Supply of methionine and arginine alters phosphorylation of mechanistic target of rapamycin (mTOR), circadian clock proteins, and α -s1-casein abundance in bovine mammary epithelial cells†

Liangyu Hu,^{a,b} Yifei Chen,^a Ismael M. Cortes,^c Danielle N. Coleman,^b Hongyu Dai,^{b,d} Yusheng Liang,^b Claudia Parys,^e Carlos Fernandez,^f Mengzhi Wang^{*a} and Juan J. Llor^{id} ^{*b}

Methionine (Met) and arginine (Arg) regulate casein protein abundance through alterations in activity of the mechanistic target of rapamycin complex 1 (mTORC1) signaling pathway. A potential role for the circadian clock network on the regulation of protein synthesis, partly *via* activity of mTORC1, has been highlighted in non-ruminants. The main objective of the study was to determine in ruminant mammary cells alterations in mRNA, protein abundance and phosphorylation status of mTORC1-related upstream targets, circadian clock proteins, and protein kinase AMP-activated catalytic subunit alpha (AMPK) in relation to α -s1-casein protein (CSN1S1) abundance in response to greater supply of Met and Arg alone or in combination. Primary bovine mammary epithelial cells (BMEC) were incubated for 12 h in a 2 × 2 arrangement of treatments with control media (ideal profile of amino acids, IPAA), or media supplemented with increased Met (incMet), Arg (incArg), or both (incMet + incArg). Data were analyzed testing the main effects of Met and Arg and their interaction. Among 7 amino acid (AA) transporters known to be mTORC1 targets, increasing supply of Arg downregulated *SLC1A5*, *SLC3A2*, *SLC7A1*, and *SLC7A5*, while increasing supply of Met upregulated *SLC7A1*. mRNA abundance of the cytosolic Arg sensor (*CASTOR1*) was lower when supply of Arg and Met alone increased. p-TSC2 (TSC complex subunit 2) was greater when the Arg supply was increased, while the phosphorylation ratio of p-AKT (AKT serine/threonine kinase 1):total (t) AKT and p-AMPK:tAMPK were lower. In spite of this, the ratio of p-mTOR:tmTOR nearly doubled with incArg but such response did not prevent a decrease in CSN1S1 abundance. The abundance of period circadian regulator 1 (PER1) protein nearly doubled with all treatments, but only incMet + incArg led to greater clock circadian regulator (CLOCK) protein abundance. Overall, data suggest that a greater supply of Met and Arg could influence CSN1S1 synthesis of BMEC through changes in the mTORC1, circadian clock, and AMPK pathways. Identifying mechanistic relationships between intracellular energy, total AA supply, and these pathways in the context of milk protein synthesis in ruminants merits further research.

Introduction

Amino acids (AA) can be used by the mammary gland as substrates to synthesize milk protein¹ and as signaling factors to regulate casein protein gene transcription and translation through pathways^{2–4} such as the mechanistic target of rapamycin complex 1 (mTORC1). Methionine (Met) is identified frequently in dairy cows as the most-limiting AA for milk and milk protein synthesis,^{5,6} especially on highly corn-based diets.⁷ Arginine (Arg) belongs to the conditionally-essential amino acids (EAA)⁸ that indirectly could affect milk protein synthesis.⁹

Providing a well-balanced supply of EAA can serve as an opportunity to increase the efficiency of metabolizable protein (MP) utilization for milk protein yield.¹⁰ Rulquin *et al.* (2007)¹¹ proposed an ideal profile for intestinally-absorbed EAA in the form of percentage of MP in which a 7.3% Lys to 2.5% Met was deemed optimal. This relationship was subsequently tested by Haque *et al.* (2012)¹⁰ where balancing the EAA profiles was independent of MP supply levels. Nan *et al.* (2014)¹² working with mammary cells provided data suggesting that a ratio of Lys:Met at about 2.9:1 was optimum for enhancing casein concentration *in vitro*, partly *via* alterations in mRNA and protein abundance of mTORC1 targets. In the case of Arg, published recommendations range from 3.1%¹³ to 4.8%¹⁴ of MP, and Haque *et al.* (2013)¹⁵ subsequently concluded that compared with highest levels proposed a supply of 3.5% Arg of MP (Lys:Arg at 2:1) was not limiting for milk protein synthesis.

Recent *in vitro* studies reported a positive effect of greater Arg supply (Lys:Arg at 1:1) on mRNA and protein abundance of various components of the milk protein synthesis network,¹⁶ but a negative impact of supplying Met beyond the 3:1 ratio of Lys:Met.¹⁷ Although most published studies have focused on the optimal supply of Met and Arg with respect to the role of mTORC1 downstream factors on milk protein synthesis, recent research has identified important roles of factors upstream of mTORC1,^{18,19} AA transporters²⁰ and AA sensors^{21,22} in the overall regulation of protein synthesis. Thus, detailed mechanisms encompassing not only mTORC1 in response to changes in AA supply merit further research.

The circadian clock, a mammalian internal timing system present in all organs,²³ orchestrates temporal physiology to optimize the timing of metabolic processes.^{24–26} mTORC1 is capable of coupling environmental inputs, including AA availability, to the circadian clock and its signaling network. Data from a recent review of the non-ruminant literature underscored a reciprocal interplay between circadian clock and mTORC1 signaling,²⁷ with a key premise being that mTORC1 activity is regulated by the circadian clock. In turn, the rhythmicity of mTORC1 and its downstream signaling components impact autonomous properties as well as core clock proteins both in suprachiasmatic nucleus (SCN) and some peripheral tissues (*e.g.* liver).²⁸ Although not known, bidirectional regulation between circadian clock and mTORC1 may also be part of the mechanisms controlling milk protein synthesis in mammary gland. Thus, as underscored by the recognition that there are annual rhythms in milk yield and milk components,²⁹ adding this dimension to research of mechanisms controlling milk protein synthesis is needed for an integrated understanding of mammary cell physiology.

In this study, we hypothesized that a greater supply of Met or Arg based on an ideal AA profile which has been used in cell culture studies from our laboratory^{17,30,31} stimulates casein protein abundance in bovine mammary epithelial cells (BMEC). We used mRNA and protein abundance analyses to explore the potential molecular mechanisms involved in the coordination of upstream components of mTORC1 signaling and the circadian clock network.

Materials and methods

Cell culture

The cell culture was performed using primary BMEC (kindly provided by Prof. Mengzhi Wang, Yangzhou University). The BMEC cells were allowed to grow in cell dishes (BioLite 100 mm, #130182, Thermo Scientific, Rochester, NY) at 37 °C and 5% CO₂ to generate enough biological material, and were then transferred into 6-well plates (1.2 × 10⁵ cells per well, #140675, Thermo Scientific, Waltham, MA) with basal media composed of high-glucose Dulbecco's modified Eagle's media (1, #11995, Gibco, Carlsbad, CA), 10% fetal bovine serum (#16140, Gibco, Invitrogen, Carlsbad, CA) and 1× penicillin/streptomycin (#sv30010, HyClone, South Logan, UT). Cells grew to approximately 90% confluence before imposing treatments as described previously.³²

Treatments and experimental design

The BMEC in 6-well plates (about 90% confluence) were serum-starved overnight and then incubated (*n* = 5 replicates per treatment) for 12 h with 4 modified lactogenic media as follows: media with ideal profile of AA^{10,15} as the control (IPAA; Lys:Met 2.9:1, Lys:Arg 2:1), and treatment media was supplemented with increased Met (incMet, Lys:Met 2.5:1), Arg (incArg, Lys:Arg 1:1), or both (incMet + incArg; Lys:Met 2.5:1, Lys:Arg 1:1) based on the IPAA.

The modified lactogenic media was prepared according to Dong *et al.* (2018).^{17,33} The 10 EAA (L-isomer, Sigma-Aldrich, St Louis, MO) were individually added into the custom high-glucose DMEM (devoid of these 10 EAA, custom made from Gibco, Carlsbad, CA). Treatment media were prepared by increasing only Met, Arg or both while keeping the concentrations of 7 other EAA (histidine, isoleucine, leucine, phenylalanine, threonine, tryptophan, valine) the same across all media (Table 1).

RNA extraction and quantitative RT-PCR analysis

After 12 h of incubations with treatments, BMEC were scraped using a cell lifter in 1 mL of QIAzol reagent (#79306, Qiagen, Valencia, CA) and total RNA was obtained using the RNeasy Mini kits (#74104, Qiagen, Valencia, CA). The RNA concentration and integrity were determined by ND-1000 spectrophotometer (Nano-Drop Technologies, Wilmington, DE) and Agilent 2100 Bioanalyzer (Agilent Technologies, Santa Clara, CA). Samples for subsequent analysis had an RNA Integrity Number (RIN) ≥8.0, and 100 ng of RNA was used for cDNA synthesis.

Quantitative real-time polymerase chain reaction (qRT-PCR) was performed as described previously. The list of target genes is reported in ESI Table 1.† Briefly, 4 µL diluted cDNA was combined with 6 µL of a mixture composed of 5 µL 1× SYBR Green Master Mix (Quanta, Gaithersburg, MD), 0.4 µL each of 10 µM forward and reverse primers, and 0.2 µL RNase free water. Reaction mixtures were preheated at 95 °C for 5 min, followed by 40 cycles of melting at 95 °C for 15 s, and annealing at 60 °C for 30 s. The standard curve method and

Table 1 Amino acid (AA) composition^a of the ideal AA profile (IPAA; Lys:Met 2.9:1, Lys:Arg 2:1) and treatments supplemented with increased Arg (incArg), Met (incMet), or both (incMet + incArg)

^aThe AA were individually added into the custom high-glucose Dulbecco's modified Eagle's media (DMEM) devoid of these 10 EAA. Concentrations of other AA in the custom high-glucose DMEM are glycine = $30 \mu\text{g mL}^{-1}$, L-cystine = $63 \mu\text{g mL}^{-1}$, L-glutamine = $584 \mu\text{g mL}^{-1}$, L-serine = $42 \mu\text{g mL}^{-1}$, and L-tyrosine = $104 \mu\text{g mL}^{-1}$. ^bIPAA = ideal profile of AA, Lys:Met 2.9:1, Lys:Arg 2:1; incArg = increased supply of Arg, Lys:Met 2.9:1, Lys:Arg 1:1; incMet = increased supply of Met, Lys:Met 2.5:1, Lys:Arg 2:1; incMet + incArg = increased supply both of Met and Arg, Lys:Met 2.5:1, Lys:Arg 1:1. Concentrations and ratios of other 7 AA were the same in all groups.

QuantStudio™ 7 Flex Real-Time PCR Software (Applied Biosystems, CA) were used for data analysis. The internal controls used for normalization of target gene abundance were glyceraldehyde-3-phosphate dehydrogenase (*GADPH*), ubiquitously expressed prefoldin like chaperone (*UXT*), and ribosomal protein S9 (*RPS9*). The expression of the internal control genes was not affected by treatment ($P > 0.10$). Normalization of the target gene abundance was performed by dividing their relative abundance by the geometric mean of the three internal control genes. Primers (ESI Table 1†) were designed and verified based on established protocols in our laboratory.³⁴ qRT-PCR performance was reported in ESI Table 2.†

Western blotting

Complete details of these protocols are reported in our previous publications. Briefly, the BMEC were washed three times with phosphate-buffered saline, and total protein collected using ice-cold M-PER mammalian protein extraction reagent (#78501, Thermo Scientific, Waltham, MA) containing 1% halt protease and phosphatase inhibitor cocktail (#78440, Thermo Scientific). Lysates were centrifuged at $14\,000g$ for 10 min at 4°C , and then the supernatants harvested for measuring and normalizing protein concentration with the BCA protein assay kit (#23227, Thermo Scientific). Proteins (20 μL of total protein) and 4× Laemmli sample buffer (#161-0747, Bio-Rad, Hercules, CA) were mixed at a ratio of 3:1 (wt:vol) and denatured at 95°C for 10 min. Samples were subjected to 10% SDS/PAGE and then transferred to a PVDF membrane (#1620261, Bio-Rad) by using Trans-Blot SD Semi-Dry

Electrophoretic Transfer Cell (#170-3940, Bio-Rad) for 25 min, and PVDF membranes were incubated with primary antibody (listed in ESI Table 3†) overnight at 4°C after blocking for 2 h with 5% skim milk (#1706404XTU, Bio-Rad) for total proteins or 5% bovine serum albumin (#A7960, sigma, St Louis, MO) for phosphorylated proteins and casein at room temperature. The PVDF membranes were then washed 6 times (5 min per time) and incubated with secondary antibody for 1.5 h at room temperature before washing again. The visualization of PVDF membranes was performed using the ChemiDoc MP System (Bio-Rad) with Clarity Western ECL Substrate (#170-5060, Bio-Rad) reagent. Band intensities were quantified using Image Lab software (version 3.0, Bio-Rad), and phosphorylation state was calculated as the intensity ratio of phosphorylated protein to total protein (arbitrary units). The intensity of GAPDH was used to normalize target protein abundance.

Statistical analysis

All data were analyzed as a 2×2 factorial arrangement of treatments using the MIXED procedure of SAS 9.4 (SAS Institute Inc., Cary, NC). The main factors were Met and Arg, with each containing 2 levels: “yes” the AA was greater or “no” it was the same as IPAA. The model tested the effects of Met, Arg and the interaction between them. Least square means and standard errors were determined using the LSMEANS statement and means were compared using Tukey's when a significant interaction between Met and Arg was observed. Variables were assessed for normality of distribution using the Shapiro-Wilk test. mRNA abundance data were \log_2 -scale transformed to fit normal distribution of residuals. The tables contain the \log_2 back-transformed means that resulted from analysis. Significance was declared at $P \leq 0.05$ and tendencies as $P \leq 0.10$.

Results

mRNA abundance

AA transporters. No significant interaction between increased supply of Met and Arg was observed for all AA transporters ($P > 0.10$). Abundance of solute carrier family 7 member 1 (*SLC7A1*, functions described in ESI Table 4†) was greater with increased Met supplementation ($P = 0.003$; Table 2) and lower with Arg supplementation ($P = 0.011$). There was also an overall effect of Arg on *SLC7A5*, *SLC3A2*, and *SLC1A5* ($P < 0.0001$) where mRNA abundance decreased when Arg supply was increased. The mRNA abundance of *SLC1A1*, *SLC38A2*, and *SLC38A9* was not significantly different ($P > 0.05$) with AA treatment.

AA sensors and upstream factors in the mTOR pathway. A tendency for a Met \times Arg interaction was observed for WD repeat domain 24 (*WDR24*, $P = 0.083$; Table 2) where treatment with incMet and incArg alone or in combination decreased mRNA abundance compared with IPAA ($P < 0.05$). Additionally, compared with incArg, culture with incMet and incMet + incArg led to lower abundance of *WDR24* ($P < 0.05$). No significant Met \times Arg interaction was observed for the other AA

Table 2 Effects of incubating primary bovine mammary cells with the ideal AA profile (IPAA; Lys : Met 2.9 : 1, Lys : Arg 2 : 1), and increased supply of Arg (incArg), Met (incMet), or both (incMet + incArg) on relative mRNA abundance (\log_2 -scale)^a of AA transporters, AA sensors, and components of AMPK–SIRT1 pathway

sensors and upstream factors in the mTOR pathway that were evaluated. Abundance of cytosolic arginine sensor for mTORC1 subunit 1 (*CASTOR1*) was lower with greater supply of Met ($P = 0.002$) and Arg ($P = 0.05$; Table 2). Incubation with increased supply of Arg led to lower mRNA abundance of meiosis regulator for oocyte development (*MIOS*, $P = 0.014$) and greater abundance of DEP domain containing 5 (*DEPDC5*, $P = 0.007$). For members of the Rag GTPases, increased supply of Met resulted in lower mRNA abundance of Ras related GTP binding A (*RRAGA*, $P = 0.011$). Abundance of taste 1 receptor member 3 (*TAS1R3*) and phosphatidylinositol 3-kinase catalytic subunit type 3 (*PIK3C3*) did not differ statistically due to Arg, Met or their interaction ($P > 0.05$).

AMPK–SIRT1 pathway related genes. No significant interaction between Met and Arg was observed for the mRNA abun-

dance of genes related to the AMPK–SIRT1 pathway. There was an overall effect of Arg on sirtuin 1 (*SIRT1*, $P < 0.0001$) where mRNA abundance was decreased when Arg supply was increased (Table 2). Abundance of nicotinamide phosphoribosyltransferase (*NAMPT*) was lower in response to both increased supply of Met ($P = 0.046$) and Arg ($P < 0.0001$). No statistical difference was detected for serine/threonine kinase 11 (*STK11*) abundance in response to AA treatments ($P > 0.05$).

Protein abundance and phosphorylation status

Regulators of mTORC1. There were no statistical differences for the protein abundance of *CASTOR1*, *MIOS*, *NPR3* like, *GATOR1* complex subunit (*NPRL3*), *RRAGA*, or *PIK3C3* in response to Arg, Met or their interaction ($P > 0.05$; Table 3). Similarly, protein abundance of the AA sensor *TAS1R1* did not

differ statistically due to AA treatments ($P > 0.10$). Representative western blots are reported in ESI Fig. 1†

α -S1-casein and mTORC1 related pathways. An interaction ($P = 0.005$; Table 4) between Met and Arg was observed for the abundance of mTOR; compared with IPAA, incArg and incMet alone or in combination led to lower protein abundance of mTOR ($P < 0.05$). An interaction was also observed for the abundance of p-mTOR ($P = 0.04$) and p-AMPK (protein kinase AMP-activated catalytic subunit alpha) ($P = 0.006$) where incMet + incArg had lower p-mTOR abundance compared with incArg ($P = 0.04$), while incArg led to lower p-AMPK compared with IPAA ($P = 0.002$) and incMet ($P = 0.04$). In spite of this, there was a Met \times Arg interaction for the ratio of p-mTOR:total (t) mTOR ($P = 0.002$) which nearly doubled with incArg compared with IPAA ($P = 0.02$). However, such response did not prevent a decrease in α -s1-casein protein abundance (CSN1S1, interaction $P = 0.03$). There was also a tendency of Met \times Arg for p-TSC2 (TSC complex subunit 2):tTSC2 ($P = 0.064$); compared with IPAA, treatment with incArg ($P = 0.003$) and incMet + incArg ($P = 0.009$) led to greater p-TSC2:tTSC2. Additionally, the abundance of p-TSC2 ($P = 0.006$) was greater with increased supply of Arg.

An overall effect of Arg on p-AKT (AKT serine/threonine kinase 1) ($P = 0.02$), p-AKT:tAKT ($P = 0.049$), and p-AMPK:tAMPK ($P = 0.007$) was observed where abundance was decreased when Arg supply increased. No statistical difference ($P > 0.05$) was detected for total protein abundance of AKT, AMPK, TSC2, extracellular regulated protein kinase (ERK), as well as phosphorylation status of ERK. Representative western blots are reported in ESI Fig. 2.†

Circadian clock proteins. There was a Met \times Arg interaction for period circadian regulator 1 (PER1, $P = 0.008$; Table 5) and clock circadian regulator (CLOCK, $P < 0.0001$) where abundance of PER1 nearly doubled with increased Met and Arg alone or in combination compared with IPAA ($P < 0.05$), but only incMet + incArg led to greater CLOCK abundance than other treatments ($P < 0.01$). In addition, increased Met supply ($P = 0.049$) and increased Arg supply ($P = 0.004$) individually resulted in lower abundance of CLOCK. Abundance of period circadian regulator 2 (PER2) protein was lower in response to greater supply of Arg ($P = 0.016$). However, protein abundance of aryl hydrocarbon receptor nuclear translocator like (ARNTL, formerly BMAL1) and cryptochrome circadian regulator 1 (CRY1) did not differ statistically due to Arg, Met or their interaction ($P > 0.05$). Representative western blots are reported in ESI Fig. 3.†

Discussion

Without supplemental rumen-protected Met, the ratio of Lys : Met often ranges between 3.6 : 1 and 3.8 : 1 in corn silage-based diets.^{6,35} The currently-accepted IPAA ratio to maximize milk protein content and yield in established lactation is approximately 2.9:1 Lys:Met and is achieved by feeding rumen-protected Met.^{10–12,36} Increasing the post-ruminal supply of Met in dairy cows to levels in IPAA by feeding rumen-protected supplements has positive effects on production performance,⁶ milk protein content,^{37,38} and other physiological functions such as the immune response.^{39,40} As for Arg, com-

Table 5 Effects of incubating primary bovine mammary cells with the ideal AA profile (IPAA; Lys : Met 2.9 : 1, Lys : Arg 2 : 1), and increased supply of Arg (incArg), Met (incMet), or both (incMet + incArg) on relative abundance of circadian clock-related proteins^a

Protein	Treatment				SEM	P-Values		
	IPAA	incArg	incMet	incMet + incArg		Met	Arg	Met × Arg
CLOCK	0.15 ^b	0.10 ^c	0.11 ^c	0.22 ^a	0.02	0.001	0.059	<0.0001
ARNTL	0.79	0.74	0.70	0.67	0.12	0.481	0.703	0.922
CRY1	0.37	0.31	0.34	0.37	0.03	0.644	0.636	0.167
PER1	0.27 ^b	0.51 ^a	0.46 ^a	0.40 ^a	0.05	0.037	0.003	0.008
PER2	0.30	0.24	0.34	0.17	0.04	0.820	0.016	0.211

^{a-c}Means within a row with different superscripts differ (Met × Arg, $P < 0.05$). ^aThe intensity of GAPDH (arbitrary units) was used to normalize target protein abundance (*i.e.* target protein abundance = total target protein intensity/GAPDH intensity).

pared with other EAA, there are inconsistent recommendations for optimal requirements.¹⁵ However, previous work indicated that a 2 : 1 Lys : Arg would not be detrimental to milk protein synthesis.^{13–15}

The present study aimed to mimic feeding conditions that could potentially be achieved in the field in order to modify the ratio of EAA available to mammary cells to test the effects of increased supply of Met (Lys : Met = 2.5 : 1) and Arg (Lys : Arg = 1 : 1) using their profiles in the IPAA as a guide. Thus, the levels of Met and Arg used in the present study were in accordance with our previous work.^{16,17} Within those *in vitro* studies, although there was an overall positive effect on mammary cell metabolism, the negative effects on phosphorylation of 4E binding protein 1 (EIF4EBP1), eukaryotic elongation factor 2 (EEF2),¹⁶ mTOR,¹⁷ and mRNA abundance of β -casein and AA transporters¹⁷ were partly consistent with the present results. Similarly, despite using EAA profiles similar to those in IPAA, previous *in vivo* studies also reported results contrary to ours, for instance phosphorylation ratio of ribosomal protein S6 (RPS6) was lower at a Lys : Met = 2.9 : 1⁴¹ and milk protein synthesis or the efficiency of N utilization was not modified at an Lys : Arg = 2 : 1.¹⁵ Thus, it seems plausible that the decrease in CSN1S1 abundance observed in the present study in response to 2.5 : 1 Lys : Met and 1 : 1 Lys : Arg resembles the *in vivo* response. Clearly, from a practical production standpoint, the focus should be in reaching at the very least the levels of Met and Arg that are in the IPAA. However, depending on stage of lactation, *e.g.* early *versus* late lactation, additional supply of Met and Arg could benefit health and production performance.

AA transport and sensing

The availability of AA is instrumental to the efficiency of milk protein synthesis,^{42,43} with Met and Arg being two of the most-limiting and the most-extracted from blood by bovine mammary gland. Due to selective barrier function,⁴⁴ AA require membrane-spanning AA transporters (AAT) for entry into and out of cells. The stage of lactation in dairy cows³⁴ and AA profiles in the MP¹⁷ have been suggested to elicit some direct or indirect control over the transcription of AAT in mammary cells.

Among 7 AAT known to be mTORC1 targets, the opposite response in *SLC7A1* mRNA abundance (Arg and Lys transporter) elicited with incMet or incArg suggested a different sensitivity to additional supply of Arg and Met. The fact that *SLC7A1* mRNA abundance was lower with greater Arg supply agrees with previous studies in ruminants⁴⁵ and non-ruminants.⁴⁶ The down-regulation in mRNA abundance of *SLC7A5*, *SLC3A2*, and *SLC1A5* in response to greater Arg supply suggested a negative feedback on the uptake of AA when other EAA are constant, possibly because cells were trying to deal with too high concentrations of Met or Arg. We also recently detected similar responses with increased supply of Met in MAC-T cells.¹⁷

An important consideration to keep in mind is the fact that *SLC3A2* and *SLC7A5* counter-transport cationic AA out of mammary cells, suggesting the possibility that beyond a certain extracellular concentration the AAT mechanisms might become saturated. More importantly, because *SLC7A5*, *SLC3A2* and *SLC1A5* have a reciprocal regulatory connection with mTORC1⁴⁷ and are stimulated *via* mTOR activity when exogenous AA supplementation increases,⁴⁸ it seems plausible that greater supply of Met and Arg to BMEC could influence milk protein synthesis potentially *via* regulating AA transport through its effect on transcription of those AAT.

In addition to AAT-mediated regulation on milk protein synthesis,⁴⁹ AA play a regulatory role by inducing changes in upstream mTORC1 signaling sensing components.⁵⁰ Of note, the cytosolic Arg sensors for mTORC1 (*i.e.*, CASTOR proteins) link this AA with the mTORC1 pathway.⁵¹ In fact, Arg disrupts the interaction of CASTOR dimers with the GATOR2 complex, presumably allowing free GATOR2 to inhibit the GATOR1 complex.⁵² The GATOR2 complex protein WDR24 is particularly important in sensing AA and activating mTORC1.⁵³ Activation of GATOR2 further activates mTORC1 through the active Rag GTPases⁵⁴ that aid in localizing mTORC1 to lysosomes where the protein Ras homolog, mTORC1 binding (RHEB) is located⁵⁵ (Fig. 1).

In the present study, despite the lack of differences at the protein level, the lower mRNA abundance of *CASTOR1* with increased supply of Arg and Met was consistent with greater phosphorylation status of mTOR, likely because less CASTOR1 interacting with GATOR2 alleviates their negative regulation on

Fig. 1 Theoretical model of arginine and methionine-induced regulation of milk protein abundance *via* upstream mechanistic target of rapamycin complex 1 (mTORC1) signaling and circadian clock network in bovine mammary epithelial cells. The solid lines denote the contributions observed in the present study. Dotted lines denote relationships inconsistent with the literature.

mTOR activity.⁵⁶ Greater supply of Arg was associated with the dissociation of CASTOR1 from GATOR2, which might explain the lower abundance of CASTOR1. Because the protein abundance of CASTOR1, MIOS (subunit of GATOR2), and RAGA did not differ due to Arg or Met alone or in combination, the observed differences at the mRNA abundance level are difficult to explain. However, the differences in p-mTOR:tmTOR and total CSN1S1 abundance indicate that greater activation of mTOR alone might be insufficient to enhance CSN1S1 synthesis. Whether the other 3 casein isoforms would respond in a similar fashion is unknown.

Upstream signaling from mTORC1

In non-ruminants, a large array of factors required for protein synthesis affects the mTORC1 signaling pathway *via* interacting with the tuberous sclerosis (TSC1/TSC2) complex⁵⁷ in which TSC2 acts as a GTPase-activating protein towards RHEB to impact mTORC1 activity.⁵⁸ Our theoretical model (Fig. 1) mainly focuses on two signaling pathways upstream of mTORC1 with TSC2 being a key integration point to link regulators that coordinate nutrient signals (AA availability), cellular energy status, and protein synthesis.

Availability of AA could feed into the core PIK3C3-AKT pathway that assembles AAT and targets TSC2 functioning downstream of AKT and upstream of mTORC1.⁵⁹ Upon activation of PIK3C3, AKT further activates mTORC1 through phosphorylating and inactivating TSC2 on Thr^{14,60,62} or directly phosphorylates mTORC1.⁶¹ The lack of statistically significant effect on mRNA and protein abundance of PIK3C3 and the fact that most AAT for Arg and Met measured in the present study were downregulated with the treatments

suggests that intracellular AA availability might not have been enough. Other signaling events leading from activation of PIK3C3 to downstream changes in cell physiology, particularly the response of intracellular $[Ca^{2+}]_i$ or insulin, merit detailed research.

The lower phosphorylation ratio of p-AKT:tAKT (*i.e.* less active AKT) with greater supply of Arg (particularly when combined with greater Met) might partly explain the greater p-TSC2 in the present study, *i.e.*, less repression of AKT on TSC2. However, the fact that increased Arg supply also nearly doubled the p-mTOR:tmTOR ratio seems contradictory. As Sekulić *et al.* (2000)⁶¹ reported that phosphorylation of mTOR by AKT had no subsequent influence on downstream targets (*e.g.* RPS6K1 and EIF4EBP1), whether the greater p-mTOR:tmTOR might be the result of other kinases remains to be determined. The phosphorylation ratio changes in mTOR were due primarily to a reduction in total mTOR. In that context, too high concentrations of Met and Arg relative to the ideal AA profile might explain the decrease in CSN1S1 and total mTOR protein detected in the present study.

Because the response on p-AMPK:tAMPK ratio due to incArg was similar to p-AKT:tAKT, we speculate that intracellular glucose supply and its metabolism was sufficient to support utilization for anabolic purposes. The kinase AMPK, a conserved cellular energy sensor,⁶² phosphorylates and activates TSC2 that is required to inhibit mTORC1⁶³ and, hence, serves as a signaling nexus for energy homeostasis and nutrient-sensing that inhibits protein synthesis, the most energy-demanding anabolic process.⁶⁴ Although we did not measure cellular energy status *per se*, the greater p-TSC2 with increased supply of Arg seems to confirm that activation of AMPK was

not the sole regulator of TSC2. There might be other kinases specific to mammary cells that regulate this protein. For instance, ERK-dependent phosphorylation leads to dissociation of the TSC1–TSC2 complex, and markedly impairs the ability of TSC2 to inhibit mTOR signaling.⁶⁵ However, contrary to previous work⁶⁶ the possibility exists that ERK–TSC2 signaling was not necessary for controlling p-mTOR in response to increased supply Arg or Met. It is also noteworthy that the addition of Met to the incArg treatment (*i.e.* incArg + incMet) was needed to return CSN1S1 abundance to those of the control or incMet, *i.e.* in spite of achieving the greatest p-mTOR:tmTOR incArg led to lower CSN1S1 abundance. That response agrees with a recent report evaluating dosage of Met on CSN1S1 abundance in mammary cells.⁶⁷

Circadian clock network

Circadian cyclic signals are generated by a series of well-defined oscillators based on transcription-translation feedback loops⁶⁸ (TTFL, Fig. 1). At the center of this molecular machinery, the CLOCK and ARNTL proteins act as transcriptional activators of CLOCK-controlled genes (CCG), which encode repressors PER1 and CRY1.^{69,70} It is noteworthy to point out that metabolic regulation is not a mere output function of the circadian system, but nutrient or energy levels signal back to cellular clock network to reinforce circadian rhythmicity and to adapt physiology to temporal needs.⁷¹ Some signaling molecules, surrounding the core clock network, coordinate cellular nutrient and energy metabolism in mammals,^{72,73} of which AKT and AMPK were the main emphasis in the present study. Those are at the crossroads of upstream mTORC1 signaling and the circadian clock network.

Besides phosphorylating mTORC1, the protein AKT can lengthen the circadian period when activated.⁷⁴ In that context, AKT might be a point through which changes in protein synthetic metabolism impact the functioning of circadian clock. This would occur *via* phosphorylating CLOCK (Ser⁸⁴⁵) and ARNTL (Ser⁴²), which subsequently influences their nuclear/cytoplasmic shuttling.^{75,76} In the present study, the lack of statistical changes in ARNTL protein abundance due to AA treatments was inconsistent with previous work where AKT deficiency decreased ARNTL abundance.⁷⁷ Lower p-AKT protein with increased supply of Arg could alleviate inhibition on clock function, but the opposite response of CLOCK protein abundance with increased Met or Arg alone or in combination might have occurred because AKT might not be the sole regulator of CLOCK and ARNTL in mammary cells. The alteration of CLOCK and ARNTL abundance with increased supply of Met and Arg might occur mainly through other pathways. Future work should investigate the effects of Met and Arg on other regulators of CLOCK and ARNTL.

The AMPK protein transmits energy-dependent signals to the CLOCK partly through coordinating with SIRT1 and NAMPT to inhibit transcriptional activity of CLOCK–ARNTL heterodimers. A role for SIRT1 on the AMPK-mediated responses in mammary cells⁷⁸ cannot be discounted. Active AMPK enhances SIRT1 activity by increasing cellular NAD⁺

levels through the upregulation of NAMPT, a rate-limiting enzyme in NAD⁺ biosynthesis.^{79–81} There is, in fact, a mutualistic interaction between activated SIRT1 and AMPK, because the former can activate AMPK *via* the enzyme STK11.^{82,83} In the context of the present study, the lower p-AMPK:tAMPK with increased Arg supply might have been responsible for the lower mRNA abundance of *SIRT1* and *NAMPT*. Activated SIRT1 counteracts CLOCK and ARNTL function through its histone deacetylase activity, which inhibits transcriptional activity of CCG.^{84,85} This role of SIRT1 is particularly relevant because an important function of CLOCK–ARNTL heterodimers is to activate NAMPT.^{86,87} Therefore, SIRT1 seems to sit at the center of a loop coordinating the activity of AMPK and CLOCK–ARNTL complexes. Thus, lower expression of *SIRT1* in this study may partly explain the greater abundance of CLOCK and PER1 proteins with greater supply of Met or Arg.

Overall, the aforementioned link between mTORC1-mediated protein synthesis and circadian clock feedback loops might partly occur through the AMPK protein, which coordinates intracellular energy levels. Because protein synthesis is closely associated with intracellular energy metabolism, it is reasonable to foresee future studies in which energy supply to the mammary gland (*e.g.* glucose) can be manipulated while holding EAA profiles constant to better study the role of AMPK in milk protein synthesis and the circadian clock network.

Conclusions

Increasing the supply of Met and Arg to reach ratios of 2.5 : 1 Lys : Met and 1 : 1 Lys : Arg while maintaining concentrations of other EAA constant induces alterations in mRNA abundance of AA transporters and activity of upstream AA-sensing components in the mTORC1 and circadian clock signaling pathways. The decrease of α -s1-casein protein abundance might indicate a response of cells to a high concentration of AA. From a practical standpoint, targeting the supply of Met and Arg to the ideal ratio of Lys : Met and Lys : Arg (*i.e.* IPAA) during established lactation should help optimize casein protein synthesis. However, recent data underscore the potential for enhancing the supply of Met and Arg beyond those in the IPAA as a way to enhance health and production performance, *i.e.* these EAA might exert a functional role beyond serving solely as precursors for protein synthesis. Considering that protein synthesis is one of the most energy-consuming cellular processes and intracellular energy levels link mTORC1-mediated protein synthesis and circadian clock feedback loops, future studies should control energy status and total AA supply to explore further the underlying mechanistic relationships in the context of milk protein synthesis.
