Ruthenium-catalysed cyclisation reactions of 1,11-dien-6-yne s leading to biinden es[†]

Takanori Matsuda * and Naoto Yonekubo

1,2-Bis(2-allylphenyl)ethynes undergo cycloisomerisation reactions in the presence of $\text{Cp}^*\text{Ru}(\text{ii})$ catalysts to produce 2,2'-dimethyl-3H,3'H-1,1'-biinden es. On the other hand, tandem ring-closing metathesis of 1,2-bis(2-allylphenyl)ethynes using the Hoveyda–Grubbs 2nd generation catalyst led to the formation of 2,2'-unsubstituted biinden es. Various symmetrical and unsymmetrical bicyclic dienes were prepared by these ruthenium-based cyclisation methods.

Introduction

3H,3'H-1,1'-Biinden es have previously been prepared by the oxidative homocouplings of (1H-inden-1-yl)lithiums to yield diastereomeric mixtures of 1H,1'H-1,1'-biinden es, followed by base-promoted double bond isomerisation.¹ There are fewer than fifty known biinden es, and some of them have been used as ligands for transition metals,² while a biindene-derived diol has been used as a chiral ligand in the titanium(IV)-catalysed enantioselective additions of diethylzinc to aldehydes.³

Transition-metal-catalysed cycloisomerisation reactions of enynes are powerful tools for the synthesis of various carbocyclic and heterocyclic compounds.⁴ This method allows for the rapid atom-economical construction of a complex cyclic structure from a linear substrate. The ring-closing metathesis (RCM) of dienes and enynes revolutionised the way in which cycloalkenes are assembled, and has been extremely useful in modern organic synthesis.⁵ Herein, we report that 1,11-dien-6-yne s can undergo both cycloisomerisation and tandem RCM reactions catalysed by ruthenium complexes. Notably, these reactions are used to prepare 1,1'-biinden es from 1,2-bis(2-allylphenyl)ethynes.

Results and discussion

When 1,2-bis(2-allylphenyl)ethyne (**1a**)⁶ was heated at 60 °C in EtOH in the presence of 5 mol% $\text{CpRuCl}(\text{PPh}_3)_2$ for 24 h, it cycloisomerised to afford 2,2'-dimethyl-3H,3'H-1,1'-biindene (**2a**) in 21% yield (Table 1, entry 1). The use of $\text{Cp}^*\text{RuCl}(\text{PPh}_3)_2$ improved the yield of **2a** to 45% (entry 2), while the reaction in

the presence of $\text{Cp}^*\text{RuCl}(\text{cod})$ afforded **2a** in 34% yield (entry 3). The use of a cationic ruthenium catalyst generated *in situ* from $\text{Cp}^*\text{RuCl}(\text{cod})$ and NaPF_6 gave **2a** in 55% yield (entry 4); indeed, preformed cationic $[\text{Cp}^*\text{Ru}(\text{MeCN})_3]\text{PF}_6$ exhibited comparable activity (entry 5). The effect of the phosphine ligand was next examined; **2a** was formed in 38% yield when the $\text{Cp}^*\text{RuCl}(\text{cod})$ -BINAP catalyst system was used (entry 6); however, use of $\text{P}(\text{C}_6\text{F}_5)_3$ increased the yield of **2a** to 61%, together with a 24% yield of the [2 + 2 + 2] cycloadduct **3a** (entry 7).^{7,8} The reaction performed in MeOH in the presence of $\text{Cp}^*\text{RuCl}(\text{cod})$ - $\text{P}(\text{C}_6\text{F}_5)_3$ furnished **2a** in 85% isolated yield without any noticeable amount of **3a** (entry 8). A similar result was obtained when the reaction was performed at 40 °C (entry 9). Interestingly, the reaction delivered cycloadduct **3a** as the major product when performed in *i*-PrOH (entries 10 and 11).⁹

With the optimised reaction conditions in hand, various diallyl diphenylacetylenes **1b-l** bearing substituents on their benzene rings were subjected to the ruthenium-catalysed cycloisomerisation conditions (Table 2). The reaction of 1,2-bis(2-allyl-4-methylphenyl)ethyne (**1b**) afforded tetramethylbiindene **2b** in 67% yield (entry 1), whereas symmetrical dienynes **1c** and **1d** bearing methyl or methoxy groups at the 5 positions of their benzene rings afforded **2c** and **2d**, respectively, in good yields (entries 2 and 3). In contrast, the reactions of chloro- and trifluoromethyl-substituted dienynes **1e** and **1f** formed the [2 + 2 + 2] cycloadducts **3** as major products under the standard conditions (**1e**: **2e** 24% + **3e** 41%; **1f**: **3f** 87%). The cycloisomerisation products from **1e** and **1f** were obtained as the major products in yields of 44% and 29%, respectively, when the reaction was performed with $[\text{Cp}^*\text{Ru}(\text{MeCN})_3]\text{PF}_6$ (entries 4 and 5). The naphthalene derivative **1g** was also converted into the corresponding product **2g** (entry 6), while unsymmetrically substituted biinden es **2h-l** were similarly prepared by cycloisomerising dienynes **1h-l** (entries 7–11).

The cycloisomerisation conditions were successfully applied to dienye **1m** devoid of *o*-phenylene tethers, which

^a Reaction conditions: 1a (0.050 mmol), ruthenium catalyst (2.5 μmol, 5 mol%), ligand (Ru : P = 1 : 2), solvent (0.5 mL, 0.1 M). ^b Isolated yield.

led to the formation of 1,1'-bicyclopentene **2m** in 82% yield in the presence of [Cp^{*}Ru(MeCN)₃]PF₆ (Scheme 1, (a)). The alternative cycloisomerisation product **4m** was obtained in 55% yield when **1m** was reacted at 0 °C (Scheme 1, (b)).^{10,11} Heating **4m** in the presence of the ruthenium catalyst gave **2m** in 49% yield, but no isomerisation was observed in the absence of the ruthenium catalyst. Based on these results as well as previous studies, we conclude that 2-methylene-1,1'-bi(cyclopentylidene) **4m** is the initial cycloisomerisation product, and that **4m** is also catalytically isomerised to **2m** by the ruthenium catalyst.

Two possible reaction pathways can be proposed for the ruthenium-catalysed cycloisomerisation of 1,11-dien-6-yne **1** (Scheme 2). Path (a) involves the formation of a hydroruthenium species from the catalyst and MeOH,¹² a Markovnikov hydroruthenation to the C=C bond of **1** to form **A**, consecutive carboruthenation (through **B** to **C**), β-hydride elimination that releases **4**, and the final double bond isomerisation of **4** to afford product **2**. On the other hand, in path (b), diyne **1** first undergoes oxidative cyclisation on ruthenium to generate the ruthenacyclopentene species **D**. The unreacted alkene moiety in **D** then inserts into the Ru-C(sp²) bond to give the ruthenacycloheptene intermediate **E**. Subsequent β-hydride elimination (to form **F**) followed by reductive elimination yields **4**, which then isomerises to **2** catalysed by a hydroruthenium species. Alternatively, β-hydride elimination from **D** generates alkenylruthenium hydride **G**, which also leads to **4** through intramolecular carboruthenation (to **F**) or hydroruthenation (to **H**). Reductive elimination from intermediate **E** is possible, which gives rise to the [2 + 2 + 2] cycloadduct **3**.

Dienyne **1n** or **1o**, in which one allyl group is replaced with a crotyl or a methallyl group, was found to be unreact-

tive toward cycloisomerisation, which reveals that the reaction is limited to diynes with unsubstituted C=C double bonds (Chart 1). Moreover, 1,2-bis[2-(vinyloxy)phenyl] ethyne (**1p**) also failed to react, and a complex mixture of products was obtained when unsymmetrical diyne **1q**, bearing malonate and *o*-phenylene tethers, was reacted.¹³

We have been interested in the catalytic syntheses of silole derivatives¹⁴ and the cycloisomerisation of bis-silicon-bridged **1r** was envisaged as a method for the synthesis of a bi(1-siladene).¹⁵ However, the reaction of **1r** under conditions similar to those described above led to a totally different outcome: 1,1',2,2'-tetrahydro-4,4'-bi(1-silanaphthalene) **5** was obtained in 43% yield as the sole product after full conversion of **1r** (Scheme 3). The silanaphthalene **5** may have formed through a stitching reaction mediated by a hydroruthenium species in a manner analogous to the path (a) in Scheme 2, but with initial anti-Markovnikov hydroruthenation.

Tandem ring-closing metathesis (RCM) of 1,11-dien-6-yne that form 1,1'-bicyclopentene derivatives has previously been studied,¹⁶ but those of 1,2-bis(2-allylphenyl) ethynes have, to the best of our knowledge, never been examined. If allowed, this reaction provides a route to 3,3'-H-1,1'-biindenes that lack substituents at their 2 and 2' positions, which is complementary to the cycloisomerisation of **1**. Tandem RCM of **1a** in the presence of the Hoveyda-Grubbs 2nd generation catalyst at 100 °C in toluene (0.1 M) afforded the desired biindene **6a** in 60% yield (Table 3, entry 1). A lower concentration of **1a** resulted in an improved yield of **6a**, and 0.02 M was found to be optimal for the present reaction (entries 2 and 3). Other Grubbs catalysts were not suitable for this transformation (entries 4 and 5), while the reaction with 3 mol% catalyst gave a

trical (**1h–l**) diynes were converted through tandem RCM into biindenenes **6b–l** in yields ranging from 63% to 96%. Furthermore, diynes **1o–q**, which failed to cycloisomerise, also reacted to afford the corresponding metathesis products **4o–q**, respectively, in good yields. However, the attempted tandem RCM of the bis-silicon-bridged **1r** resulted in no conversion under various metathesis conditions.

Conclusions

In conclusion, we developed ruthenium-catalysed cycloisomerisation and tandem-RCM methods for the synthesis of bicyclic conjugated dienes, in which two rings (cycloalkenes) are constructed. Cycloisomerisation of 1,11-dien-6-yne afforded 2,2'-dimethyl-[1,1'-bi(cyclopentene)] derivatives catalysed by Cp^*Ru . On the other hand, 2,2'-unsubstituted bicyclopentenes were prepared through the tandem RCM of 1,11-dien-6-yne with the Hoveyda–Grubbs catalyst.¹⁷
