 1s spectra of Ce/AC and Ce/AC-CNTs are exhibited in Fig. S4 (seen in ESI<sup>†</sup>). Three distinct peaks were observed for Ce/

Fig. 2 Comparison of the Raman spectra of Ce/AC and Ce/AC-CNTs.

Table 2 Deconvolution of the NH<sub>3</sub>-TPD profiles of Ce/AC and Ce/AC-CNTs catalysts

Catalyst	Peak temp. (°C)			Relative amount of acid sites (%)			Total desorption amount (mmol g <sup>-1</sup> )
	Peak I	Peak II	Peak III	S I	S II	S III	
Ce/AC	124	179	377	24.9	36.1	39.0	15.80
Ce/AC-CNTs	123	179	470	25.4	36.1	38.5	19.14

Table 3 XPS results of the catalysts

Sample	Ce/AC	Ce/AC-CNTs
C (%)	87	84.2
O (%)	11.6	14.3
O/C	0.13	0.17
Ce (%)	1.5	1.5
(O <sub>β</sub> )/(O <sub>α</sub> + O <sub>β</sub> + O <sub>γ</sub> ) (%)	38.6	42.1

AC and Ce/AC-CNTs. One major peak that appearing at approximately 529.6 eV is assigned to lattice oxygen (O<sup>2-</sup>) (denoted as O<sub>α</sub>). Meanwhile, two peaks that appeared at relatively high binding energy located at approximately 532.3 and 533.8 eV could be assigned to chemisorbed oxygen (denoted as O<sub>β</sub>) and -O- oxygen (denoted as O<sub>γ</sub>).<sup>28</sup> The O<sub>β</sub>, which was the most active oxygen, generally had a strong migration capability, and usually adsorbed on the defective sites of catalysts.<sup>29</sup>

In this study, the relative content of chemisorbed oxygen of Ce/AC-CNTs calculated by O<sub>β</sub>/(O<sub>α</sub> + O<sub>β</sub> + O<sub>γ</sub>) was 42.1%, which was higher than that of Ce/AC (38.6%). As reported, metal oxides, such as CeO<sub>2</sub> and MnO<sub>2</sub>, could increase the electrochemical active surface area of the catalyst.<sup>30</sup> Thus, the introduction of CNTs increased the chemisorbed oxygen and promotion of the electron transfer on the surface of catalyst, these conditions were beneficial to the catalytic activity of Ce/AC-CNTs for the NH<sub>3</sub>-SCR reaction.<sup>31–34</sup>

### 3.2 Catalytic activity

Fig. 3 shows the NO conversions of NH<sub>3</sub>-SCR reaction over different catalysts. The results showed that the NO conversion

Fig. 3 Variation of (a) NO conversion of AC, AC-CNTs, Ce/AC and Ce/AC-CNTs, and (b) SO<sub>2</sub> tolerance and water-resistance of Ce/AC-CNTs over time. Reaction conditions: [NO] = 500 ppm, [NH<sub>3</sub>/NO] = 1.1, [O<sub>2</sub>] = 5 vol%, [SO<sub>2</sub>] = 50 ppm (when used), [H<sub>2</sub>O] = 10 vol% (when used), N<sub>2</sub> balance, reaction temperature = 150 °C and GHSV = 50 000 h<sup>-1</sup>.

(9.4%) over the AC was quite low at 150 °C, whereas the NO conversion over AC-CNTs (<1%) was even lower than that of AC. Moreover, the nickel species on AC-CNTs and Ce/AC-CNTs are mainly in bulk, instead of surface (Table S1 in ESI†), which indicated that the Ni species on catalyst has no obvious effect on denitrification performance. For the Ce-added AC (Ce/AC catalyst), the NO conversion (29.4%) was much higher than that on non-promoted AC (9.4%) due to the presence of the active ceria species. Interesting, compared with Ce/AC, NO conversion evidently improved over Ce/AC-CNTs (41.4%), which was 1.41 times as that of Ce/AC. The effluent gases from stationary sources always contain trace amounts of SO<sub>2</sub> and water vapor, which could have inhibitory effects on the NO<sub>x</sub> removal, especially at low temperature.<sup>35</sup> Thus, SO<sub>2</sub> and water vapor deactivation experiments were performed to clarify the impacts of SO<sub>2</sub> and water vapor on the Ce/AC-CNTs (Fig. 3b). As shown in Fig. 3b, with the absence of SO<sub>2</sub>, the catalyst maintained NO conversion at approximately 41.4%. When 50 ppm of SO<sub>2</sub> was added into the inlet gas, only a slight inhibition effect on NO conversion (decreased by 4.8%) was observed on Ce/AC-CNTs, whereas that of Ce/AC exhibited serious decrease (16.3%) in its NO conversion (Fig. S6 and S7 in ESI†). After the removal of the SO<sub>2</sub> gas, the catalytic activity of Ce/AC-CNTs catalyst was restored to approximately 41.4% as before. Moreover, when H<sub>2</sub>O was added into the inlet gas, the NO conversion of Ce/AC-CNTs decreased by 21.7%, while the NO conversion of Ce/AC decreased by 30.6%.

Furthermore, the NO conversion was rapidly restored to 39.4% when the water vapor supply was turned off. The results indicated the reversible inhibitory effect of water of Ce/AC-CNTs catalyst. The high NO conversion and good SO<sub>2</sub> tolerance of Ce/AC-CNTs suggested that a significant synergistic effect between CeO<sub>2</sub> and CNTs contribute to the NH<sub>3</sub>-SCR reaction.

Table 4 Comparison of NO removal efficiency of various catalysts

Sample	Temperature (°C)	NO removal efficiency (%)	Reference
Ce/AC-CNTs	150	41	This work
Mn-CeO <sub>x</sub> /AC	220	35	3
V <sub>2</sub> O <sub>5</sub> /AC	150	30	36
V-Zr/AC	150	40	16
Mn@CNTs	150	59	37
Fe@Mn@CNTs	90	40	37
Fe-Cu-O/CNTs-TiO <sub>2</sub>	250	12	38
V <sub>2</sub> O <sub>5</sub> /CNT	270	38	32

The comparison of NO removal efficiency with those of literatures have been studied. As it was shown in Table 4, at 150 °C, NO removal efficiency Ce/AC-CNTs (the present work) was 41%, which was higher than reported M/AC (M = metal) catalysts, and even higher than many M/CNTs catalysts. This indicated that the Ce/AC-CNTs catalyst in the present work is competitive for NH<sub>3</sub>-SCR reaction.

## 4. Further discussion

A CNT-promoted-Ce/AC-CNTs catalyst (Ce/AC-CNTs) was prepared by *in situ* formation of CNTs on AC (*via* decomposition of methane) and used for NH<sub>3</sub>-SCR reaction. The catalytic activity of Ce/AC-CNTs catalyst (41.4%) was much higher than that of Ce/AC (29.4%). Although pore blockage occurred to a large extent upon the introduction of CNTs with the decrease in  $S_{\text{BET}}$  and  $V_{\text{mic}}$ , the  $V_{\text{mes}}$  of AC-CNTs and Ce/AC-CNTs increased to 0.07 cm<sup>3</sup> g<sup>-1</sup> and 0.03 cm<sup>3</sup> g<sup>-1</sup> compared with that of AC and Ce/AC, respectively, after the introduction of CNTs. Thus, the *in situ* formation of CNTs on AC formed some new mesopores on AC-CNTs and Ce/AC-CNTs.

CNTs introduction could facilitate the formation of surface total oxygen amount (increasing from 11.6% of Ce/AC to 14.3% of Ce/AC-CNTs) and chemisorbed oxygen (increasing from 38.6% of Ce/AC to 42.1% of Ce/AC-CNTs). The increased amount of chemisorbed oxygen contributes to the high catalytic activity.

CNTs introduction increased the number of acid sites and strengthened the acidity of Ce/AC-CNTs, which enhanced the NH<sub>3</sub> adsorption on catalysts and then improved the SCR catalytic activity. The cost of the AC-CNTs in this work was about 369 Chinese Yuan per kilogram (in laboratory). However, the commercial CNTs (Chengdu Branch Chinese Academy of Science) was 30 000 Chinese Yuan per kilogram, which indicated that the AC-CNTs prepared in this work greatly reduced the cost of catalyst compared to CNTs.

## 5. Conclusions

Ce/AC-CNTs catalyst was prepared by *in situ* formation of CNTs on AC and then modified by Ce, and used for NH<sub>3</sub>-SCR reaction. The NO conversion of Ce/AC-CNTs was 1.41 times higher than that of Ce/AC at 150 °C with good SO<sub>2</sub> tolerance. CNTs introduction could form new mesopores and provide several acid sites, high surface total oxygen, and high surface chemisorption oxygen concentration on Ce/AC-CNTs, resulting in an enhancement of NH<sub>3</sub>-SCR.
