## Rational design of asymmetric supercapacitors via a hierarchical core–shell nanocomposite cathode and biochar anode

Meiqing Fan,<sup>ab</sup> Xu Zeng,<sup>b</sup> Xiaodong Yang,<sup>b</sup> Xin Zhang<sup>b</sup> and Bo Ren<sup>id \*b</sup>

Hierarchical  $\text{MnO}_2$  nanosheets attached on hollow  $\text{NiO}$  microspheres have been designed by a facile hydrothermal process. The core–shell structure is achieved by decorating an  $\text{MnO}_2$  nanosheet shell on a hollow  $\text{NiO}$  sphere core. The highly hollow and porous structure exhibits a high surface area, shortened ion diffusion length, outstanding electrochemical properties ( $558 \text{ F g}^{-1}$  at a current density of  $5 \text{ mA cm}^{-2}$ ), and excellent cycling stability (83% retention after 5000 cycles). To further evaluate the  $\text{NiO}/\text{MnO}_2$  core–shell composite electrode for real applications, three asymmetric supercapacitors ( $\text{NiO}/\text{MnO}_2/\text{pomelo peel}$  (PPC),  $\text{NiO}/\text{MnO}_2/\text{buckwheat hull}$  (BHC), and  $\text{NiO}/\text{MnO}_2/\text{activated carbon}$  (AC)) are assembled. The results demonstrated that  $\text{NiO}/\text{MnO}_2/\text{BHC}$  delivered a substantial energy density ( $20.37 \text{ W h kg}^{-1}$  at a power density of  $133.3 \text{ W kg}^{-1}$ ) and high cycling stability (88% retention after 5000 cycles) within a broad operating potential window of 1.6 V.

## 1. Introduction

Owing to energy depletion, energy storage has become a key technological challenge in the 21st century. Among various emerging energy storage technologies, supercapacitors have attracted great research interest owing to their advantages and potential applications.<sup>1–4</sup> According to the energy storage mechanism, supercapacitors can be classified into two types: electric double-layer capacitors (EDLC) and Faraday pseudocapacitors. Recently, owing to the rapid reversible redox reaction, the specific capacitance has become larger. So, pseudocapacitors are studied by many researchers. Pseudocapacitors can be classified into symmetrical and asymmetric supercapacitors according to the way the positive and negative electrodes store energy. Asymmetric supercapacitors have attracted increasing amounts of attention because they can achieve the highest voltage window of the devices. Generally, transition metal oxides are used as cathodes and carbon materials are used as anodes for asymmetric supercapacitors.

As is well known, electrode materials play a key role in improving the electrochemical properties of the supercapacitors. Transition metal oxides are of special interest owing to their different oxidation states, which play a vital role in the effective transfer of redox charge. Ruthenium oxide ( $\text{RuO}_2$ ) has shown excellent capacitive properties as a supercapacitor electrode with a capacitance as high as  $1300 \text{ F g}^{-1}$ ,<sup>5</sup> but the high

production cost limits its wide application. The applications of cheap metal oxides (such as  $\text{Fe}_2\text{O}_3$ ,<sup>6</sup>  $\text{MnO}_2$ ,<sup>7</sup>  $\text{Co}_3\text{O}_4$ ,<sup>8</sup> and  $\text{NiO}$ )<sup>9</sup> have been widely researched. However, in their application in supercapacitors, each material has its own advantages and disadvantages.  $\text{NiO}$  is considered to be the most promising supercapacitor electrode material and it exhibits many unique properties. However, low ion insertion/release at the electrode/electrolyte interface limits its application.<sup>10</sup> Owing to its wide operating potential window and high theoretical capacity,  $\text{MnO}_2$  has received increasing amounts of research attention. However, its disadvantages are its low surface area and poor electrical conductivity.<sup>11,12</sup> In order to utilize the benefits of metal oxides and overcome their disadvantages, an emerging attractive concept is to study metal oxide composites as electrode materials. For example, Zhao *et al.*<sup>13</sup> prepared a porous composite of  $\text{Mn}_2\text{O}_3/\text{C}@\text{Co}_3\text{O}_4$  by a facile two-step hydrothermal route. The composite showed superior reversible specific capacitance ( $523.8 \text{ F g}^{-1}$  at a current density of  $0.3 \text{ A g}^{-1}$ ) and good cycling stability (90.6% retention after 3000 cycles). Wang *et al.*<sup>14</sup> synthesized  $\text{NiO}@\text{Co}_3\text{O}_4@\text{MnO}_2$  particles via a three-step hydrothermal method. The particles had an excellent specific capacitance ( $792.5 \text{ F g}^{-1}$  at a current density of  $2 \text{ A g}^{-1}$ ) and superior cycling stability (>90% capacity retention after 1000 cycles). Liu *et al.*<sup>15</sup> fabricated a  $\text{NiO}/\text{NiCo}_2\text{O}_4/\text{Co}_3\text{O}_4$  composite by a sol-gel method, which had a high specific surface area and a mesoporous structure. In addition, a large number of studies have shown that the fabricated composite exhibits high specific capacitance and excellent electrochemical stability.<sup>16–18</sup> Carbon materials (carbon,<sup>19</sup> graphene aerogel,<sup>20</sup> graphene,<sup>21</sup> biochar,<sup>22</sup> etc.) are widely used as anode materials in asymmetric supercapacitors. Among them, biochar is attracting

growing attention due to its environmental friendliness, low cost and extensive sources.

In the present work, the NiO/MnO<sub>2</sub> core–shell composite is prepared by a facile method, and the core–shell composite is formed of a MnO<sub>2</sub> nanosheet shell and a hollow NiO sphere core. Research shows that a nanosheet shell decorated on a hollow sphere core can provide highly hollow and porous structures, which can shorten the ion diffusion length and exhibit a high surface area.<sup>23–25</sup> This structural feature is in favour of increasing the electrochemical performance. Furthermore, asymmetric supercapacitors based on a core–shell NiO/MnO<sub>2</sub> cathode and a biochar anode are assembled (Scheme 1). Two types of biochar (pomelo peel (PPC) and buckwheat hull (BHC)) are processed. For comparison, three asymmetric supercapacitors (NiO/MnO<sub>2</sub>/PPC, NiO/MnO<sub>2</sub>/BHC, and NiO/MnO<sub>2</sub>/AC) are assembled. The results demonstrated that NiO/MnO<sub>2</sub>/BHC delivered substantial energy density (20.37 W h kg<sup>−1</sup> at a power density of 133.3 W kg<sup>−1</sup>), and excellent cycling stability (88% capacitance retention after 5000 cycles).

## 2. Experimental

### 2.1 Preparation of NiO/MnO<sub>2</sub> core–shell composites

The NiO/MnO<sub>2</sub> nanocomposite was prepared in two steps. First of all, the hollow NiO nanospheres were synthesized by a facile hydrothermal route.<sup>26–28</sup> In a typical process, 2.0 g of Na<sub>2</sub>SO<sub>4</sub> salt, 2.0 g of glycine, and 5.0 mmol of Ni(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O were dissolved in 25 mL of deionized water. 10 mL of a NaOH solution was gradually dropped into the above solution by syringe pump. The solution was then shifted to a 40 mL Teflon-lined autoclave and kept at 170 °C for 24 hours. Under ultrasonication, the samples were washed with deionized water several times and then dried at 60 °C. After that, the precursors were converted to NiO hollow spheres by calcining at 400 °C for 2 hours. Then the growth of the MnO<sub>2</sub> shell was studied using the NiO hollow spheres as the skeleton.

Fig. 1 XRD pattern of the NiO/MnO<sub>2</sub> core–shell nanocomposite.

Secondly, 4.0 g of NiO hollow spheres were dissolved in 40 mL of 0.02 mol L<sup>−1</sup> potassium permanganate (KMnO<sub>4</sub>) under vigorous magnetic stirring, and then transferred into a 50 mL Teflon-lined autoclave and kept at 120 °C for 12 h. Under ultrasonication, the samples were washed several times with deionized water and then dried at 60 °C for 6 h. The final product was denoted as the NiO/MnO<sub>2</sub> core–shell composite.

### 2.2 Preparation of PPC and BHC

The pomelo peel was cut into small pieces and then dried to constant weight at 60 °C. Then, 5 g of pomelo peel was immersed in 0.1 M citric acid, then heated to 200 °C and maintained for 6 h in a 100 mL Teflon-lined stainless steel autoclave.

After washing and drying, the sample was soaked in 4 M KOH solution for 12 h. After filtration and drying, the sample was heated to 350 °C (heating rate: 5 °C per minute) and held at that temperature for 0.5 h, heated up to 550 °C (heating rate: 5 °C per minute) and held for 0.5 h, and heated up to

Scheme 1 Preparation process for the asymmetric supercapacitor device based on a core–shell NiO/MnO<sub>2</sub> cathode and biochar anode.

Fig. 2 Nitrogen adsorption–desorption isotherm of hollow NiO spheres (a). Nitrogen adsorption–desorption isotherm of the NiO/MnO<sub>2</sub> core–shell nanocomposite (b).

700 °C (heating rate: 5 °C per minute) and held for 2 h under N<sub>2</sub> flow in a tubular oven. Finally, the activated samples were dipped in 1 M HCl solution and then washed with deionized water several times. The obtained sample was marked as PPC.

Using the same synthesis method, BHC was obtained.

AC was provided by Changchun Industrial Activated Carbon Co. Ltd.

### 2.3 Material characterization

The phase composition and crystal structure of the electrode materials were characterized by powder X-ray diffraction (XRD), which was conducted on a Rigaku D/max-IIIB diffractometer with the following test conditions: Cu K $\alpha$  as the X-ray source, wavelength of 0.15405 nm, and scanning speed of 10° min<sup>-1</sup>.

Scanning electron microscopy (SEM) was carried out using a Hitachi S-4800 with the following test conditions: working voltage of 10 kV and work distance of 12 mm. Transmission electron microscopy (TEM) was carried out using an FEI Tecnai G2 S-Twin. Nitrogen adsorption–desorption measurements (BET method) were performed at liquid nitrogen temperature with an ASAP 2010 apparatus from Micromeritics.

### 2.4 Electrochemical tests

The working electrodes were fabricated by mixing 10 mg of the NiO/MnO<sub>2</sub> core–shell composite with 1.33 mg of acetylene black, 1.33 mg of graphite and two drops of polytetrafluoroethylene (PTFE). A drop of ethanol was added to the above mixture to form a homogeneous paste with the assistance of

Fig. 3 (a) SEM image of the as-prepared precursor Ni(OH)<sub>2</sub>. (b) Magnified SEM image of the as-prepared precursor Ni(OH)<sub>2</sub>. (c) SEM image of NiO after being annealed at 400 °C. (d) SEM image of the NiO/MnO<sub>2</sub> core–shell composite.

ultrasonication. The above homogeneous paste was then coated on a nickel foam substrate ( $1 \times 1$  cm).

A three-electrode electrochemical cell was used to investigate the electrochemical properties of the as-obtained samples. The as-prepared  $\text{NiO}/\text{MnO}_2$  composite was used as the working electrode, a saturated calomel electrode (SCE) was used as the reference electrode and platinum foil ( $1 \times 1$  cm) was used as the counter electrode. 6.0 M KOH aqueous solution was used as the electrolyte. Cyclic voltammograms, galvanostatic charge/discharge curves, and electrochemical impedance spectroscopy (EIS) were employed to inspect the electrochemical performance of the  $\text{NiO}/\text{MnO}_2$  core–shell composite using a CHI 660D electrochemical workstation. Cyclic voltammetry (CV) curves were conducted at scan rates of 3, 5, and 10  $\text{mV s}^{-1}$  and the voltage range was from 0 to 0.5 V (vs. SCE). Galvanostatic charge/discharge tests were carried out at different current densities (5, 10, and 20  $\text{mA cm}^{-2}$ ) in the voltage range from 0 to 0.5 V (vs. SCE). EIS measurements were also taken in the frequency range from 100 kHz to 0.005 Hz.

The preparation process used for the working electrodes of the two kinds of biomass carbon (PPC and BHC) is the same as that for the  $\text{NiO}/\text{MnO}_2$  core–shell composite.

Three asymmetric supercapacitors ( $\text{NiO}/\text{MnO}_2/\text{PPC}$ ,  $\text{NiO}/\text{MnO}_2/\text{BHC}$ , and  $\text{NiO}/\text{MnO}_2/\text{AC}$ ) were assembled. According to charge balance theory,<sup>29</sup> the mass ratios of the positive and negative electrodes of  $\text{NiO}/\text{MnO}_2/\text{PPC}$ ,  $\text{NiO}/\text{MnO}_2/\text{BHC}$ , and  $\text{NiO}/\text{MnO}_2/\text{AC}$  were fixed at 1 : 3, 1 : 2, and 1 : 4, respectively.

### 3. Results and discussion

Fig. 1 shows the XRD pattern of the  $\text{NiO}/\text{MnO}_2$  core–shell composite. The cubic  $\text{MnO}_2$  phase (JCPDS: 44-0992) diffraction peaks and the cubic  $\text{NiO}$  phase (JCPDS: 47-1049) diffraction peaks<sup>30</sup> indicate that the  $\text{NiO}/\text{MnO}_2$  composite has been formed.

Fig. 2 presents the nitrogen adsorption–desorption isotherm of the  $\text{NiO}$  hollow spheres and the  $\text{NiO}/\text{MnO}_2$  core–shell composite. Both of the materials display type IV isotherms, which are representative of mesoporous materials according to the IUPAC classification. The surface areas of the  $\text{NiO}$  hollow spheres and the  $\text{NiO}/\text{MnO}_2$  core–shell composite calculated using a multipoint BET model are  $63 \text{ m}^2 \text{ g}^{-1}$  and  $89 \text{ m}^2 \text{ g}^{-1}$ , respectively.

The SEM image of the  $\text{Ni(OH)}_2$  sample (Fig. 3(a)) indicates that the particle size, ranging from 3 to 5  $\mu\text{m}$  in diameter, is uniform. A hollow structure can be observed at higher magnification (Fig. 3(b)), and the sample is composed of many  $\text{NiO}$  nanosheets, which facilitate rapid ion/electron transport. After being calcined at 400 °C (Fig. 3(c)), the diameter was reduced by 2–4  $\mu\text{m}$ , and the spheres still have a hollow structure. However, because the wall of the spheres is too thick, the hollow structure cannot be found in the TEM image (Fig. 4(a)), but the image shows that the surface of the hollow  $\text{NiO}$  spheres is smooth. For the  $\text{NiO}/\text{MnO}_2$  core–shell composite (Fig. 3(d)), the  $\text{MnO}_2$  nanosheet shells can be seen on the hollow  $\text{NiO}$  sphere cores, and the  $\text{MnO}_2$  nanosheets are interlinked with lengths up to 100 nm. This structure makes the composite more closely

Fig. 4 (a) TEM image of  $\text{NiO}$  after being annealed at 400 °C. (b) TEM image of the  $\text{NiO}/\text{MnO}_2$  core–shell composite. (c) HRTEM image of the  $\text{NiO}/\text{MnO}_2$  core–shell composite.

arranged and the small gaps in the composite can provide channels for electrolyte insertion and extraction. Finally, full use can be made of the effective area of the active material. The TEM image (Fig. 4(b)) further confirms that thin  $\text{MnO}_2$  nanosheets uniformly grew on the surface of the hollow  $\text{NiO}$  spheres. HRTEM (Fig. 4(c)) was performed to further elucidate the surface plane of the  $\text{NiO}/\text{MnO}_2$  core–shell composite. In Fig. 4(c), the lattice fringes can be observed. However, the lattice structure of  $\text{MnO}_2$  ( $d_{(120)} = 0.28 \text{ nm}$ ) is not obvious, which may be caused by its poor crystal shape, which is consistent with the XRD results. The lattice fringe corresponding to the (200) ( $d = 0.20 \text{ nm}$ ) crystallographic plane of  $\text{NiO}$  is shown.

Fig. 5 exhibits EDS images of the  $\text{NiO}/\text{MnO}_2$  core–shell composite. O, Ni, Mn and K elements are observed. K element is from the raw material  $\text{KMnO}_4$ . The mass percentages of O, Ni and Mn are 30.7%, 14.20% and 20.31%, respectively. Fig. 5(d)–(f) present the EDS mapping for the  $\text{NiO}/\text{MnO}_2$  core–shell composite, showing the distribution of elements Ni, Mn, and O.

Fig. 6(A) shows the CV curves of the  $\text{NiO}/\text{MnO}_2$  core–shell composite at different scan rates ranging from 5 to 20  $\text{mV s}^{-1}$ . All the CV curves have similar shapes, and these shapes indicate that the capacitance characteristic is different from that of traditional electric double-layer capacitance. As the scan rate

increases, the current increases subsequently. This indicates that  $\text{NiO}/\text{MnO}_2$  core–shell composite has fast electron and ion diffusion rates. The specific capacitance of the electrode can be obtained from the following equation:<sup>31</sup>

$$C = \frac{1}{mv(V_a - V_c)} \int_{V_a}^{V_c} |i| dV \quad (1)$$

where  $C$  is the specific capacitance of the electrode ( $\text{F g}^{-1}$ ),  $v$  is the scan rate ( $\text{V s}^{-1}$ ),  $i$  is the current density ( $\text{A cm}^{-2}$ ),  $m$  is the mass of the active electrode materials (g),  $V_c$  is the final voltage (V), and  $V_a$  is the initial voltage (V). The specific capacitances of the  $\text{NiO}/\text{MnO}_2$  core–shell composite at 5, 10 and 20  $\text{mV s}^{-1}$  were calculated to be 552  $\text{F g}^{-1}$ , 452  $\text{F g}^{-1}$  and 320  $\text{F g}^{-1}$ , respectively. This implies that with the increase of sweep rate, only a few  $\text{OH}^-$  can achieve electrode materials, which means that the active material can not be made full use, and the specific capacitance is reduced. Fig. 6(B) presents the CV curves of the  $\text{NiO}/\text{MnO}_2$  core–shell composite and the hollow  $\text{NiO}$  spheres at the scan rates of 5  $\text{mV s}^{-1}$ . It can be seen that the enclosed area of the CV loop of the hollow  $\text{NiO}$  spheres is smaller than that of the  $\text{NiO}/\text{MnO}_2$  core–shell composite. According to eqn (1), the specific capacitance of the  $\text{NiO}/\text{MnO}_2$  core–shell composite is 552  $\text{F g}^{-1}$ . This indicates that the  $\text{NiO}/\text{MnO}_2$  core–shell

Table 1 Comparison of electrode properties with reported literature

Sample	Specific capacitance	Working potential	Electrolyte	Energy density, power density	Supp. ref.
NiO@MnO <sub>2</sub> core–shell structure	766.8 F g <sup>-1</sup> (10 A g <sup>-1</sup> )	0–0.5 V vs. SCE	2.0 M KOH	—	35
NiO@MnO <sub>2</sub> core–shell nanocomposite	266.7 F g <sup>-1</sup> (0.5 A g <sup>-1</sup> )	0–0.45 V vs. SCE	2.0 M KOH	—	36
NiO/MnO <sub>2</sub> core–shell nanoflakes	241 mF cm <sup>-2</sup> (1 mA cm <sup>-2</sup> )	0–0.7 V vs. SCE	1.0 M KOH	—	37
NiO/MnO <sub>2</sub> core–shell composite	528 F g <sup>-1</sup> (1 mV s <sup>-1</sup> )	0–0.5 V vs. Ag/AgCl	1 M LiOH	—	30
NiO/MnO <sub>2</sub> core–shell composite	558 F g <sup>-1</sup> (5 mA cm <sup>-2</sup> )	0–0.5 V vs. SCE	6.0 M KOH	20.37 W h kg <sup>-1</sup> , 133.3 W kg <sup>-1</sup>	This work

composite has low internal resistance and that electron/ion transport is fast. Fig. 6(C) shows the galvanostatic charge/discharge curves of the NiO/MnO<sub>2</sub> core–shell composite at different current densities, and the specific capacitance can be calculated from the following equation:<sup>32</sup>

$$C_m = \frac{I \times \Delta t}{\Delta V \times m} \quad (2)$$

where  $C_m$  is the specific capacitance of the electrode (F g<sup>-1</sup>),  $\Delta V$  is the potential drop during discharge,  $\Delta t$  is the discharge time (s),  $m$  is the mass of the active electrode materials, and  $I$  is the charge/discharge current (A). At current densities of 5, 10 and 20 mA cm<sup>-2</sup>, the specific capacitance of the NiO/MnO<sub>2</sub> core–shell composite electrode was calculated to be about 558, 466 and 388 F g<sup>-1</sup>, respectively. The results indicate that the smaller the current density, the slower the rate of movement of OH<sup>-</sup> ions, enabling good contact between the active material and the ions. Fig. 6(D) shows the galvanostatic charge/discharge curve of the NiO/MnO<sub>2</sub> core–shell composite at a current density of 5 mA

cm<sup>-2</sup> and the galvanostatic charge/discharge curve of the hollow NiO spheres at a current density of 5 mA cm<sup>-2</sup>. Significantly, at the current density of 5 mA cm<sup>-2</sup>, the galvanostatic charge/discharge curve of the hollow NiO exhibits a much shorter discharge time compared to that of the NiO/MnO<sub>2</sub> core–shell composite and the specific capacitance of the NiO/MnO<sub>2</sub> core–shell composite is calculated to be about 558 F g<sup>-1</sup>. The results indicate that MnO<sub>2</sub> nanosheets grown on the surface of the hollow NiO greatly improved the active area. Furthermore, MnO<sub>2</sub> nanosheets are not a closed structure, and there is plenty of space for electrolyte ion penetration. Therefore, the core–shell structure not only provides a greater active surface area but also greatly reduces the OH<sup>-</sup> insertion and extrusion pathways. Compared to previous reports, the NiO/MnO<sub>2</sub> core–shell composite in our work is much superior to those of other core–shell architectures, as shown in Table 1. Such outstanding high electrochemical performance further proves the great advantages of the present core–shell heterostructured composite. Fig. 6(E) shows the cyclic performance of the NiO/MnO<sub>2</sub> core–

Fig. 7 SEM image of PPC (A). SEM image of BHC (B). CV curves of PPC, BHC and AC at the scan rates of 5 mV s<sup>-1</sup>, in 6.0 M KOH solution (C). Galvanostatic charge/discharge curves of PPC, BHC and AC at the current density of 5 mA cm<sup>-2</sup>, in 6.0 M KOH solution (D).

shell composite at the 1st and 5000th cycles at a scan rate of  $5 \text{ mV s}^{-1}$ . As one can see, the curves have a high degree of overlap and this shows that the sample has good cyclic stability. Fig. 6(F) shows the cycling performance of the  $\text{NiO}/\text{MnO}_2$  core–shell composite at a constant current of  $10 \text{ mA cm}^{-2}$ . It can be seen that after 5000 cycles the capacitance decreases by 17%, demonstrating the excellent cyclic stability and long cycle lifetime of the  $\text{NiO}/\text{MnO}_2$  core–shell composite. Fig. 6(G) shows the EIS of the hollow  $\text{NiO}$  spheres and the  $\text{NiO}/\text{MnO}_2$  core–shell composite, and the equivalent circuit diagram is presented in Fig. 6(H), where  $R_{ct}$  is the Faradaic interfacial charge transfer resistance,  $C_d$  is a double-layer capacitor,  $R_s$  is the solution resistance of the electrochemical system,  $W$  is the Warburg impedance, and  $C_F$  is a faradaic pseudocapacitor.<sup>33</sup> It can be

seen from Fig. 6(G) that in the high frequency region, the two samples have different solution resistance,  $R_s$ ; the  $R_s$  of the hollow  $\text{NiO}$  spheres is  $1.9 \Omega$  and the  $R_s$  of the  $\text{NiO}/\text{MnO}_2$  core–shell composite is  $0.5 \Omega$ . From the diameters of the semicircles, the charge transfer resistance,  $R_{ct}$ , of the hollow  $\text{NiO}$  spheres and the  $\text{NiO}/\text{MnO}_2$  core–shell composite can be estimated to be  $4 \Omega$  and  $0.5 \Omega$ , respectively. The results indicate that the  $\text{NiO}/\text{MnO}_2$  electrode has a higher specific surface area and more active material, which makes it easier to reach the active site, shortens the ion transport path, and reduces charge transfer resistance. For the hollow  $\text{NiO}$  sphere electrode, the increase in charge transfer resistance is attributed to the decreased amount of active material.<sup>34</sup>

**Fig. 8** CV curves of the different supercapacitors at a scan rate of  $5 \text{ mV s}^{-1}$  in  $6.0 \text{ M KOH}$  solution (A). Galvanostatic charge/discharge curves of the different supercapacitors at a current density of  $5 \text{ mA cm}^{-2}$  in  $6.0 \text{ M KOH}$  solution (B). Electrochemical impedance spectra (EIS) of the different supercapacitors (C). Specific capacitances of the different supercapacitors at different current densities (D). Ragone curves of the different supercapacitors (E). Cycling performance of the different supercapacitors at a constant current of  $5 \text{ mA cm}^{-2}$  (F).

In order to further determine the morphologies and properties of different biochar, the SEM images and electrochemical properties are shown in Fig. 7. It can be seen that there are a large number of pores in the PPC (Fig. 7(A)) and BHC (Fig. 7(B)). However, the channels in the BHC are connected, while the channels in PPC are closed. The rapid diffusion of electrolyte ions and the fast transfer of electrons are attributed to this highly connected structure. CV curves of the different samples (PPC, BHC and AC) are shown in Fig. 7(C). A nearly rectangular shaped loop can be observed, which indicates that the materials have typical and ideal capacitive behaviors.<sup>22</sup> As is known, the capacitance of the electrode material is directly proportional to the area it encloses, so according to eqn (1), BHC has the highest specific capacitance. The galvanostatic charge/discharge curves of the different samples (BHC, PPC and AC) are presented in Fig. 7(D). According to eqn (2), the specific capacitances of BHC, PPC and AC can be calculated to be 176.1 F g<sup>-1</sup>, 105.4 F g<sup>-1</sup> and 83 F g<sup>-1</sup>, respectively. The results are in agreement with Fig. 7(C).

To further evaluate the electrochemical performance of the NiO/MnO<sub>2</sub> core-shell composite electrode, a series of asymmetric supercapacitor devices using the NiO/MnO<sub>2</sub> core-shell composite electrode as the cathode and biochar as the anode are assembled. The CV curves of the different supercapacitors are shown in Fig. 8(A). According to eqn (1), NiO/MnO<sub>2</sub>//BHC has the highest current response and the largest integral area according to its highest specific capacitance. Galvanostatic charge/discharge curves of NiO/MnO<sub>2</sub>//PPC, NiO/MnO<sub>2</sub>//BHC, and NiO/MnO<sub>2</sub>//AC are exhibited in Fig. 8(B). According to eqn (2) (where *m* is the total weight of the negative and positive electrode materials), the specific capacitances of NiO/MnO<sub>2</sub>//BHC, NiO/MnO<sub>2</sub>//PPC, and NiO/MnO<sub>2</sub>//AC can be calculated to be 57.3 F g<sup>-1</sup>, 33.3 F g<sup>-1</sup> and 26.5 F g<sup>-1</sup>, respectively. The results indicate that the electrode material of NiO/MnO<sub>2</sub>//BHC not only provides a large surface area for charge storage but also promotes efficient electrolyte/electrode contact and the specific capacitance is improved. The EIS of the different supercapacitors are demonstrated in Fig. 8(C). It can be seen that the three supercapacitors have different solution resistances (*R*<sub>s</sub>, *x*-intercept), and the *R*<sub>s</sub> of NiO/MnO<sub>2</sub>//BHC, NiO/MnO<sub>2</sub>//PPC and NiO/MnO<sub>2</sub>//AC are 2.8 Ω, 2.78 Ω and 3.0 Ω, respectively. Furthermore, the charge transfer resistances (*R*<sub>ct</sub>, the diameter of the semicircles) of NiO/MnO<sub>2</sub>//BHC, NiO/MnO<sub>2</sub>//PPC and NiO/MnO<sub>2</sub>//AC can be calculated to be 0.7 Ω, 1.3 Ω and 1.1 Ω, respectively. The specific capacitances of the different supercapacitors at different current densities are shown in Fig. 8(D). It can be seen that NiO/MnO<sub>2</sub>//BHC has the highest rate capability and the highest specific capacitance. In order to further evaluate the electrochemical properties, Ragone curves (Fig. 8(E)) are demonstrated. According to eqn (3) and (4),<sup>38,39</sup> the power density of NiO/MnO<sub>2</sub>//BHC is calculated to be 133.3 W kg<sup>-1</sup> and the energy density is 20.37 W h kg<sup>-1</sup>. Furthermore, the energy density can still remain 13.55 W h kg<sup>-1</sup> at a high power density of 810.33 W kg<sup>-1</sup>.

$$E = \frac{C \times V^2}{2 \times 3.6} \quad (3)$$

$$P = \frac{E \times 3600}{t} \quad (4)$$

The cycling performance of the different supercapacitors is exhibited in Fig. 8(F). After 5000 cycles, the specific capacitances of NiO/MnO<sub>2</sub>//BHC, NiO/MnO<sub>2</sub>//PPC and NiO/MnO<sub>2</sub>//AC remained at 88%, 81% and 77% of their maximums, which shows that NiO/MnO<sub>2</sub>//BHC possesses excellent cycling stability and a long cycle life.

## 4. Conclusions

Hierarchical MnO<sub>2</sub> nanosheets attached on hollow NiO microspheres have been fabricated by a facile hydrothermal method. The core-shell structure is achieved by decorating MnO<sub>2</sub> nanosheets on NiO hollow spheres. Batch experiments were conducted to examine the electrochemical properties. The results indicated that the NiO/MnO<sub>2</sub> composite exhibits outstanding electrochemical properties (558 F g<sup>-1</sup> at a current density of 5 mA cm<sup>-2</sup>) and excellent cycling stability (83% capacitance retention after 5000 cycles). For comparison, three asymmetric supercapacitors (NiO/MnO<sub>2</sub>//pomelo peel (PPC), NiO/MnO<sub>2</sub>//buckwheat hull (BHC), and NiO/MnO<sub>2</sub>//AC) were assembled. The results demonstrated that NiO/MnO<sub>2</sub>//BHC delivered substantial energy density (20.37 W h kg<sup>-1</sup> at a power density of 133.3 W kg<sup>-1</sup>) and high long-term stability (88% capacitance retention after 5000 cycles) within a broad operating potential window of 1.6 V.
