Capped silver nanoparticles (AgNPs) are used in many applications in the biomedical field because of their unique structural flexibility. Herein, a viable chemical reduction synthesis method for AgNPs is described employing ionic surfactants as stabilizing as well as capping agents. Stabilized AgNPs of a quasi-spherical shape were obtained using silver nitrate (AgNO<sub>3</sub>) as a precursor and sodium borohydride (NaBH<sub>4</sub>) as a reducing agent under multiple ionic micellar hierarchical approaches. UV-Visible spectroscopy studies showed characteristic single and sharp absorbance peaks in the range 400 to 420 nm, which indicates the absence of the self-aggregation of AgNPs, whereas the FTIR results indicated the surfactant functionalities responsible for the stability of the AgNPs. Micrographs of the as-obtained AgNPs, obtained via electron microscopy (SEM, STEM), demonstrated a fine monomodal collection of spherical nanoparticles of <15 nm, which was further confirmed by dynamic light scattering (DLS) measurements. Moreover, the stability of the as-synthesized AgNPs was evaluated by determining the charge present on the surface, *i.e.*, positive or negative, indicating the stability of the monodispersed AgNPs against flocculation. The bactericidal ability of the surfactant capped AgNPs was checked by measuring the zone of inhibition using the agar-well diffusion method. The results indicated that CTAB-AgNPs and SDS-AgNPs showed enhanced bactericidal effects, whereas DDAB-AgNPs, DOSS-AgNPs, and MES-AgNPs showed no significant activity against multidrug-resistant strains of bacteria.

## Introduction

Since ancient times, metal has attracted great interest as an ornament or jewellery. In contrast, the nanostructures of these metals have been of interest due to their larger surface area to volume ratio, size, shape, and electrical properties, especially in the field of biomedicine. Due to significant size-related perspectives, various metal nanoparticles (NPs) are being synthesized and adopted for use.<sup>1,2</sup> Among the precious metal nanoparticles, silver nanoparticles (AgNPs) have become the focus of scientific attention because they have the ability to interact with various biomolecules against a broad spectrum of

bacteria and because of their fungicidal activity.<sup>3</sup> Although scientists are fascinated by AgNPs due to their multifunctional properties and their widespread uses in electronics,<sup>4</sup> the textile industry,<sup>5,6</sup> waste water treatment,<sup>7</sup> as potent disinfectants,<sup>8</sup> and dentistry,<sup>9</sup> however, expansion of multidrug-resistant bacteria, being an alarming situation, has shifted the scientists' attention to the use of AgNPs in biomedical applications.<sup>3</sup>

The AgNPs are being synthesized, physically and/or chemically, using multiple stabilizers with various protocols, *i.e.*, hydrothermal with nanocellulose,<sup>10</sup> chemical reduction and stabilization by dextran,<sup>11</sup> and photochemical in the presence of collagen.<sup>12</sup> Despite all this, the stability of the NPs have been a great concern which is related to the synthesis of AgNPs, because of the expense and the harmful environmental impacts of them being employed as stabilizers.<sup>13</sup>

Surfactants, and amphiphilic molecules, primarily function as stabilizers and provide colloidal stability and prevent agglomeration and excessive growth. In addition, it was also found that these amphiphilic molecules acted as optimal capping agents, thereby greatly improving the antibacterial activity of the modified AgNPs. However, it is also evident that

† Electronic supplementary information (ESI) available: FTIR spectra and basic molecular structures of the pure surfactants, SEM results from DDAB-AgNPs, DOSS-AgNPs, and MES-AgNPs, and antibacterial activity results. See DOI: 10.1039/d0ma00408a

the bactericidal and fungicidal properties are morphologically dependent on the AgNPs. Fortunately, surfactants can be control the morphology of colloidal NPs.<sup>14–16</sup> Although various silver nanostructures such as silver nanorods, nanoplates, and triangular shapes have been reported to enhance bactericidal properties, conversely it has been concluded from previous reports in the literature that spherical AgNPs have a poorer bactericidal performance compared to other shapes and morphologies.<sup>14,17,18</sup>

In the context of differential morphological dependent bactericidal properties of AgNPs, the current work describes the development of quasi-spherical AgNPs *via* a one-pot wet chemical reduction route under multiple ionic micellar hierarchical approaches. The purpose is to enhance the bactericidal efficiency of spherical AgNPs. Different capping agents *i.e.*, cetyltrimethylammonium bromide (CTAB), di-*n*-dodecyldimethylammonium bromide (DDAB), sodium dodecyl sulfate (SDS), dioctyl sodium succinate (DOSS), 2-mercaptoethanesulfonate sodium (MES) are used (basic molecular structures are given in Table S1 (ESI<sup>†</sup>)). The characterization of the synthesized AgNPs was accomplished using UV-Visible, and Fourier transform infrared (FTIR) spectroscopies, DLS, and zeta potential measurements, whereas the morphology of AgNPs was determined using scanning electron microscopy (SEM) and scanning transmission electron microscopy (STEM). The bactericidal activity against nine bacterial strains was checked using the agar-well diffusion method, and the zone of inhibition (ZOI) was determined accordingly. Based on the data provided in this study, it was found that spherical AgNPs show enhanced bactericidal efficiency when capped with mono-alkyl ionic surfactants compared to capping with the di-alkyl surfactant moiety.

## Experimental section

### Materials and chemicals

Silver nitrate (AgNO<sub>3</sub>, 99%) and sodium borohydride (NaBH<sub>4</sub>, ≥98%) were purchased from VWR Chemicals. Cetyltrimethylammonium bromide (CTAB, ≥99%) was purchased from VWR, di-*n*-dodecyldimethylammonium bromide (DDAB, 98%) from Alfa Aesar, sodium dodecyl sulfate (SDS, ≥99%) from Duksan Pure Chemicals, dioctyl sodium succinate (DOSS, 96%) and 2-mercaptoethanesulfonate sodium (MES) from Acros organics. All the chemicals were of analytical grade and used as received without any further modifications. Double distilled H<sub>2</sub>O was used for the preparation of all the solutions.

### Synthesis of capped-AgNPs

For the synthesis of AgNPs, AgNO<sub>3</sub> was used as the precursor of silver ions, NaBH<sub>4</sub> was used as the reducing agent, and different surfactants were utilized as capping agents. A portion (2.0 mL) of AgNO<sub>3</sub> (1 wt%) was diluted to 100 mL with distilled water. Then the optimal amount of each capping agent was prepared in 100 mL of distilled water. The AgNO<sub>3</sub> and capping agent (one per sample) solutions were then mixed together and continuously stirred at room temperature, maintaining the concentration of each surfactant, *i.e.*, CTAB (2.0 mM), DDAB

Fig. 1 The visual appearances of various capped-AgNPs.

(0.3 mM), SDS (9.0 mM), DOSS (3.0 mM) and MES (1.0 mM) above their respective critical micelle concentration (CMC) values. After 10 min, freshly prepared NaBH<sub>4</sub> solution (0.04 g in 1 mL of H<sub>2</sub>O) was added dropwise, resulting in the formation of capped-AgNPs. After all the NaBH<sub>4</sub> solution was added, the reaction mixture was stirred overnight. At the end of the reaction, a brownish colloidal solution was obtained, as shown in Fig. 1. The as-synthesized capped-AgNPs were labelled as A1, A2, A3, A4 and A5 for CTAB-AgNPs, DDAB-AgNPs, SDS-AgNPs, DOSS-AgNPs and MES-AgNPs, respectively.

### Characterization of capped-AgNPs

**Spectroscopic measurements.** The IR spectra of AgNO<sub>3</sub>, pure surfactant solutions and as-synthesized capped-AgNPs at a frequency range of 400–4000 cm<sup>-1</sup> were observed with a Bruker Alpha series FTIR spectrometer. The characteristic plasmonic peaks of the synthesized AgNPs were measured by UV-Visible spectroscopy.

**Particle size analysis.** A Malvern Instruments, Nano ZSP Zetasizer was used to record the average particle size, polydispersity index (PDI) and zeta potential of the capped-AgNPs. At a temperature of 25 °C, a clear disposable zeta cell was used to measure the size distributions of samples with a laser having a wavelength of 635 nm.

**Morphology of capped-AgNPs.** The structural information of the capped-AgNPs was assessed using a 15 kV FEI, Nova NanoSEM 450 SEM equipped with an A-B mode STEM detector. The sample was restricted by dripping it onto a carbon-coated copper mesh and air-drying. After coating with a 1% ammonium molybdate solution, it had swollen and was then dried for 10 s. It was further dried before the microscopic studies.

### Antibacterial activity

The antibacterial activity of the synthesized AgNPs was measured by an agar-well diffusion method. A suspension of microorganisms with a concentration of 10<sup>5</sup>–10<sup>6</sup> colony forming units (CFU) per well was used. The volume of the microbial inoculum was distributed on the surface of the agar plate. A 5 mm diameter hole in the agar was made with a sterile cork, and a volume of synthetic AgNP dispersion was used as a sample. The culture

plate was incubated at 37 °C for 24 h, and then the ZOI was evaluated visually to check for bacterial activity.

## Results and discussion

### UV-visible spectroscopy to measure plasmonic peaks

The UV-visible spectroscopy was utilized to obtain the absorption spectra of AgNO<sub>3</sub> (precursor) and all the as-synthesized capped-AgNPs, shown in Fig. 2(a). Optical and structural information about the samples were also obtained from the electronic spectrum. The AgNO<sub>3</sub> showed a characteristic plasmonic peak at 302 nm.<sup>19</sup> The sample A1 (slightly yellow), A2 (yellow), A3 (orange), A4 (light brown) and A5 (dark brown) (by eye indistinguishable from the blank shown in Fig. 1), showed maximum absorption at 415, 406, 410, 414 and 406 nm, respectively, as shown in Fig. 2(a). A single plasmonic resonance peak was obtained for each sample, which showed the uniformity of the particles formed and a certain degree of monodispersity. Compared with the absorption of AgNO<sub>3</sub>, the absorption of each nano-sample was red-shifted, which confirmed the reduction of silver ions and the formation of silver particles.<sup>19</sup> The concentration of silver particles was calculated using Lambert–Beer's law, and the data obtained is given in Table 1.

### Infrared study

The FTIR spectroscopy was used to observe the presence of functional groups and the changes in the peaks that occurred due to the changes in the nature of the surfactants. The FTIR spectra of AgNO<sub>3</sub> (precursor) and all the synthesized, capped-AgNPs are shown in Fig. 2(b). In the spectrum of AgNO<sub>3</sub> solution, two peaks were observed at 3223.11 and 1632.44 cm<sup>-1</sup>. Due to the presence of the aqueous medium, a broad absorption peak was observed at 3221.31 cm<sup>-1</sup>, which corresponded to O–H stretching. The peak at 1632.79 cm<sup>-1</sup>, corresponded to the stretching of the N–O group. In the spectra of the synthesized silver dispersion, the peak at 3223.11 cm<sup>-1</sup> became broader, whereas the peak at 1636.79 cm<sup>-1</sup> underwent a red shift and a decrease in intensity occurred. In the spectra of A1 and A2, two new peaks appeared at 1081.19 cm<sup>-1</sup> and 1083.58 cm<sup>-1</sup>, respectively, corresponding to C–N stretching. In the case of A3, A4 and A5, new peaks appeared at 1084.60, 1087.22 and 1093.83 cm<sup>-1</sup>, respectively, which corresponded to the stretching vibration of the S=O group. The spectra of the pure surfactant solution are also given in the Fig. S1 (ESI<sup>†</sup>), which confirmed the change in the nano-sample spectrum. The broadening, shifting and appearance of new peaks in the spectra of the nano-samples indicated an interaction between the surfactant and surface of the silver particles.<sup>20</sup>

Fig. 2 UV-visible (a) and FTIR (b) spectra for AgNO<sub>3</sub> and capped-AgNPs.

Fig. 3 Particle size distributions (a) and zeta potentials (b) of surfactant capped AgNPs.

### Dynamic light scattering study

The average particle size of the synthesized AgNPs was determined by a DLS technique. From the results, it was confirmed that the sizes of the silver particles formed were in the nanometer range of 4–12 nm. The formation and capping of the silver particles had already been confirmed by the results of the UV-visible and FTIR techniques, respectively. As shown in Fig. 3(a), in the presence of the capping agents CTAB, DDAB, SDS, DOSS and MES, the average particle size of the AgNPs is  $5.5 \pm 0.50$ ,  $9.20 \pm 0.20$ ,  $6.70 \pm 0.30$ ,  $4.50 \pm 0.50$  and  $11.30 \pm 0.30$  nm, respectively.

### Zeta potential

The zeta potentials of the synthesized AgNPs: A1, A2, A3, A4 and A5 are plotted in Fig. 3(b). The surfactants were adsorbed on to the surface of AgNPs through a hydrophobic interaction between the hydrophobic groups of the surfactant and the negative surface of the AgNPs. As reported earlier, the stability of the AgNPs increased with the surface charge of AgNPs due to the presence of surfactants.<sup>21</sup> Anionic surfactants generated a negative charge, whereas the cationic surfactants generated a positive charge on the surface of the AgNPs.<sup>22</sup> The zeta potentials of the nano-samples: A1, A2, A3, A4 and A5 were found to be: +16.8, +31.6, -33.1, -45.2 and -28.5 mV, respectively. The zeta potential, and hence the stability of the synthesized AgNPs in the presence of the capping agent decreased in the order: DOSS > DDAB > SDS > MES > CTAB. Compared with DDAB, the AgNPs had a high stability when DOSS was present as a dialkyl chain surfactant. Whereas, for the single alkyl chain, SDS was a more suitable surfactant when compared to CTAB

and MES, because the larger the charge value appearing on the surface of the AgNPs the greater the stability of the particle.<sup>21</sup>

### Scanning transmission electron microscopy

The morphological information about the synthesized AgNPs was obtained from the STEM and SEM micrographs, as shown in Fig. 4(a, b) and (a', b'), respectively. The photomicrographs

Fig. 4 STEM (a and b) and SEM (a' and b') micrographs of CTAB-AgNPs (A1) (a and a') and SDS-AgNPs (A3) (b and b').

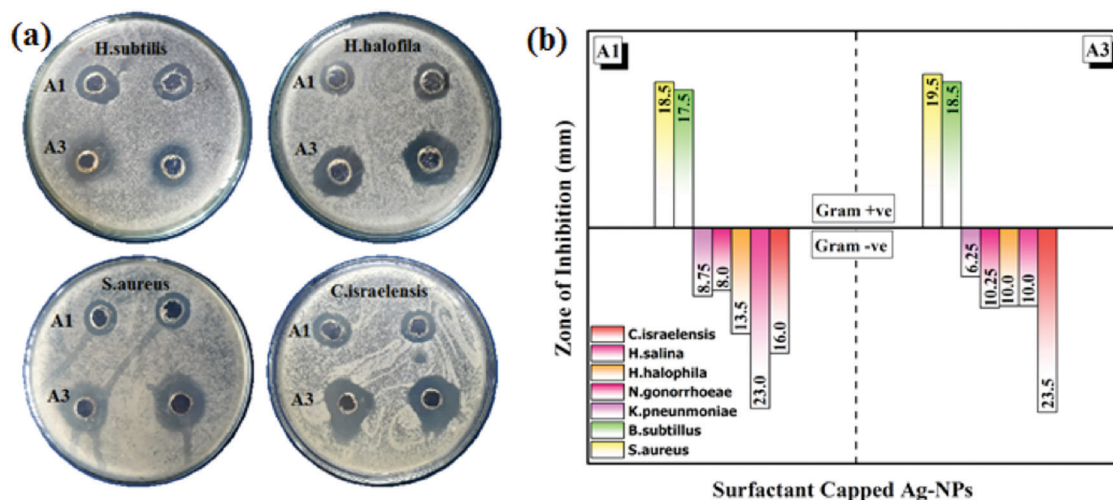

Fig. 5 The antibacterial activities of CTAB-AgNPs (A1) and SDS-AgNPs (A3): (a) zone of inhibition against *B. subtilis*, *H. halophila*, *S. aureus*, and *C. israelensis*; and (b) comparative results of the zone of inhibition against Gram-positive and Gram-negative bacteria.

confirm that the synthesized surfactant capped-AgNPs (CTAB-AgNPs and SDS-AgNPs) were quasi-spherical and monodispersed in nature. The SEM micrographs of the DDAB-AgNPs, DOSS-AgNPs and MES-AgNPs are given in Fig. S2 (ESI<sup>†</sup>), which depict the quasi-spherical shape and monodispersity of the synthesized NPs.

### Antibacterial activity

The *in vitro* antibacterial activity of the synthesized AgNPs was tested against nine (9) strains of bacteria: *Staphylococcus aureus* (*S. aureus*), *Bacillus subtilis* (*B. subtilis*), *Klebsiella pneumoniae* (*K. pneumoniae*), *Neisseria gonorrhoeae* (*N. gonorrhoeae*), *Halomonas halophila* (*H. halophila*), *Halomonas salina* (*H. salina*), *Chromohalobacter israelensis* (*C. israelensis*), *Shigella sonnei* (*S. sonnei*) and *Escherichia coli* (*E. coli*). Table S2 (ESI<sup>†</sup>) shows the measurements of the ZOI for all the nano-samples with a positive control (Streptomycin). The size of the sample taken was 30  $\mu$ L. It was observed that samples A1 and A3 showed activity against seven (7) bacterial strains as shown in the Fig. 5. Whereas, samples A2, A4 and A5 did not show any significant bactericidal properties against the tested bacterial strains. It

can be seen that CTAB-AgNPs and SDS-AgNP were more active against Gram-negative bacteria than Gram-positive bacteria. This can be explained by differences in the peptidoglycan thickness in the bacterial cell wall (Fig. 5a). Compared to Gram-positive bacteria, Gram-negative bacteria have thinner cell walls, as reported previously.<sup>23</sup> Thus, the surfactant-capped quasi-spherical AgNPs obtained have bactericidal properties due to the fact that they interact with bacterial cells and cause their destruction. According to previous reports, they affect the normal function of bacterial cells by reacting with soft alkali and interacting with respiratory enzymes, interact with bacterial cells, inhibit bacterial growth, and change bacterial DNA.<sup>24,25</sup>

Although AgNPs exhibit antimicrobial properties compared to other precious metal NPs, this ability is entirely dependent on size and morphology of the particles. It can be confirmed from the comparative literature (listed in Table 2<sup>26–32</sup>) that spherical AgNPs have a lower bactericidal performance with different methods in the presence of different stabilizers and capping agents. However, in the current work, using surfactants as capping agents, especially monoalkyl chain ionic surfactants (*i.e.*, CTAB and SDS), the bactericidal properties

of spherical AgNPs have been significantly enhanced, as shown in Fig. 5.

## Conclusions

A one-pot, wet chemical reduction method was used to synthesize monomodal, quasi-spherical surfactant-capped AgNPs with an average diameter of < 15 nm. The comparative stability and bactericidal ability of capped-AgNPs were determined using their zeta potentials and inhibition zone values, respectively. The results show that among the di-alkyl chain surfactants, DOSS (−45.2 mV) is more suitable than DDAB (+31.6 mV), whereas among the mono-alkyl chain surfactants, SDS (−33.1 mV) is more suitable than CTAB (+16.8 mV) and MES (−28.5 mV). Compared to dialkyl chain surfactants, mono-alkyl chain surfactants have stronger bactericidal capabilities. Conversely, CTAB-AgNPs and SDS-AgNPs showed significant activity against *S. aureus* (Gram-positive strain), with ZOI of 18.5 and 19.5 mm, respectively, whereas against Gram-negative strains, CTAB-AgNPs showed significant activity (ZOI of 23.0 mm) towards *H. salina*, and SDS-AgNPs showed activity towards *C. israelensis*, with a ZOI of 23.5 mm. Although DOSS is more suitable for the stability of the AgNPs, in contrast, AgNPs capped with SDS and CTAB have a greater ability to inhibit bacterial growth. Above all, the analyses show that surfactants play a key role in enhancing the stability and bactericidal capabilities of spherical AgNPs.

## Conflicts of interest

There are no conflicts to declare.
