## Serial in-solution digestion protocol for mass spectrometry-based glycomics and proteomics analysis†

Manveen K. Sethi, Margaret Downs and Joseph Zaia \*

Advancement in mass spectrometry has revolutionized the field of proteomics. However, there remains a gap in the analysis of protein post-translational modifications (PTMs), particularly for glycosylation. Glycosylation, the most common form of PTM, is involved in most biological processes; thus, analysis of glycans along with proteins is crucial to answering important biologically relevant questions. Of particular interest is the brain extracellular matrix (ECM), which has been called the "final Frontier" in neuroscience, which consists of highly glycosylated proteins. Among these, proteoglycans (PGs) contain large glycan structures called glycosaminoglycans (GAGs) that form crucial ECM components, including perineuronal nets (PNNs), shown to be altered in neuropsychiatric diseases. Thus, there is a growing need for high-throughput methods that combine GAG (glycomics) and PGs (proteomics) analysis to unravel the complete biological picture. The protocol presented here integrates glycomics and proteomics to analyze multiple classes of biomolecules. We use a filter-aided sample preparation (FASP) type serial in-solution digestion of GAG classes, including hyaluronan (HA), chondroitin sulfate (CS), and heparan sulfate (HS), followed by peptides. The GAGs and peptides are then cleaned and analyzed using liquid chromatography-tandem mass spectrometry (LC-MS/MS). This protocol is an efficient and economical way of processing tissue or cell lysates to isolate various GAG classes and peptides from the same sample. The method is more efficient (single-pot) than available parallel (multi-pot) release methods, and removal of GAGs facilitates the identification of the proteins with higher peptide-coverage than using conventional-proteomics. Overall, we demonstrate a high-throughput & efficient protocol for mass spectrometry-based glycomic and proteomic analysis (data are available via ProteomeXchange with identifier PXD017513).

### 1. Introduction

Over the years, a number of methods for integrated mass spectrometry-based glycomics and proteomics have been introduced.<sup>1,2</sup> With the advent of new experimental techniques, methods, technologies, and instrumentation, the integrated effort to analyze glycans (glycomics), and glycoproteins (glycoproteomics) along with proteins (proteomics) has gained momentum.<sup>2–7</sup> Still, insufficient attention has been paid to glycosaminoglycans (GAGs) and proteoglycans (PGs), which are multi-anionic and highly sulfated and, thus, immensely challenging to study by liquid chromatography-tandem-mass spectrometry (LC-MS/MS). Examples of analytical limitations include low-PG-sensitivity on LC-systems, low PG-peptide-sequence

coverage, and significant sulfate losses in tandem-MS.<sup>8</sup> Thus, PG profiling remains immature relative to other 'omics (genomics/proteomics/N- or O-glycomics) approaches,<sup>9</sup> impeding advances in our understanding of the structural and biological roles of GAGs and PGs in various biosystems. We developed a mass spectrometry-compatible method for the extraction of GAGs from wet tissue.<sup>10</sup> In order to combine glycomics and proteomics, we next demonstrated serial extraction and analysis of multiple classes of GAGs and peptides from tissue slides,<sup>11,12</sup> a method that allows precise targeting of regions in tissue slides. We now describe a new streamlined, filter aided sample preparation-based method optimized for the recovery of GAG saccharides and peptides from biological samples that must be analyzed as a wet tissue.

Proteoglycans (PGs) are glycoproteins containing GAG structures that are linear polysaccharides constituting of sulfated disaccharide repeating units. Because the biosynthetic reactions do not go to completion, the GAG chains are heterogeneous concerning chain length and modifications. GAGs can be either

Boston University School of Medicine, Boston University, Department of Biochemistry, Boston, 02118, USA. E-mail: [jzaia@bu.edu](mailto:jzaia@bu.edu)

† Electronic supplementary information (ESI) available. See DOI: 10.1039/d0mo00019a

protein-bound or present in the free form.<sup>13</sup> Thus, they may play essential roles in all areas of physiology through their biophysical properties and capacities to bind growth factors and growth factor receptors. There is a growing interest in documenting the roles of GAGs and PGs and their binding partners in neurological disease mechanisms.<sup>14</sup> Based on differences in the type of monosaccharide units and their modification, GAGs can be divided into categories based on the repeated disaccharide unit, *i.e.*, heparan sulfate (HS), chondroitin sulfate (CS), dermatan sulfate (DS), keratan sulfate (KS) and hyaluronic acid (or hyaluronan) (HA). HS consists of repeating disaccharide units of uronic acid (glucuronic or iduronic acid) with *N*-acetylglucosamine; CS/DS consists of *N*-acetylgalactosamine with glucuronic or iduronic acid; HA is unsulfated and present in free form without any core protein; KS consists of repeating units of *N*-acetylglucosamine with galactose.<sup>13,15</sup> Fig. 1 shows structures for HA, CS/DS, and KS.

The extracellular matrix (ECM) consists of a network of glycoproteins, PGs, collagens, and HA. These molecules form an organized network that acts as a scaffold, mediates cell-to-cell communication, binds secreted proteins such as growth factors, and regulates the activity of protein complexes. Many matrix proteins have lectin domains that recognize glycan epitopes,

forming robust molecular networks. The ECM also contains enzymes that modify glycosylation patterns on proteins,<sup>16</sup> but the exact glycan makeup of mature matrix glycoproteins and PGs, and their spatial and temporal variations, remain ill-defined. Antibody-based and staining studies have shown spatial and temporal regulation of glycosylation in various organs<sup>17,18</sup> that indicate the presence or absence of a particular glycan epitope but do not define explicitly the underlying structure. Established mass spectrometry-based proteomics methods suffice for qualitative assignment of glycosites but do not provide complete glycosylation coverage.<sup>19</sup>

We seek to establish a streamlined protocol to analyze PG GAG chains, *N*-glycans, and core proteins in the brain or any other mammalian tissue. Exhaustive digestion of tissue using GAG lyase enzymes releases disaccharides that can be quantified using LC-MS. The abundances of the disaccharides released by specific lyase enzymes can be used to estimate the domain structure of the GAG chains.<sup>20,21</sup> Compared to our on-slide digestion protocol that provides a selection of target area on a tissue slides<sup>11,12,22,23</sup> and MALDI-imaging method for glycans that provides higher spatial resolution,<sup>24–26</sup> this method can be applied to free-floating or frozen tissues and provides a higher recovery of glycans and proteins than the on-slide method. Moreover, widely used MALDI-imaging

**Fig. 1** Structure of key GAGs. (A) Hyaluronic acid (HA) disaccharide units, HA chains. (B) Heparan sulfate (HS) disaccharide unit, HS chains, and linker tetrasaccharide structure. (C) Chondroitin, and dermatan sulfate (CS/DS) disaccharide unit, CS/DS chains, and linker tetrasaccharide structure. (D) Keratan sulfate (KS) disaccharide units, KS chains. Abbreviations: Fuc, fucose; GlcA, glucuronic acid; IdoA, iduronic acid; GalNAc, *N*-acetylgalactosamine; GlcNAc, *N*-acetylglucosamine; Sia, sialic acid; Xyl, xylose; Ser, serine; Ac, acetyl; S, sulfate (SO<sub>3</sub>H).

dissociates fragile glycan substituent's including sulfates, and is not recommended for analysis of GAGs.<sup>27</sup> The serial in-solution digestion platform suggested here is more rapid (less sample-processing time), and efficient (single-pot)<sup>28,29</sup> than the currently used parallel approach, *i.e.*, a multi-pot simultaneous enzymes application methods.<sup>10,28–30</sup> The removal of GAGs facilitates protein identification of the remaining deglycosylated PGs with higher peptide-coverage,<sup>31</sup> compared to current studies achieving only low PG-coverage.<sup>32,33</sup> In addition, the removal of GAGs creates a linker-glycosite that leaves a linker tetrasaccharide plus one disaccharide to the protein/peptide, assisting with the identification of site-specific glycosylation of PGs.<sup>31,34</sup> Table 1 provides a comparison of our method, including starting material, sample processing time, derivatisation/enrichment steps, loading amounts, and detection range for proteins, GAGs, and *N*-glycans, with other tissue digestion protocols available for integrated (or individual) glycomics and proteomics.

Our protocol follows a filter-aided sample preparation (FASP) type serial in-solution digestion of glycosaminoglycan (GAG) classes, including hyaluronan (HA), chondroitin sulfate (CS), and heparan sulfate (HS) followed by peptides from tissue or cell lysates (Fig. 2). Filter-aided sample preparation (FASP) first described by the Mann group in 2009<sup>35</sup> that used molecular weight cut-off (MWCO) membrane as a 'reactor' on which complex protein mixtures were chemically modified and digested. They utilized urea to remove SDS completely, and

then generated tryptic peptides from complex protein mixtures for mass spectral analysis. This method has been modified since and has also been applied for the enrichment of *N*-glycoproteins prior to enzymatic deglycosylation and proteomics analysis.<sup>36–38</sup> We seek to exploit the concept of using MWCO membrane filters as a reactor to digest each GAG classes and collect it as flowthrough, and finally collect proteins and perform trypsin digestion. The abundances of the extracted GAG disaccharides and peptides are determined using liquid chromatography-tandem mass spectrometry (LC-MS/MS) quantifying 1 HA disaccharide, the 6 most abundant CS unsaturated disaccharides (Fig. 3; representative EICs for 6 CS disaccharide standards) and 3 saturated CS disaccharides (see Fig. S1A, ESI† for EICs of CS saturated disaccharide structures), the 8 most abundant HS unsaturated disaccharides (Fig. 4; representative EICs for 8 HS disaccharide standards) and 3 saturated HS disaccharides (see Fig. S1B, ESI† for EICs of HS saturated disaccharide structures, and approximately 1000–1500 proteins (Fig. 5; TIC for mouse brain tissue lysate peptides). In the protocol presented here, mouse brain lysate, and various standard proteoglycans and proteins, for example, syndecan, aggrecan, neurocan, and AGP are used at different steps of the protocol to target different biomolecules (Table 2). Each enzymatic digestion was incubated overnight with enzymes applied directly on the MWCO filters, and each biomolecule takes one day of sample preparation/processing time.

**Table 1** A comparison of our presented in solution method with other available brain tissue digestion glycomics and proteomics methods

Method	Starting material	Sample processing time	Total number of samples processed at a given time	Derivatisation/ fractionation/ enrichment prior to LC-MS/MS	Injection volume	Detection range (proteins, GAGs, <i>N</i> -glycans)	Ref.
In solution digestion of GAGs and protein	20–100 µg of standard protein or mouse brain lysate	Total time = 24 days, 1 day per biomolecule class		No	100 ng of protein, 30% of purified resuspended GAGs	1000–1500 proteins, Presented all unsaturated and saturated GAG disaccharides	manuscript
On-slide tissue digestion	1.8 mm area on slide corresponding to 10 nL tissue volume	Total time = 36 days, 1 day per biomolecule class		No	10% of resuspended peptide, and <i>N</i> -glycans, and 30% resuspended GAGs	1000–1200 proteins, 12 and 46 all unsaturated GAG disaccharide, saturated GAGs are rarely observed	
In-solution tissue digestion of protein using FASP	100 µg of mouse brain tissue lysate	2–3 days only for peptide/protein	Not stated	Yes	5 µg of peptides	1264, 2957 proteins from FASP and MED FASP, respectively, of brain tissue lysate	47
Tissue glyco capture for <i>N</i> -glycans	Whole mouse brain tissue	2 days	Not stated	Yes	Aliquot representing 40 µg brain tissue	200 <i>N</i> -glycans, 90 distinct <i>N</i> -glycan compositions	48
MALDI-IMS	FFPE tissue microarray (TMA) sections (15 × 15 mm, 4–8 µm thick), 100 µm resolution	1–2 days per bio-molecule class	Using a 0.6 mm core allows arraying at higher density more than 500 tissue core can be arranged on a standard microscopic slide	Yes	Not stated	100 proteins, 25–50 <i>N</i> -glycan	49
Filter Aided <i>N</i> -glycan separation (FANGS)	25–250 µg protein	2–3 days for derivatized <i>N</i> -glycans	Not stated	Yes	400 ng of protein for proteomics, 5 µL of resuspended (100%) of <i>N</i> -glycan samples	200–300 proteins, 100–150 glycoproteins, 25 <i>N</i> -glycans.	50

## 2. Materials

### 2.1 Reagents

- Tris-HCl, pH 7.5 (BP1757-100, Fisher BioReagents)
  - Tris-HCl, pH 8.0 (BP1758-100, Fisher BioReagents)
  - Triton X-100 (AC21568-2500, Acros Organics)
  - Sodium dodecyl sulfate (L3771, Sigma Aldrich)

- EDTA (V4231, Promega)
- Sodium chloride
- Pierce proteinase inhibitor mini-tablets (PIA32955, Thermo-Fisher Scientific)
  - Pierce micro BCA protein assay kit (PI23235, Thermo-Fisher Scientific)
  - Ammonium acetate (631-61-8, Fisher Chemicals),

Fig. 4 Extracted ion chromatograms (EICs) for heparan sulfate (HS) disaccharide standards using GlycanPac AXH-1 (ThermoScientific) column mounted on an Agilent 1200 LC attached to an Agilent 6520 Q-TOF.  $\blacktriangleleft$ ;  $\Delta$ -uronic acid,  $\blacksquare$ ; *N*-acetyl glucosamine.

Fig. 5 Total ion chromatogram (TIC) for mouse brain tissue lysate after serial in-solution digestion protocol.

- Ammonium bicarbonate (A6141, Sigma Aldrich)
- Calcium chloride (C5080, Sigma Aldrich),
- Dithiothreitol (D0632, Sigma),
- Iodoacetamide (163-2109, Biorad),
- Trifluoro-acetic acid (A116-10X AMP, Fisher Scientific)
- Acetonitrile (A955-1, LC-MS grade, Fisher Scientific),
- Water (W6-1, LC-MS grade, Fisher Scientific),
- Formic acid (A117-10x-1AMP, LC-MS grade, Fisher Scientific)
- Hyaluronidase (H1136-1AMP, Sigma)
- Chondroitinase ABC (Sigma)

- Heparan lyases 1,2,3 (P0735L, P0736L, P0737L New England Biolabs)
- Trypsin (PRV5280, Promega)/trypsin-LysC (PRV5072, Promega)/Glu-C (PRV1651, Promega)
- High molecular weight hyaluronan (GLR002, R&D systems)
- Mouse brain tissue lysate (89-014-501, Abnova)
- Human neurocan recombinant protein (6508NC050, R&D systems)
- Aggrecan from bovine articular cartilage (A1960-1MG, SigmaAldrich)
- Human Syndecan-1 Protein (#7879, BioVision Incorporated)

**Table 2** Sample setup, including various standard proteoglycans and proteins, and mouse brain tissue lysate used for testing the protocol for each step i–iv (see Fig. 2). HSBK; heparan sulfate from bovine kidney, HSPIM; heparan sulfate from porcine intestinal mucosa, AGP;  $\alpha$ -acid glycoprotein

Batch 1	Batch 2	Targeted biomolecules	Steps
Lysate (100 $\mu$ g $\times$ 1)	Lysate (100 $\mu$ g $\times$ 1)	HA, CS, HS, peptides	i, ii, iii, iv
Hyaluronan (100 $\mu$ g $\times$ 1)	Hyaluronan (100 $\mu$ g $\times$ 1)	HA	i
Syndecan-1 (20 $\mu$ g $\times$ 1)	Syndecan-2 (20 $\mu$ g $\times$ 1)	CS, HS (only for batch1), peptides	ii, iii, iv
Aggrecan (20 $\mu$ g $\times$ 1)	Syndecan-1 (20 $\mu$ g $\times$ 1)	CS, peptides	ii, iv
Neurocan (20 $\mu$ g $\times$ 1)	—	CS, peptides	ii, iv

- Pierce retention time calibration mixture (#88321, ThermoScientific)
- Pierce<sup>TM</sup> HeLa Protein Digest Standard (#88328, ThermoScientific)
- Heparan sulfate from porcine intestinal mucosa (HSPIM) (Celsus Laboratories, Inc.)
- Heparan sulfate from bovine kidney (HSBK) (SigmaAldrich)

## 2.2 Equipment

- Sonic dismembrator Model 100, FisherScientific
  - Vortex Bouxter S1P vortex MIXER, #S8223-1
  - Benchtop Centrifuge, VWR Galaxy mini
  - Pierce C18 spin columns (89870, Thermo-Fisher Scientific)
  - Microcon<sup>TM</sup> Centrifugal Filters for Protein and DNA Concentration: Ultrapure-10 Membrane (MRCPT010, MilliporeSigma)
  - Pierce Detergent Removal Spin Columns (Thermo-Fisher Scientific, 87777)
  - Incubator control for 37 °C
  - 22 R microfuge centrifuge, Beckmann Coulter
  - Centrifuge, Thermo IEC Micromax
  - Eppendorf thermomixer (1.5 mL, 37 °C, 60 °C)
  - Vacuum centrifugation (SPD1010 Speedvac system, Thermo Savant)
  - LC Systems – Agilent 1200 LC (Agilent Technologies), nanoAcuity UPLC (Waters Technology)
  - Mass Spectrometry systems – Agilent 6520 Q-TOF (Agilent Technologies), Q-Exactive HF mass spectrometer (Thermo-Fisher Scientific).
  - Columns
  - Superdex peptide (3.2/300 column, GE Healthcare Life Sciences)
    - Reversed phased C-18 analytical (BEH C18, 150  $\mu$ m  $\times$  100 mm) and trapping (180  $\mu$ m  $\times$  20 mm), Waters technology
    - GlycanPac AXH-1 (ThermoScientific) column (1.9  $\mu$ m, 0.3  $\times$  150 mm)

## 2.3 Software

- GlycReSoft software ([www.bumc.bu.edu/msr/glycresoft](http://www.bumc.bu.edu/msr/glycresoft))
  - Peaks Studio 8.5 or other proteomics database searching software
  - Qualitative analysis software (version B.06; Agilent Technologies).

## 3. Experimental design

### 3.1 Tissue lysis

Any free-floating or fresh frozen mammalian tissues can be used to perform the protocol. Once the tissue lysis is performed, the protein estimation of the lysis is required to use an equal amount of protein for different samples for further digestion steps.

### 3.2 Serial in-solution digestion

GAGs are released in-solution sequentially from equal amounts of tissue lysates using specific enzymes that cleave each GAG disaccharide, including hyaluronidase for HA disaccharides, chondroitinase ABC enzyme for CS disaccharides, and heparin lyase I, II, and III for HS disaccharides. After GAG removal, the peptides are released from the same sample using trypsin or trypsin + LysC. The removal of GAGs facilitates the identification of the proteins with higher peptide-coverage using conventional proteomics.<sup>16</sup> A FASP-type protocol is utilized to apply tissue lysate to MWCO (10 kDa, 0.5 mL), followed by serial application of specific enzymes to the sample on the filter, followed by overnight incubation (37 °C) and release of each GAG class (HA, CS, and HS) as a flow-through, followed by digestion of retained protein to release peptides.

### 3.3 Desalting for GAGs

There exist several orthogonal techniques for desalting of glycans including, size exclusion chromatography, strong anion exchange chromatography, and porous graphite carbon cleanup. We find size exclusion chromatography (SEC) as the most unbiased, efficient, and reproducible approach toward glycan desalting. The GAGs are cleaned using the SEC chromatography column (Superdex<sup>TM</sup> peptide PC 3.2/30, GE Healthcare), and they elute between 35–45 min at a UV absorbance of 232 nm.

### 3.4 C-18 cleanup peptides

The peptides are cleaned using ThermoScientific C-18 spin columns.

### 3.5 Data acquisition

A robust data acquisition workflow is equally important as a streamlined sample processing workflow. We analyze our GAG disaccharides on a negative ionization mode electrospray liquid chromatography (LC)-mass spectrometry (MS) system. The LC-MS conditions are optimized for higher recovery of

GAGs from LC, and appropriate tuning of MS source conditions to minimize in-source sulfate losses to identify highly sulfated disaccharide. Disaccharides are separated using a 1.9  $\mu\text{m}$ , 0.3  $\times$  150 mm GlycanPac AXH-1 (ThermoScientific) column mounted on an Agilent 1200 LC (Agilent Technologies, Santa Clara, CA). A 20 min isocratic method is used and a flow rate of 7  $\mu\text{L min}^{-1}$  (HS) and 5  $\mu\text{L min}^{-1}$  (HA and CS). Mass spectrometry analyses for GAGs is performed using an Agilent 6520 Q-TOF (Agilent Technologies, Santa Clara, CA) using electrospray ionization. A synthetic internal standard (800 fmol quantity of  $\Delta$ HexA2S-GlcNCoEt(6S) (Hd009, Iduron)) is added to all the samples before LC-MS analyses (Fig. S2, ESI<sup>†</sup>). We run a mixture of commercially available CS (Fig. 3) and HS (Fig. 4) standards disaccharides (Iduron) every day to ensure stable instrument performance. The criteria used in our laboratory for a satisfactory MS analysis of GAG disaccharides include a  $\leq 20\%$  coefficient of variation (CV), and  $\leq 30\%$  CV for CS and HS disaccharides, respectively. This is based on the observed CV values  $\pm 5\%$  that are observed in practice in our laboratory over different GAG experiments. A  $\leq 10\%$  variation in retention time is acceptable.

For proteomics, the instrument is calibrated every week in positive ion mode using positive mode calibration mixture (ThermoScientific), producing an intensity signal of  $4\text{--}5 \times 10^8$ , and  $\geq 15\%$  of MS/MS to MS signal for  $m/z$  524.3 under high-performance instrument conditions. A loading amount of 100 fmol of Pierce retention time calibration mixture (ThermoScientific) (Fig. S3, ESI<sup>†</sup>) and 50 ng of Pierce HeLa cell lysate (ThermoScientific) (Fig. S4, ESI<sup>†</sup>) are run day-to-day for instrument performance generating a detection signal of  $1.5\text{--}2 \times 10^9$ , and a  $2.5\text{--}3.5 \times 10^9$  under high-performance instrument conditions. A retention time variation of  $\leq 10\%$  is acceptable among various LC-MS/MS runs. The peptide samples are also spiked with a 50 fmol retention time calibration mixture as an internal standard prior to LC-MS analysis. Fig. S5 (ESI<sup>†</sup>) shows peptide spiked internal standard peptide ( $m/z$  493.7) to be consistent concerning signal intensity and retention time for various samples used in this protocol. The nano-LC-MS/MS separation of peptides is performed using a nanoAcquity UPLC (Waters Technology Corp.) and Q-Exactive HF mass spectrometer (Thermo-Fisher Scientific). Reversed phased C-18 analytical (BEH C18, 150  $\mu\text{m} \times 100$  mm) and trapping (180  $\mu\text{m} \times 20$  mm) columns from Waters technology are used with a 75 or 120 min method at a flow rate of 0.5  $\mu\text{L min}^{-1}$ . In a typical label-free proteomics experiment, we have a loading amount of  $\sim 100$  ng having a detection range of  $3\text{--}4 \times 10^9$ . We ensure that the total ion chromatograms (TICs) are within 2 fold for all the samples, and blanks or peptide retention time mixtures are run every 5–6 samples to identify any carry-over and run-to-run variability.

### 3.6 Data analysis

For glycomics, data are interpreted manually using the area under the curve for extracted ion chromatograms (EICs) from the raw LC-MS/MS data. The relative and absolute abundance of disaccharides are determined using standard curves. Student's *t*-tests are performed with two-tailed distribution using Microsoft Excel spreadsheets. For differentiating the

isoforms, EIC (MS/MS), the diagnostic ions as indicated in<sup>23</sup> for each CS and HS disaccharide isoform are extracted, and abundances are obtained from manual area calculation.

For proteomics, The raw LC-MS/MS data is run against a database using available commercial software, including PEAKS (Bioinformatics Solutions, Inc., Waterloo, ON, Canada) and/or proteome discoverer. For site-specific glycosylation analysis for enriched proteoglycans (and other glycoproteins), we use our in-house publically available GlycReSoft program.<sup>31,39</sup>

## 4. Procedure

**Samples:** We used various proteoglycan and protein standards and a commercially available mouse brain lysate (Table 2) to test the protocol and individual steps. All samples (except neurocan which was acquired for batch 1 only due to unavailability of sample for batch 2, and HS for syndecan-1 was acquired for only batch 1 as the sample was lost due to autosampler failure) were performed in two batches processed a week apart. Each sample was performed as two technical replicates for LC-MS/MS analysis. We used commercially available mouse brain lysate as a complex sample to test our protocol, but this protocol applies to any tissue. Fig. 2 outlines the protocol in a stepwise manner.

### 4.1 Tissue lysis

1. For tissue lysis, fresh or free-floating tissues ( $\sim 25$  mg) are lysed with a buffer (500  $\mu\text{l}$ ) (for each mg of tissue use about 15–20 times buffer volume) containing 50 mM Tris-HCl (pH = 7.5), 150 mM NaCl, 2 mM EDTA, protease inhibitor cocktail tablet, 1% SDS and 0.5% Triton X-100.

2. To homogenize tissue, perform ultra-sonication (sonic Dismembrator Model 100, Fisher Scientific) for 2 minutes with 20 s pulse and incubate for 30 min on ice followed by centrifugation at 12 000 rpm, 4 °C for 30 min.

3. The supernatant is transferred to separate tubes, and the protein concentration of each sample is determined using the Pierce BCA microassay (Thermo-Fisher Scientific).

**Pause point:** At this point, samples can be stored at  $-20$  °C before the next step or  $-80$  °C for extended storage.

**Caution:** Proteinase inhibitor cocktail tablets are only valid for one year from date of opening; it is essential to check the validity of the tablets, as an old tablet will not be effective and may cause protein degradation over time.

**Caution:** Make fresh lysis buffer and add proteinase tablets right before using the buffer.

### 4.2 In-solution digestion

4. Take an equal amount of lysis buffer, add at least 5 times acetone by volume, and leave overnight,  $-20$  °C. Next day, centrifuge the tube at 20 000  $\times g$ , 4 °C for 30 min. Discard the supernatant. Wash the protein pellet with 80% ACN/20% water, sonicate briefly, and centrifuge the tubes at 20 000  $\times g$ , 4 °C for 30 min. Discard the supernatant, and air dry the pellet, keeping the tubes upside down.

**Caution:** To ensure complete digestion of biomolecules on applying enzymes, effective removal of detergent is required. If the lysis buffer to be used contain a high concentration of detergent or is in bulk volumes, we recommend using Pierce Detergent Removal Spin Columns (Thermo-Fisher Scientific, 87777) for complete detergent removal before going to next step.

5. Take the protein pellet, add 5 mM Ammonium acetate, vortex, spin, and add 20 milliunits of hyaluronidase enzyme, vortex, spin, and incubate at 37 °C overnight on an Eppendorf mixer at 450 rpm.

6. Next day apply the solution to MWCO filters (Microcon™ Centrifugal Filters: Ultracel-10 Membrane, MRCPT010, MilliporeSigma), centrifuge at 14 000 × g, 4 °C for 20 minutes. Wash the filter with 200 µl of water, and centrifuge at 14 000 × g, 4 °C for 20 min. Repeat the step twice. Collect the flow-through; these are HA disaccharides.

**Caution:** Use of correct MWCO filters is essential to have an effective protein recovery. We recommend using 10 kDa filter and Microcon™ filter units with a horizontal membrane rather than Amicon filter units with vertical membrane design.

7. Put the filter from step 6 in a new Eppendorf tube and add Tris-HCl (pH = 8.0), making a final concentration of 20 mM, ammonium acetate (5 mM), chondroitinase ABC enzyme (20 milliunit), and vortex briefly, and incubate 37 °C overnight.

8. Next day, cool down samples and centrifuge the solution at 14 000 × g, 4 °C for 20 min. Wash the filter with 200 µl of water, and centrifuge at 14 000 × g, 4 °C for 20 min. Repeat the step twice. Collect the flow-through; these are CS disaccharides.

9. Put the filter from step 8 in a new Eppendorf tube, and add Tris-HCl (pH = 7.5) making a final concentration of 20 mM, ammonium acetate (5 mM), calcium chloride (5 mM), 20 milliunit each of heparin lyase I, II, and III, vortex briefly, and incubate 37 °C overnight.

10. Next day, cool down samples and centrifuge the solution at 14 000 × g, 4 °C for 20 min. Wash the filter with 200 µl of water, and centrifuge at 14 000 × g, 4 °C for 20 min. Collect the flow-through; these are HS disaccharides.

11. Put the filter on new Eppendorf, and add 200 µl 50 mM ammonium bicarbonate to buffer exchange, and centrifuge at 14 000 × g for 20 min at 4 °C. Repeat the step twice and discard the flow through.

12. Invert the filter in a new tube, centrifuge at 1000 g for 3 min at 4 °C to collect the protein. Wash the filter with 50 mM ammonium bicarbonate, and pool it with the collected protein solution.

13. To the protein sample, add DTT (5 mM), and incubate 60 °C for 30 min on an Eppendorf thermomixer at 450 rpm. Cool down the solution, and add IAA (10 mM), and incubate in the dark for 30 min at room temperature (RT).

14. Dilute the solution with 50 mM ammonium bicarbonate and add 1:30 trypsin-LysC (or trypsin), incubate at 37 °C, overnight on an Eppendorf mixer at 450 rpm. Next day stop the trypsinisation by adding 1% formic acid; these are the peptides.

15. All extracted disaccharides and peptides are dried under vacuum centrifugation (SPD1010 Speedvac system, Thermo Savant).

Pause point: Disaccharides and peptides can be stored at -20 °C before further desalting and cleanup.

### 4.3 Desalting/cleanup

16. Resuspend the dried disaccharides in 10 µL of water and inject onto the Superdex Peptide (3.2/300) size exclusion column, using the mobile phase (25 mM ammonium acetate, 5% acetonitrile) at a flow rate of 0.04 mL min<sup>-1</sup>. HA, CS, and HS disaccharides are collected between 35–45 min. The clean HA, CS, and HS disaccharides are dried by vacuum centrifugation.

17. For peptides:

- Wash the C-18 spin columns with 200 µl of 50% ACN/50% H<sub>2</sub>O, centrifuge at 1500 × g for 1 minute.

- Equilibrate columns with 200 µl of 2% ACN/98% H<sub>2</sub>O/0.1% TFA, centrifuge at 1500 × g for 1 minute. Repeat twice.

- Reconstitute sample in 100 µl of 2% ACN/98% H<sub>2</sub>O/0.1% TFA, apply to the C-18 column, centrifuge at 1500 × g for 1 min.

Note: the flow-through should be reapplied to the spin column and centrifuged, repeating a total of two times to ensure complete peptide binding to C-18. Do not discard the flowthrough, dry, and store at -20 °C.

- Wash the filter with 200 µl of 2% ACN/98% H<sub>2</sub>O/0.1% TFA, centrifuge at 1500 × g for 1 min. Repeat thrice.

- Elute the peptides using 30 µl of 60% ACN/40% H<sub>2</sub>O/0.1% TFA, centrifuge at 1500 × g for 1 min. Repeat twice.

- Dry the clean peptides under vacuum centrifugation.

### 4.4 Data acquisition

18. LC-MS/MS analysis for HA, CS, and HS disaccharides GAG disaccharides are analyzed using negative mode electrospray ionization on a 6520 Q-TOF (Agilent technologies). They are separated using a 1.9 µm, 0.3 × 150 mm GlycanPac AXH-1 (ThermoScientific) column mounted on an Agilent 1200 LC (Agilent Technologies, Santa Clara, CA). A 20 min isocratic method is used (85% B) and a flow rate of 5 µL min<sup>-1</sup> (HA, and CS) and 7 µL min<sup>-1</sup> (HS). Solvent A is 50 mM ammonium formate pH 4.4 in 10% ACN, and solvent B is 95% ACN/5% water. Samples are constituted in 85% B, and an 800 fmol quantity of ΔHexA2S-GlcNCoEt(6S) (Iduron) is added to all the samples as an internal standard before LC-MS analyses. The targeted tandem-MS analysis is performed to differentiate between HS and CS disaccharide isoforms (Fig. 2 and 3) with a collisional induced dissociation (CID). Fixed collision energy of 20 is used. The targeted list for CS is CS was *m/z* 458 (z = 1) and HS is *m/z* 458 (charge; z = 1), and *m/z* 496 (z = 1). The relative and absolute abundance were determined using standard curves as previously described.<sup>5,24,25</sup>

### 19. Nano-LC-MS/MS analysis peptides

Nano-LC-MS/MS analysis is conducted by a Q-Exactive HF mass spectrometer (Thermo-Fisher Scientific) equipped with a nano ultra-performance liquid chromatography (UPLC) (Waters Corporation) peptides are trapped on a trapping (180 µm × 20 mm) column and separated on a reversed phased C-18 analytical (BEH C18, 150 µm × 100 mm) column (Waters Corporation). We load 1 µL onto the column, and separation is achieved using a 75 min (alternatively 120 min gradient can be used) gradient of 2 to 98% acetonitrile in 0.1% FA at a flow rate of ~500 nL min<sup>-1</sup>. Data-dependent acquisition tandem

MS is acquired in the positive ionization mode for the top 20 most abundant precursor ions. The scan sequence begins with an MS1 spectrum (Orbitrap; resolution 60 000; mass range 300–2000  $m/z$ ; automatic gain control (AGC) target  $1 \times 10^6$ ; maximum injection time 100 ms). MS2 analysis consists of higher energy collisional dissociation (Orbitrap; resolution 15 000; AGC  $1 \times 10^5$ ; normalized collision energy (NCE) 30; maximum injection time 100 ms, dynamic exclusion time of 8 s).

#### 4.5 Data analysis

##### 20. Glycomics data analysis

Glycomics data analysis is performed manually by extracting extracted ion chromatograms (EICs) for HA, CS, and HS dis-

accharides for each sample from the raw LC-MS/MS data using qualitative analysis software (version B.06; Agilent Technologies). The obtained abundances for each disaccharide are first normalized to a spiked internal control and then further normalized to a standard curve to obtain an absolute and relative abundance of HS or CS disaccharides (fmol) in a Microsoft Excel spreadsheet. For differentiating the isoforms, EIC (MS/MS) for diagnostic ions as indicated in ref. 23 for each CS and HS disaccharide isoform are extracted, and abundances are obtained from manual area calculation.

##### 21. Proteomics data analysis

The raw LC-MS/MS data are converted into mzXML format using ProteoWizard msConvert.<sup>40</sup> The data are searched using PeaksDB and PeaksPTM using Peaks Studio version 8.5 (Bioinformatics Solutions, Inc., Waterloo, ON, Canada) against the Uniprot/Swissprot database for appropriate species with a 1% false discovery rate and at least two unique peptides. A 10 ppm error tolerance for the precursor (MS1) and 0.02 Da mass error tolerance for fragment ions (MS2) are specified. A maximum of 3 missed cleavages per peptide is allowed for the database search, permitting non-tryptic

#### 4.6 Tips for troubleshooting are provided in Table 3

Table 3 Tips for troubleshooting

Step	Problem	Possible reason	Solution
Step 18	Absence of GAG disaccharides	<ul style="list-style-type: none"> <li>The enzyme was not active or present in sufficient quantity</li> <li>Detergent is still present in the samples that interfered with enzyme activity</li> </ul>	<ul style="list-style-type: none"> <li>✓ Check for enzyme activity</li> <li>✓ Check for enzyme validity by the supplier</li> <li>✓ To ensure complete detergent removal, we recommend using detergent removal spin columns (ThermoScientific)</li> <li>✓ Tune source for fragile tuning and sulfate loss</li> </ul>
Step 18	Absence of triply sulfated forms	<ul style="list-style-type: none"> <li>MS Source conditions are not optimal and in-source sulfate loss</li> </ul>	<ul style="list-style-type: none"> <li>✓ Tune source for fragile tuning and sulfate loss</li> </ul>
Step 19	Low peptide/protein identification	<ul style="list-style-type: none"> <li>Peptide loss</li> <li>Protein loss</li> </ul>	<ul style="list-style-type: none"> <li>✓ Check flow-through from step 17, possible loss of peptides</li> <li>✓ Make sure to use correct MWCO filters with horizontal membranes with at least 10 kDa cut off</li> <li>✓ Ensure the proteinase inhibitor used for lysis buffer was valid and active to avoid overtime degradation of the protein</li> <li>✓ Check the number of tandem spectra acquired and the proportion of PSM matched. The expected ration should be 30%</li> <li>✓ For MS<sup>2</sup> sensitivity: Check the quality of ms2 spectra in peptide, retention time calibration mixture</li> <li>✓ Check for <math>m/z</math> 524.3 in the positive-mode calibration mixture; the intensity of MS2 peaks should be 15% higher than MS1</li> </ul>
Step 19	Observe high TIC but a low number of proteins identified	<ul style="list-style-type: none"> <li>Presence of lipids contaminant from tissue</li> <li>Loss in MS2 sensitivity</li> </ul>	

## 5. Results & discussion

We describe herein a robust and streamlined protocol (Fig. 2) that utilizes the FASP type approach of digesting biomolecules on a MWCO filter and extracting the released biomolecules as a flowthrough. We used a commercial mouse brain lysate as a complex sample and several standard proteoglycan and proteins for testing each and/or several steps of the protocol, as shown in Table 2. We performed experiments in two different batches one week apart from each other to test the reproducibility of the protocol, except for neurocan and HS of syndecan-1, which were acquired only for batch 1. We were able to identify 1 HA, 6 CS, and 8 HS unsaturated disaccharides from the standard proteoglycans and complex sample. In the complex sample, HS D2S6 was absent or present below the detectable limit. In addition, we observed 3 CS saturated disaccharides (U0a0, U0a4/U0a6) for standard proteins, while only 2 (U0a4/U0a6) were observed for the complex sample. For HS, 3 saturated disaccharides were observed (U0A0, U0A6/U2A0) for standards, while only 1 (U0A0) was observed for the complex sample. The ion abundance counts (normalized

Table 4 The % coefficient of variation (% CV) of each disaccharide (HA, CS, and HS) observed for standards and lysate samples for batch 01 vs. 02

Samples	% coefficient of variation (% CV)				
	D0a0				
<b>HA disaccharides</b>					
Hyaluronic acid-batch 01 vs. 02	7				
Lysate-batch 01 vs. 02	14				
Samples	% coefficient of variation (% CV)				
	D0a0	D0a4/D0a6	D0a10/D2a4/D2a6	U0a0	U0a4/U0a6/U2a0
<b>CS disaccharides</b>

Lysate-batch 01 vs. 02	22	16	4	14	16
	D2S6				
	U0A0	UOA6/U2A0			

(to internal standard *m/z* 552) area under the curve (AUC)  $\pm$  standard deviation (SD))) are shown in Table S1 (ESI $\dagger$ ), and coefficient of variation (% CV) for each disaccharide for all samples are shown in Table 4. The CVs for the two batches were within our specified criteria of  $\leq 20\%$  for CS, and  $\leq 30\%$  CV for HS disaccharides, illustrating a similar recovery of GAGs in the two batches.

For proteomics, syndecan and neurocan were observed with 67%, and 64% coverage, respectively, while Aggrecan was observed with 27% coverage (Table 5A and Supplemental file S1, ESI $\dagger$ ). Aggrecan contains approximately 90 CS chains based on the total masses of core protein, CS, and the average mass of CS chains. $^{26}$  With no CHABC treatment and proteolysis with

trypsin + LysC, we observed 17% sequence coverage of aggrecan (Supplemental file S1, ESI $\dagger$ ). Thus, the removal of CS chains assists in better identification of aggrecan. To increase peptide coverage for aggrecan, Glu-C digestion could be performed, followed by trypsin + Lys-C digestion as trypsin as the only protease produces extended region glycopeptides that are too large for analysis using HCD LC-tandem MS. $^{16}$  A number of post-translational modifications (PTMs) for aggrecan, neurocan, and syndecan were observed including, *O*-glycosylation (HexNAc & HexNAcHex) on serine and threonine as identified by peaks PTM analysis (Table 5A and Fig. S6, ESI $\dagger$ ).

For mouse brain tissue lysate, we observed 1449 and 1496 proteins with 1 unique peptide, and 747 and 773 proteins with

Table 5 (A) Coverage, total, and unique peptides for standard proteins and proteoglycans as observed by LC-MS/MS analysis after serial in-solution digestion. (B) Total proteins for both unique peptides 1 and 2, and coverage of proteoglycan and other ECM related proteins as observed for complex mixtures- mouse brain tissue lysate)

(A) Standard protein/ proteoglycans	Coverage (total, unique peptides)-batch 1	Coverage (total, unique peptides)-batch 2	PTMs
Aggrecan	27% (162, 158)	28% (188, 184)	Carbamidomethylation; hydroxyproline; ubiquitination deamidation; K-methoxy; HLys; HexNAcHex; HexNAc
Syndecan	67% (139, 139)	—	HexNAc, HexNAcHex hydroxyproline; deamidation; phosphorylation, K-methoxy; ubiquitination
Neurocan	64% (383, 371)	—	Carbamidomethylation; hydroxyproline, phosphorylation, HexNAcHex; HexNAc deamidation N; ubiquitination, HLys-Hex; HLys-Hex-Hex
AGP	65% (53, 41)	60% (53, 39)	Carbamidomethylation; hydroxyproline, deamidation; K-methoxy, HLys; ubiquitination, HexNAc Y-NO <sub>2</sub> , K-methoxy
(B) Complex mixture	Total proteins with unique peptide 1	Total proteins with unique peptide 2	PG and ECM related proteins observed coverage (total, unique peptide)
Mouse brain lysate	1449-batch 1 1496-batch 2	747-batch 1 773-batch 2	Versican 0% (1, 1) Neurocan 1% (1, 1) Brevican 4% (3, 3) Tenascin-R 5% (6, 6) Disintegrin and metalloproteinase domain-containing protein 22 2% (1, 1)

**Table 6** Average normalized area (normalized to total ion chromatogram (TIC)) for batch 01 and 02  $\pm$  standard deviation and % relative standard deviation (% RSD) for the standard proteins

Protein	Normalized area batch 01	Normalized area batch 02	Average normalized area $\pm$ standard deviation	Relative standard deviation (%)
Syndecan-1	$4.10 \times 10^9$	$4.00 \times 10^9$	$4.05 \times 10^9 \pm 6.85 \times 10^7$	2
AGP	$2.09 \times 10^9$	$2.37 \times 10^9$	$2.23 \times 10^9 \pm 1.96 \times 10^8$	9
Aggrecan	$1.37 \times 10^{10}$	$1.35 \times 10^{10}$	$1.26 \times 10^{10} \pm 1.74 \times 10^8$	1
Neurocan <sup>a</sup>	$5.61 \times 10^{10}^a$	$5.02 \times 10^{10}^a$	$5.32 \times 10^{10} \pm 4.16 \times 10^9^a$	8 <sup>a</sup>

<sup>a</sup> For the two replicates in batch 01.

2 unique peptides for batch 1 and 2, respectively. The average normalized area (normalized to total ion chromatogram (TICs)) with relative standard deviations (RSDs) between the two batches for standard proteins are shown in Table 6 (For the complete list of average normalized area and RSDs for lysate and standard proteins see Supplemental file S2, ESI<sup>†</sup>). A number of PGs and ECM related proteins were observed but with low coverage (Table 5B and Supplemental file S1, ESI<sup>†</sup>). Thus, to achieve a complete picture of ECM and proteoglycans in complex samples, an enrichment step needs to be incorporated such as using anion-exchange (SAX) chromatography followed by serial in-solution digestion as presented here and sequential proteolysis using a combination of trypsin-LysC/GluC/chymotrypsin prior to LC-MS/MS to attain more in-depth PG sequence coverage. To study proteins displaying specific PTMs enrichment is usually necessary to increase the relative analyte abundance, such as enrichment of PGs using SAX,<sup>34,41</sup> and enrichment of glyco-peptides/-proteins using lectin affinity chromatography, hydrazide chemistry,<sup>42</sup> and hydrophilic interaction liquid chromatography (HILIC)<sup>43,44</sup> have been extensively used by experts in the field of glycoscience. We plan to incorporate the enrichment step in the presented protocol for more targeted workup and in-depth PG analysis in the future. When we performed the serial in-solution protocol on a human brain tissue lysed in-house rather than a commercial mouse brain, we observed 1297 proteins with 1 unique peptide, and 782 proteins with 2 unique peptides and a number of ECM related proteins and proteoglycans were observed with high coverage (Supplemental file S3, ESI<sup>†</sup>). This implies that the low coverage of PG or ECM proteins in the commercial mouse brain lysate could be sample-related.

In conclusion, we present a streamlined protocol to perform integrated glycomics and proteomics on tissue samples. This protocol could be utilized for simultaneous processing of 24 samples at a given time, making it efficient and high-throughput despite a 5 day workup procedure. The end goal is to establish a robust platform for identification and characterization of GAG compositions and PG and other ECM related molecules specifically in the brain that play crucial roles in various neurological processes and understand their role in underlying molecular mechanisms in neuropsychiatric disorder.

## Abbreviations

FASP	Filter-aided sample preparation
GAGs	Glycosaminoglycans

PGs	Proteoglycans
ECM	Extracellular matrix
HS	Heparan sulfate
HA	Hyaluronic acid/hyaluronan
CS	Chondroitin sulfate
MWCO	Molecular weight cut off
TIC	Total ion chromatogram
EIC	Extracted ion chromatogram
LC-MS/MS	Liquid chromatography-tandem mass spectrometry
