E,Z-Selectivity in the reductive cross-coupling of two benzaldehydes to stilbenes under substrate control†

Nicolas D'Imperio, Anna I. Arkhypchuk and Sascha Ott *

Unsymmetrical *E*- and *Z*-stilbenes can be synthesized from two differently substituted benzaldehydes in a MesP(TMS)Li-promoted reductive coupling sequence. Depending on the order of addition of the two coupling partners, the same olefin can be produced in either *E*- or *Z*-enriched form under identical reaction conditions. A systematic study of the correlation between the stereochemical outcome of the reaction and the substitution pattern at the two aldehydes is presented. The results can be used as guidelines to predict the product stereochemistry.

Introduction

The stereochemistry of carbon–carbon double bonds is of crucial importance for the chemical properties of alkenes^{1–4} and their function in nature⁵ and commodity chemicals.^{6,7} Thus, developing methods to selectively access either the *E*- or *Z*-isomer has been, and still is, at the heart of organic chemistry. A plethora of protocols for synthesizing olefins is available,^{8,9} among which the most widely used are the Wittig,^{10,11} Horner–Wadsworth–Emmons (HWE),¹² Peterson,¹³ olefin metathesis^{14,15} and cross-coupling reactions.^{16,17} In classical carbonyl olefinations mediated by phosphorus compounds,⁹ namely the Wittig,¹⁸ Horner–Wittig¹⁹ and HWE²⁰ reactions, the factors that influence the *E*- and *Z*-stereoselectivity are well understood and can be controlled, for example, by the nature of the phosphorus reagent, the base or the solvent.^{21–26} It should be pointed out that in almost all cases the stereochemical outcome of the reaction is determined by the reaction conditions or the type of olefinating reagent, and is usually not influenced by the nature of the aldehyde substrates. To the best of our knowledge, the only example in which a substituent at the aldehyde has been reported to influence the *E*-*Z* ratio of a Wittig olefination is in the case of benzaldehydes with heteroatoms such as halides or ethers in the *ortho*-position. This so-called “*ortho*-effect”^{27,28} can be exploited to synthesize enriched *Z*-stilbenes, as shown by Gilheany and co-workers.^{29–31} As shown in Scheme 1a, the reaction gives rise to higher proportions of *Z*-alkene when the

aldehyde has an *ortho*-substituent. In contrast, an *ortho*-substituent on the phosphonium salt has no such effect, and the thermodynamically more stable *E*-stilbene is formed (Scheme 1b). From a mechanistic viewpoint, the *Z*-directing effect of the *ortho*-substituent arises from a secondary bonding interaction between the phosphorus and the *ortho*-heteroatom during the transition state.^{29,31}

In recent years, we have been interested in developing new phosphorus mediated cross-coupling reactions of carbonyl compounds to olefins.^{32–35} In one of our latest work, we have been able to couple two different benzaldehydes selectively to unsymmetrical 1,2-disubstituted stilbenes *via* phosphalkene (2) and phosphinate (3) intermediates (Scheme 2).³⁴ In this one-pot reaction, a first benzaldehyde **A** is converted to a phosphalkene **2** which proceeds under Umpolung of the carbonyl-carbon. Subsequent activation of the phosphalkene provides phosphinates **3** which react with the second aldehyde **B** to form an unsymmetrical stilbene. In contrast to the McMurry chemistry that is traditionally used for the reductive coupling

Scheme 2 One-pot phosphorus mediated cross-coupling of two different benzaldehydes to *E*- and *Z*-olefins.³⁴

of carbonyl compounds to alkenes, the reaction proceeds by an ionic mechanism, and allows the controlled preparation of unsymmetrical alkenes owing to the successive addition of the two aldehydes to the reaction. While developing this method, an interesting trend in the *E*-*Z* ratio of the formed products attracted our attention. Herein, we report on a systematic study of how the stereochemical outcome of the cross-coupling reaction can be altered simply by choosing the order of addition of the two benzaldehyde substrates. As will be shown by various examples, the reactions proceed to a large extent under substrate control, with electronic effects as well as the presence of *ortho*-substituents determining the product stereochemistry.

Results and discussion

The influence of the aldehydes' substituents on the stereochemical outcome of the reaction was tested and the existence of two separate effects in the coupling procedure was noticed. A first effect is of electronic nature, and best studied when the aldehydes are substituted in the *para*-position; a second one can be observed in the reaction of *ortho*-substituted benzaldehydes. Both effects will be discussed separately first, and then in combination. To understand the role that the electronic nature of the two benzaldehyde substrates has on the *E*-*Z* ratio of the newly formed double bond, a series of reactions between *para*-substituted benzaldehydes was investigated. The results of the study are summarized in Table 1.

As shown in Table 1, entries 1–3, the electronic nature of the *para*-substituent on aldehyde **B** does not influence the outcome of the reaction to a great extent, as all three reactions predominantly form *E*-enriched products. A different picture emerges from a comparison between entries 4–6. With an electron deficient aldehyde **A** (entry 4, X = Br), the reaction forms exclusively the *E*-isomer. This selectivity is however compromised by moving to more and more electron-rich aldehydes **A**. Changing the X group from the electron-withdrawing (EWG) bromide to the electron-donating (EDG) methyl moiety (entry 5) leads to a 1 : 1 mixture of *E*- and *Z*-stilbenes, and in the case of the most electron-rich *para*-methoxy-substituted aldehyde **A** (entry 6), the *Z*-isomer is observed in a roughly 2 : 1 ratio. Entries 7–10 describe the results of homo-coupling experiments which in essence further corroborate the trends observed in entries 1–6. When X = Y = Br (entry 7), the reaction is, as expected, *E*-selective as a result of the EWG in aldehyde **A**. Alternative EWGs on aldehyde **A** such as a nitro-group have

Table 1 *E*- and *Z*-Stilbenes from the coupling of two *para*-substituted benzaldehydes. X = H, Br, Me, and OMe on aldehyde **A**. Y = H, Br, Me, and OMe on aldehyde **B**. Reaction conditions as in Scheme 2. *E*-*Z* ratios are determined from isolated stilbenes

Entry	Aldehyde A	Aldehyde B	Isolated yield, %	<i>E</i> - <i>Z</i> ratio
1	H	Br	46	70/30
2	H	Me	52	75/25
3	H	OMe	75	87/13
4	Br	H	45	100/0
5	Me	H	39	52/48
6	OMe	H	57	38/62
7	Br	Br	58	100/0
8	H	H	52	75/25
9	Me	Me	44	69/31
10	OMe	OMe	40	50/50
11	Br	Me	32	100/0
12	Me	Br	74	49/51
13	Br	OMe	35	100/0
14	OMe	Br	48	30/70

previously been shown to also give exclusively the *E*-isomer.³⁴ However, with increasing electron-donating character of the *para*-substituent in aldehyde **A**, higher percentages of *Z*-isomers are formed.

Entries 11–14 illustrate the significance of the effects that are described herein, and ways to exploit them for the preferential preparation of *E*- or *Z*-isomers. Reactions 11, 12, 13, 14 employ the same starting materials under identical conditions, but exhibit a dramatic difference in *E*-*Z* selectivity. When aldehyde **A** carries an EWG (X = Br, entries 11 and 13), only the *E*-olefins are formed. Changing the order of addition turns the substrates with an EDG (X = Me (entry 12) and X = OMe (entry 14)) into aldehyde **A**, leading to the opposite preferential stereoselectivity with the *Z*-isomers becoming the predominant forms.

Summarizing the results from Table 1, it is clear that the electronic nature of aldehyde **A** has a great influence on the alkene stereochemistry, while that of aldehyde **B** is negligible. *E*-Alkenes are exclusively formed when aldehyde **A** is electron-deficient, while *Z*-alkenes become the major product for elec-

tron-rich aldehydes **A**. This trend can be observed in a study where aldehyde **B** is kept constant (for this study a *para*-Br) and aldehyde **A** varied. In entry 7, only the *E*-isomer is formed due to the use of an EWG substituent on aldehyde **A**. With electron-neutral benzaldehyde as the first coupling partner (entry 1), 30% of *Z*-isomer is generated. When a fairly good EDG like *p*-CH₃ (entry 12) is used, the reaction forms *E*- and *Z*-isomers in an almost 1 : 1 ratio. Ultimately, with the stronger EDG *p*-OMe (entry 14), the *E/Z* ratio is 30/70. Plotting the proportion of *Z*-selectivity versus the Hammett parameter of the substituents on aldehyde **A** yields a straight line (see ESI, Fig. S33†), suggesting that it may be possible to predict the product stereochemistry for new combinations of reactants in the future.

The results presented in Table 1 nicely illustrate the strength of this procedure: the same olefin can be synthesized in higher *E*- or *Z*-form only depending on the order of addition of the two aldehydes during the sequence. The opportunities that the method offers are greater the higher the electronic difference between the two benzaldehydes.

Following the study on electronic effects, and inspired by the *Z*-directing *ortho*-effect described by Gilheany and co-workers,^{29,31} a series of experiments with different *ortho*-substituted benzaldehydes were performed (Table 2).

Entries 1–3 describe reactions where the *ortho*-substitution is on aldehyde **B**. In all such cases, *Z*-olefins are formed as the major products. No influence from the electronic nature of the *Y* group on aldehyde **B** is noticeable, and the *E–Z* ratio is similar in all three cases. Entries 4–6 show examples in which the *ortho*-substitution is on aldehyde **A**. The stereochemical outcome is opposite compared to that in entries 1–3, and the *E*-isomer is the predominant form. When *X* = Br (entry 4), the reaction is 100% *E*-selective while with EDG moieties (entries 5 and 6), a certain percentage of *Z*-isomer is formed. These

trends thus mirror the findings from Table 1, and no *ortho*-effect can be established for aldehydes **A**.

Entries 7–9 show examples of homocoupling reactions between *ortho*-substituted benzaldehydes. When *X* = *Y* = Br (entry 7), the reaction forms preferentially the *E*-isomer. This result has to be viewed in context of entries 1 and 4, in which the *ortho*-bromide is *Z*-directing for aldehyde **B** and *E*-directing for aldehyde **A**. The two effects are thus working in opposite directions, explaining the observed reaction outcome. With EDGs (entries 8 and 9), the situation changes, and the *ortho*-substituent in aldehyde **B** as well as the electronic effect of the EDG substituent in aldehyde **A** are both *Z*-directing. Consequently, both reactions give rise to predominantly the *Z*-isomer.

The above data show that the *ortho*-effect²⁹ is an important aspect to consider when coupling two benzaldehydes. *ortho*-Substituents on aldehyde **B** exhibit a *Z*-directing effect, while those on aldehyde **A** are largely of electronic nature, and thus follow the trends from Table 1. As a result, it is possible to also direct the synthesis of a specific stilbene with *ortho*-substituents towards one or the other isomer by choosing the right order of addition of the two aldehydes. For example, when comparing entries 1 and 4, *ortho*-bromo-stilbene can intentionally be produced either with 100% *E*-selectivity, or in the *Z*-enriched form as a 1 : 2 isomeric mixture.

Summarizing the findings above, it is the electronic nature of aldehyde **A** and the *ortho*-effect of aldehyde **B** that determine the isomeric preference of the reaction. Depending on

Table 2 *E*- and *Z*-Stilbenes by the coupling of two *ortho*-substituted benzaldehydes. *X* = H, Br, Me, and OMe on aldehyde **A**. *Y* = H, Br, Me, and OMe on aldehyde **B**. Reaction conditions as in Scheme 2. *E–Z* ratios are determined from isolated stilbenes

Entry	Aldehyde A	Aldehyde B	Isolated yield, %	<i>E–Z</i> ratio

9	OMe	OMe	57	36/64

Scheme 3 Example of how the electronic nature of aldehyde **A** and the *ortho*-effect on aldehyde **B** can be used to direct product isomer distribution.

the exact structure of the starting aldehydes, the two effects can oppose or support each other, and can be used to control and predict the product stereochemistry. In certain combinations, changing the order of addition can have striking effects. One such example is illustrated in the coupling of *p*-methoxybenzaldehyde with *o*-bromobenzaldehyde (Scheme 3). If the former is used as aldehyde **A** and the latter as aldehyde **B**, the *Z*-alkene is formed predominantly due to the *ortho*-effect of aldehyde **B** and the EDG on aldehyde **A**, both of which are *Z*-directing (Scheme 3a).

By reversing the order of addition, the *ortho*-bromide substituent now only exerts its electronic EWG effect and is *E*-directing, while the methoxy group in the *para*-position in aldehyde **B** has no effect. Consequently, the reaction is 100% *E*-selective (Scheme 3b). The examples in Scheme 3c and d follow the same rationale. In the coupling of electron-rich aldehyde **A** with a morpholino group in the *para*-position and *o*-bromobenzaldehyde as aldehyde **B**, both substituents are *Z*-directing. Conversely, with a reversed order of addition of the two coupling partners, the opposite isomer is predominantly formed (Scheme 3d).

Conclusions

E- and *Z*-Enriched stilbenes can be synthesized by the coupling of two differently substituted benzaldehydes. Owing to the sequential addition of the two coupling partners at different stages of the sequence, different *E*- and *Z*-directing effects on the two aldehydes can be exploited. Chart 1 represents a practical tool to predict which combination of substituents can be used to direct the synthesis towards *E*- or *Z*-enriched stilbenes. In the left column, substrate combinations that give rise to *Z*-enriched stilbenes are depicted. These contain examples where aldehyde **A** has an EDG, or where aldehyde **B** features an *ortho*-substituent. Conversely, as summarized in the right column, *E*-stilbenes are formed from electron-deficient aldehydes **A**, irrespective of the structure of aldehyde **B**. None of these opportunities are available with related carbonyl–carbonyl cross-couplings such as the McMurry reaction, or also

more recent reports on the topic including transition-metal catalyzed variants.³⁶ One limitation of the procedure, though, is the incompatibility of the procedure for the coupling of aldehydes with acidic protons due to acid–base chemistry with phosphorus based reagents **1** and **3**. The isolated yields presented herein range from 32 to 75%, depending on the exact nature of the substituents and the reactivity they impose. While being admittedly modest, it is important to remember that these yields are isolated yields of one-pot coupling reactions. As such, they compare favorably with the overall yields of 2–3 step synthetic procedures that are typical in the Wittig-type olefinations.^{9,37} We therefore believe that the results presented herein can be useful in the preparation of pharmaceutically relevant compounds, which is the subject of on-going efforts in our group.

Experimental section

Materials and methods

The first half of the reaction up to the addition of MeOH was carried out in a glove box, while the second part can be conducted using regular Schlenk techniques. Glassware was flame-dried, and aldehydes dried/distilled prior to use. THF and Et₂O were freshly distilled over Na/benzophenone under nitrogen. MesP(TMS)₂ was synthesized according to literature procedures.³⁸ ^tBuOOH was dried with an azeotrope distillation of water and benzene from a commercial water solution of the peroxide. LiOEt and ^tBuOK were both used as a commercially available 1 M solution in THF. All the carbonyl compounds are commercially available. NMR spectra were recorded on a JEOL (400YH magnet) Resonance 400 MHz spectrometer. Chemical shifts (δ) are reported in ppm and coupling constants *J* in Hz. ¹H NMR and ¹³C NMR chemical shifts are referenced to the residual protic solvent signal and ³¹P NMR spectra externally to 85% H₃PO₄(aq.). High-resolution mass spectra (HR-MS) were recorded on a Bruker QTOF spectrometer.

Preparation of MesP(Li)TMS

To a solution of MesP(TMS)₂ (1 eq., 1.60 g, 5.4 mmol) in 40 mL of dry THF was added a 1 M THF solution of LiOEt (1 eq.) at room temperature. The reaction mixture was stirred at ambient temperature for 4 hours until full conversion of the starting material to MesP(Li)TMS **1** was achieved, as judged from its typical P NMR shift (−187 ppm). The solvent was removed under reduced pressure to afford MesP(Li)TMS **1** as an orange oil without further purification. Dry Et₂O was added and the yellow solution was stored in a glove box until further use for up to one month without visible changes.

Detailed general procedure for the coupling of two aldehydes to stilbenes (Scheme 2)

To a yellow solution of **1** (1 eq., 351 mg, 1.52 mmol) in 15 mL dry Et₂O were added 0.9 eq. of a first aldehyde (RCHO, R = Ph, Table 1, entry 8; 0.9 eq., 145 mg, 1.37 mmol) at ambient temperature; upon this addition, the reaction mixture changes

Chart 1 X = EDG, EWG, H; substitution on the first aldehyde. Y = EDG, EWG, H; substitution on the second coupling partner.

immediately from bright yellow to a pale limpid yellow solution. The formation of the phosphalkene **2** was monitored by ^{31}P NMR using an external C_6D_6 standard. After complete formation, achieved within a few minutes, 0.2 mL of MeOH was added at room temperature with stirring. Upon addition of MeOH, the reaction mixture becomes immediately turbid. After 5 minutes, 1.2 eq. of $t\text{BuOOH}$ were added to the reaction mixture at room temperature; no changes are visible after addition of the oxidant. The reaction was monitored by ^{31}P NMR. Complete conversion to the desired phosphinate intermediate **3** is usually achieved within 5 minutes. The solvent was removed under vacuum and freshly distilled THF (15 mL) was added under an argon flow; the color of the reaction mixture at this stage is pale yellow. 0.9 eq. of a second aldehyde (RCHO , $\text{R} = \text{Ph}$, Table 1, entry 8; 0.9 eq., 145 mg, 1.37 mmol) were added to the reaction mixture, followed by 1.5 eq. of a 1 M THF solution of $t\text{BuOK}$; upon addition of the base, the mixture changes to a deep and limpid orange color. The reaction mixture was stirred at room temperature until phosphinate **3** is fully consumed. After completion of the reaction, water was added to the mixture. The aqueous phase was extracted with Et_2O . The organic phase was dried over MgSO_4 , and the solvent was removed under reduced pressure to afford the crude product. The olefinic product was purified *via* silica gel column chromatography with a mixture of 5% of EtOAc in heptane. Isolated yield: 130 mg, 52%.

Upscaling the reaction to gram scale (Scheme 2)

To a yellow solution of **1** (1 eq., 932 mg, 4.05 mmol) in 25 mL dry Et_2O were added 0.9 eq. of a first aldehyde (RCHO , $\text{R} = p\text{-CH}_3\text{-Ph}$, Table 1, entry 12; 0.9 eq., 437 mg, 3.64 mmol) at ambient temperature; upon this addition, the reaction mixture changes immediately from bright yellow to a pale limpid yellow solution. After stirring at ambient temperature for 5 minutes, 1 mL of MeOH was added, upon which the reaction mixture turns turbid immediately. After 5 minutes, 1.2 eq. of $t\text{BuOOH}$ were added at room temperature, resulting in an exothermic reaction. The reaction was monitored by ^{31}P NMR. Complete conversion to the desired phosphinate intermediate **3** is achieved within 5 minutes. The solvent was removed under vacuum and freshly distilled THF (25 mL) was added under an argon flow; the color of the reaction mixture at this stage is pale yellow. 0.9 eq. of a second aldehyde (RCHO , $\text{R} = p\text{-Br-Ph}$, Table 1, entry 12; 0.9 eq., 637 mg, 3.63 mmol) were added to the reaction mixture, followed by 1.5 eq. of a 1 M THF solution of $t\text{BuOK}$; upon addition of the base, the mixture changes to a deep and limpid orange color. Also in this case, the reaction is slightly exothermic. The reaction mixture was stirred at room temperature until full consumption of phosphinate **3**. After completion of the reaction, water was added to the mixture. The aqueous phase was extracted with Et_2O . The organic phase was dried over MgSO_4 , and the solvent was removed under reduced pressure to afford the crude product. The olefinic product was purified *via* silica gel column chromatography with a mixture of 5% of EtOAc in heptane. Isolated yield: 558 mg, 56%. *E/Z* ratio: 60/40.

NMR spectroscopic data and the list of olefins

(*E-Z*) 1-Bromo-4-styrylbenzene (Table 1, entry 1). The product was purified *via* silica gel column chromatography with 5% EtOAc in heptane and it was isolated as a mixture of *E*- and *Z*-olefins with a total yield of 46%, 72 mg, colorless solid. Analytical data of the compounds are in agreement with the reported literature values.^{39,40} The *E/Z* ratio was determined based on the characteristic olefinic signals of the two isomers. ^1H NMR (CDCl_3 , 400 MHz, 300 K): $\delta = 7.02$ (d, $^3J = 16.3$ Hz, CH for the *E*-product), 6.63 (d, $^3J = 12.2$ Hz, CH for the *Z* product), 6.50 (d, $^3J = 12.2$ Hz, CH for the *Z*-product). Signals of the *E*-isomer: 7.53–7.44 (m, 4H), 7.40–7.32 (m, 4H), 7.32–7.23 (m, 1H), 7.09 (d, $^3J = 16.3$ Hz, 1H), 7.02 (d, $^3J = 16.3$ Hz, 1H). Signals of the *Z*-isomer: 7.38–7.33 (m, 2H), 7.29–7.20 (m, 7H), 6.63 (d, $^3J = 12.2$ Hz, 1H), 6.50 (d, $^3J = 12.2$ Hz, 1H).

(*E-Z*) 1-Methyl-4-styrylbenzene (Table 1, entry 2). The product was purified *via* silica gel column chromatography with 5% EtOAc in heptane and it was isolated as a mixture of *E*- and *Z*-olefins with a total yield of 52%, 61 mg, white solid. Analytical data of the compounds are in agreement with the reported literature values.⁴¹ The *E/Z* ratio was determined based on the characteristic signals of the $p\text{CH}_3$ of the two isomers. ^1H NMR (CDCl_3 , 400 MHz, 300 K): $\delta = 2.36$ (s, CH_3 for the *E*-product), 2.30 (s, CH_3 for the *Z*-product). Signals of the *E*-isomer: 7.51–7.49 (m, 2H), 7.42–7.40 (m, 2H), 7.38–7.33 (m, 2H), 7.27–7.22 (m, 2H), 7.13–7.07 (m, 3H), 2.36 (s, 3H). Signals of the *Z*-isomer: 7.17–7.11 (m, 7H), 7.02 (d, $J = 7.9$ Hz, 2H), 6.55 (s, 2H), 2.30 (s, 3H).

(*E-Z*) 1-Methoxy-4-styrylbenzene (Table 1, entry 3). The product was purified *via* silica gel column chromatography with 6% EtOAc in heptane and it was isolated as a mixture of *E*- and *Z*-olefins with a total yield of 75%, 96 mg, pale yellow solid. Analytical data of the compounds are in agreement with the reported literature values.⁴¹ The *E/Z* ratio was determined based on the characteristic olefinic signals of the two isomers. ^1H NMR (CDCl_3 , 400 MHz, 300 K): $\delta = 7.06$ (d, $^3J = 16.3$ Hz, CH for the *E*-product), 6.97 (d, $^3J = 16.3$ Hz, CH for the *E*-product), 6.53 (d, $^3J = 12.2$ Hz, CH for the *Z*-product), 6.49 (d, $J = 12.2$ Hz, CH for the *Z*-product). Signals of the *E*-isomer: 7.49–7.44 (m, 4H), 7.35–7.32 (m, 2H), 7.27–7.23 (m, 1H), 7.06 (d, $^3J = 16.3$ Hz, 1H), 6.97 (d, $^3J = 16.3$ Hz, 1H), 6.95–6.87 (m, 2H), 3.82 (s, 3H). Signals of the *Z*-isomer: 7.27–7.16 (m, 7H), 6.76–6.73 (m, 2H), 6.53 (d, $^3J = 12.2$ Hz, 1H), 6.49 (d, $^3J = 12.2$ Hz, 1H), 3.78 (s, 3H).

(*E*)-1-Bromo-4-styrylbenzene (Table 1, entry 4). The product was purified *via* silica gel column chromatography with 5% EtOAc in heptane and it was isolated as pure *E*-olefin, yield 45%, 87 mg, colorless solid. Analytical data of the compound are in agreement with the reported literature values.³⁹ ^1H NMR (CDCl_3 , 400 MHz, 300 K) $\delta = 7.53$ –7.44 (m, 4H), 7.40–7.32 (m, 4H), 7.32–7.23 (m, 1H), 7.09 (d, $^3J = 16.3$ Hz, 1H), 7.02 (d, $^3J = 16.3$ Hz, 1H).

(*E-Z*) 1-Methyl-4-styrylbenzene (Table 1, entry 5). The product was purified *via* silica gel column chromatography with 5% EtOAc in heptane and it was isolated as a mixture of

E- and *Z*-olefins with a total yield of 39%, 47 mg, white solid. Analytical data of the compounds are in agreement with the reported literature values.⁴¹ The *E/Z* ratio was determined based on the characteristic signals of the *p*CH₃ of the two isomers. ¹H NMR (CDCl₃, 400 MHz, 300 K): δ = 2.36 (s, CH₃ for the *E*-product), 2.30 (s, CH₃ for the *Z*-product). Signals of the *E*-isomer: 7.51–7.49 (m, 2H), 7.42–7.40 (m, 2H), 7.38–7.33 (m, 2H), 7.27–7.22 (m, 2H), 7.13–7.07 (m, 3H), 2.36 (s, 3H). Signals of the *Z*-isomer: 7.17–7.11 (m, 7H), 7.02 (d, *J* = 7.9 Hz, 2H), 6.55 (s, 2H), 2.30 (s, 3H).

(*E-Z*) 1-Methoxy-4-styrylbenzene (Table 1, entry 6). The product was purified *via* silica gel column chromatography with a mixture of 6% of EtOAc in heptane and it was isolated as a mixture of *E*- and *Z*-olefins with a total yield of 57%, 73 mg, pale yellow solid. Analytical data of the compounds are in agreement with the reported literature values.⁴¹ The *E/Z* ratio was determined based on the characteristic olefinic signals of the two isomers. ¹H NMR (CDCl₃, 400 MHz, 300 K): δ = 7.06 (d, ³*J* = 16.3 Hz, CH for the *E*-product), 6.97 (d, ³*J* = 16.3 Hz, CH for the *E*-product), 6.53 (d, ³*J* = 12.2 Hz, CH for the *Z*-product), 6.49 (d, ³*J* = 12.2 Hz, CH for the *Z*-product). Signals of the *E*-isomer: 7.49–7.44 (m, 4H), 7.35–7.32 (m, 2H), 7.27–7.23 (m, 1H), 7.06 (d, ³*J* = 16.3 Hz, 1H), 6.97 (d, ³*J* = 16.3 Hz, 1H), 6.95–6.87 (m, 2H), 3.82 (s, 3H). Signals of the *Z*-isomer: 7.27–7.16 (m, 7H), 6.76–6.73 (m, 2H), 6.53 (d, ³*J* = 12.2 Hz, 1H), 6.49 (d, ³*J* = 12.2 Hz, 1H), 3.78 (s, 3H).

(*E*)-1,2-Bis(4-bromophenyl)ethene (Table 1, entry 7). The product was purified *via* silica gel column chromatography with 5% EtOAc in heptane and it was isolated as pure *E*-olefin, yield 58%, 56 mg, colorless solid. Analytical data of the compound are in agreement with the reported literature values.⁴² ¹H NMR (CDCl₃, 400 MHz, 300 K) δ = 7.49–7.45 (m, 4H), 7.38–7.33 (m, 4H), 7.01 (s, 2H).

(*E-Z*)-1,2-Diphenylethene (Table 1, entry 8). The product was purified *via* silica gel column chromatography with 5% EtOAc in heptane and it was isolated as a mixture of *E*- and *Z*-olefins with a total yield of 52%, 130 mg, colorless solid. Analytical data of the compound are in agreement with the reported literature values.⁴¹ The *E/Z* ratio was determined based on the characteristic olefinic signals of the two isomers. ¹H NMR (CDCl₃, 400 MHz, 300 K) δ = 7.11 (s, CH for the *E*-product), 6.60 (s, CH for the *Z*-product). Signals of the *E*-isomer: ¹H NMR (CDCl₃, 400 MHz, 300 K) δ = 7.53–7.50 (m, 4H), 7.38–7.34 (m, 4H), 7.28–7.18 (m, 2H), 7.11 (s, 2H). Signals of the *Z*-isomer: ¹H NMR (CDCl₃, 400 MHz, 300 K) δ = 7.28–7.18 (m, 10H), 6.60 (s, 2H).

(*E-Z*) 1,2-Di-*p*-tolylethene (Table 1, entry 9). The product was purified *via* silica gel column chromatography with 5% EtOAc in heptane and it was isolated as a mixture of *E*- and *Z*-olefins with a total yield of 44%, 55 mg, white solid. Analytical data of the compounds are in agreement with the reported literature values.^{43,44} The *E/Z* ratio was determined based on the characteristic signals of the *p*CH₃ of the two isomers. ¹H NMR (CDCl₃, 400 MHz, 300 K): δ = 2.35 (s, CH₃ for the *E*-product), 2.30 (s, CH₃ for the *Z*-product). Signals of the *E*-isomer: 7.40–7.38 (m, 4H), 7.18–7.14 (m, 4H), 7.03 (s, 2H), 2.35 (s, 6H).

Signals of the *Z*-isomer: 7.16–7.14 (m, 4H), 7.03–7.01 (m, 4H), 6.50 (s, 2H), 2.30 (s, 6H).

(*E*)-1,2-Bis(4-methoxyphenyl)ethene (Table 1, entry 10). The product was purified *via* silica gel column chromatography with 6% EtOAc in heptane and it was isolated as pure *E*-olefin, yield 20%, 40 mg, colorless solid. Analytical data of the compound are in agreement with the reported literature values.⁴⁵ ¹H NMR (CDCl₃, 400 MHz, 300 K) δ = 7.44–7.39 (m, 4H), 6.92 (s, 2H), 6.90–6.85 (m, 4H), 3.82 (s, 6H).

(*Z*)-1,2-Bis(4-methoxyphenyl)ethene (Table 1, entry 10). The product was purified *via* silica gel column chromatography with 6% EtOAc in heptane and it was isolated as pure *Z*-olefin, yield 20%, 40 mg, colorless solid. Analytical data of the compound are in agreement with the reported literature values.⁴⁶ ¹H NMR (CDCl₃, 400 MHz, 300 K) δ = 7.23–7.16 (m, 4H), 6.80–6.74 (m, 4H), 6.45 (s, 2H), 3.79 (s, 6H).

(*E*)-1-Bromo-4-(4-methylstyryl)benzene (Table 1, entry 11). The product was purified *via* silica gel column chromatography with 5% EtOAc in heptane and it was isolated as pure *E*-olefin, yield 32%, 31 mg, white solid. Analytical data of the compound are in agreement with the reported literature values.⁴⁷ ¹H NMR (CDCl₃, 400 MHz, 300 K) δ = 7.46–7.44 (m, 2H), 7.40–7.38 (m, 2H), 7.36–7.34 (m, 2H), 7.17–7.15 (m, 2H), 7.06 (d, ³*J* = 16.3 Hz, 1H), 6.97 (d, ³*J* = 16.3 Hz, 1H), 2.35 (s, 3H).

(*E*)-1-Bromo-4-(4-methylstyryl)benzene (Table 1, entry 12). The product was purified *via* silica gel column chromatography with 5% EtOAc in heptane and it was isolated as pure *E*-olefin, yield 36%, 38 mg, white solid. Analytical data of the compound are in agreement with the reported literature values.⁴⁷ ¹H NMR (CDCl₃, 400 MHz, 300 K) δ = 7.46–7.44 (m, 2H), 7.40–7.38 (m, 2H), 7.36–7.34 (m, 2H), 7.17–7.15 (m, 2H), 7.06 (d, ³*J* = 16.3 Hz, 1H), 6.97 (d, ³*J* = 16.3 Hz, 1H), 2.35 (s, 3H).

(*Z*)-1-Bromo-4-(4-methylstyryl)benzene (Table 1, entry 12). The product was purified *via* silica gel column chromatography with 5% EtOAc in heptane and it was isolated as pure *Z*-olefin, yield 38%, 40 mg, colorless oil. Analytical data of the compound are in agreement with the reported literature values.⁴⁷ ¹H NMR (CDCl₃, 400 MHz, 300 K) δ = 7.34–7.31 (m, 2H), 7.12–7.09 (m, 4H), 7.04–7.02 (m, 2H), 6.57 (d, ³*J* = 12.1 Hz, 1H), 6.45 (d, ³*J* = 12.1 Hz, 1H), 2.31 (s, 3H).

(*E*)-1-Bromo-4-(4-methoxystyryl)benzene (Table 1, entry 13). The product was purified *via* silica gel column chromatography with 6% EtOAc in heptane and it was isolated as pure *E*-olefin, yield 35%, 62 mg, white solid. Analytical data of the compound are in agreement with the reported literature values.⁴⁵ ¹H NMR (CDCl₃, 400 MHz, 300 K) δ = 7.47–7.41 (m, 4H), 7.36–7.31 (m, 2H), 7.04 (d, ³*J* = 16.3 Hz, 1H), 6.93–6.85 (m, 3H), 3.82 (s, 3H).

(*E*)-1-Bromo-4-(4-methoxystyryl)benzene (Table 1, entry 14). The product was purified *via* silica gel column chromatography with 6% EtOAc in heptane and it was isolated as pure *E*-olefin, yield 14%, 26 mg, white solid. Analytical data of the compound are in agreement with the reported literature values.⁴⁵ ¹H NMR (CDCl₃, 400 MHz, 300 K) δ = 7.47–7.41 (m,

4H), 7.36–7.31 (m, 2H), 7.04 (d, $^3J = 16.3$ Hz, 1H), 6.93–6.85 (m, 3H), 3.82 (s, 3H).

(Z)-1-Bromo-4-(4-methoxystyryl)benzene (Table 1, entry 14). The product was purified *via* silica gel column chromatography with 6% EtOAc in heptane and it was isolated as pure Z-olefin, yield 34%, 60 mg, white solid. Analytical data of the compound are in agreement with the reported literature values.⁴⁸ ^1H NMR (CDCl_3 , 400 MHz, 300 K) $\delta = 7.36\text{--}7.32$ (m, 2H), 7.17–7.10 (m, 4H), 6.78–6.73 (m, 2H), 6.55 (d, $^3J = 12.2$ Hz, 1H), 6.40 (d, $^3J = 12.2$ Hz, 1H), 3.78 (s, 3H).

(E-Z) 1-Bromo-2-styrylbenzene (Table 2, entry 1). The product was purified *via* silica gel column chromatography with 5% EtOAc in heptane and it was isolated as a mixture of E- and Z-olefins with a total yield of 51%, 60 mg, pale yellow oil. Analytical data of the compounds are in agreement with the reported literature values.⁴⁹ The E/Z ratio was determined based on the characteristic olefinic signals of the two isomers. ^1H NMR (CDCl_3 , 400 MHz, 300 K): $\delta = 7.48$ (d, $^3J = 16.2$ Hz, CH for the E-product), 7.05 (d, $^3J = 16.2$ Hz, CH for the E-product), 6.70 (d, $^3J = 12.1$ Hz, CH for the Z-product), 6.63 (d, $^3J = 12.1$ Hz, CH for the Z-product). Signals of the E-isomer: $\delta = 7.67$ (dd, $J = 7.8, 1.6$ Hz, 1H), 7.62–7.53 (m, 3H), 7.48 (d, $^3J = 16.2$ Hz, 1H), 7.42–7.36 (m, 2H), 7.34–7.27 (m, 2H), 7.16–7.09 (m, 1H), 7.05 (d, $^3J = 16.2$ Hz, 1H). Signals of the Z-isomer: 7.61–7.55 (m, 1H), 7.20–7.13 (m, 6H), 7.10–7.07 (m, 2H), 6.70 (d, $^3J = 12.1$ Hz, 1H), 6.63 (d, $^3J = 12.1$ Hz, 1H).

(E-Z) 1-Methyl-2-styrylbenzene (Table 2, entry 2). The product was purified *via* silica gel column chromatography with 5% EtOAc in heptane and it was isolated as a mixture of E- and Z-olefins with a total yield of 38%, 45 mg, colorless oil. Analytical data of the compounds are in agreement with the reported literature values.⁴¹ The E/Z ratio was determined based on the characteristic olefinic signals of the two isomers. ^1H NMR (CDCl_3 , 400 MHz, 300 K): $\delta = 7.01$ (d, $^3J = 16.3$ Hz, CH for the E-product), 6.62 (d, $^3J = 12.3$ Hz, CH for the Z-product). Signals of the E-isomer: 7.66–7.64 (m, 1H), 7.58–7.56 (m, 2H), 7.43–7.37 (m, 3H), 7.33–7.19 (m, 4H), 7.01 (d, $^3J = 16.3$ Hz, 1H), 2.48 (s, 3H). Signals of the Z-isomer: 7.33–7.19 (m, 9H), 6.64 (d, $^3J = 12.3$ Hz, 1H), 6.62 (d, $^3J = 12.3$ Hz, 1H), 2.32 (s, 3H).

(E-Z) 1-Methoxy-2-styrylbenzene (Table 2, entry 3). The product was purified *via* silica gel column chromatography with 6% EtOAc in heptane and it was isolated as a mixture of E- and Z-olefins with a total yield of 67%, 65 mg, yellow oil. Analytical data of the compounds are in agreement with the reported literature values.⁵⁰ The E/Z ratio was determined based on the characteristic olefinic signals of the two isomers. ^1H NMR (CDCl_3 , 400 MHz, 300 K): $\delta = 7.52$ (d, $^3J = 16.5$ Hz, CH for the E-product), 7.13 (d, $^3J = 16.5$ Hz, CH for the E-product), 6.72 (d, $^3J = 12.3$ Hz, CH for the Z-product), 6.65 (d, $^3J = 12.3$ Hz, CH for the Z-product). Signals of the E-isomer: 7.63–7.61 (m, 1H), 7.57–7.55 (m, 2H), 7.52 (d, $^3J = 16.5$ Hz, 1H), 7.39–7.35 (m, 2H), 7.28–7.25 (m, 2H), 7.13 (d, $^3J = 16.5$ Hz, 1H), 7.01–6.97 (m, 1H), 6.93–6.89 (m, 1H), 3.90 (s, 3H). Signals of the Z-isomer: 7.23–7.18 (m, 7H), 6.91–6.89 (m, 1H), 6.79–6.76 (m, 1H), 6.72 (d, $^3J = 12.3$ Hz, 1H), 6.65 (d, $^3J = 12.3$ Hz, 1H), 3.83 (s, 3H).

(E) 1-Bromo-2-styrylbenzene (Table 2, entry 4). The product was purified *via* silica gel column chromatography with 5% EtOAc in heptane and it was isolated as pure E-olefin, yield 43%, 50 mg, 43%, pale yellow oil. Analytical data of the compounds are in agreement with the reported literature values.⁴⁹ ^1H NMR (CDCl_3 , 400 MHz, 300 K): $\delta = 7.67$ (dd, $J = 7.8, 1.6$ Hz, 1H), 7.62–7.53 (m, 3H), 7.48 (d, $^3J = 16.2$ Hz, 1H), 7.42–7.36 (m, 2H), 7.34–7.27 (m, 2H), 7.16–7.09 (m, 1H), 7.05 (d, $^3J = 16.2$ Hz, 1H).

(E-Z) 1-Methyl-2-styrylbenzene (Table 2, entry 5). The product was purified *via* silica gel column chromatography with 5% EtOAc in heptane and it was isolated as a mixture of E- and Z-olefins with a total yield of 76%, 81 mg, colorless oil. Analytical data of the compounds are in agreement with the reported literature values.⁴¹ The E/Z ratio was determined based on the characteristic olefinic signals of the two isomers. ^1H NMR (CDCl_3 , 400 MHz, 300 K): $\delta = 7.01$ (d, $^3J = 16.3$ Hz, CH for the E-product), 6.62 (d, $^3J = 12.3$ Hz, CH for the Z-product). Signals of the E-isomer: 7.66–7.64 (m, 1H), 7.58–7.56 (m, 2H), 7.43–7.37 (m, 3H), 7.33–7.19 (m, 4H), 7.01 (d, $^3J = 16.3$ Hz, 1H), 2.48 (s, 3H). Signals of the Z-isomer: 7.33–7.19 (m, 9H), 6.64 (d, $^3J = 12.3$ Hz, 1H), 6.62 (d, $^3J = 12.3$ Hz, 1H), 2.32 (s, 3H).

(E-Z) 1-Methoxy-2-styrylbenzene (Table 2, entry 6). The product was purified *via* silica gel column chromatography with 6% EtOAc in heptane and it was isolated as a mixture of E- and Z-olefins with a total yield of 57%, 55 mg, yellow oil. Analytical data of the compounds are in agreement with the reported literature values.⁵⁰ The E/Z ratio was determined based on the characteristic olefinic signals of the two isomers. ^1H NMR (CDCl_3 , 400 MHz, 300 K): $\delta = 7.52$ (d, $^3J = 16.5$ Hz, CH for the E-product), 7.13 (d, $^3J = 16.5$ Hz, CH for the E-product), 6.72 (d, $^3J = 12.3$ Hz, CH for the Z-product), 6.65 (d, $^3J = 12.3$ Hz, CH for the Z-product). Signals of the E-isomer: 7.63–7.61 (m, 1H), 7.57–7.55 (m, 2H), 7.52 (d, $^3J = 16.5$ Hz, 1H), 7.39–7.35 (m, 2H), 7.28–7.25 (m, 2H), 7.13 (d, $^3J = 16.5$ Hz, 1H), 7.01–6.97 (m, 1H), 6.93–6.89 (m, 1H), 3.90 (s, 3H). Signals of the Z-isomer: 7.23–7.18 (m, 7H), 6.91–6.89 (m, 1H), 6.79–6.76 (m, 1H), 6.72 (d, $^3J = 12.3$ Hz, 1H), 6.65 (d, $^3J = 12.3$ Hz, 1H), 3.83 (s, 3H).

(E-Z) 1,2-Bis(2-bromophenyl)ethene (Table 2, entry 7). The product was purified *via* silica gel column chromatography with 5% EtOAc in heptane and it was isolated as a mixture of E- and Z-olefins with a total yield of 36%, 55 mg, white solid. Analytical data of the compounds are in agreement with the reported literature values.^{37,51} The E/Z ratio was determined based on the characteristic olefinic signals of the two isomers. ^1H NMR (CDCl_3 , 400 MHz, 300 K): $\delta = 7.40$ (s, CH for the E-product), 6.78 (s, CH for the Z-product). Signals of the E-isomer: 7.72 (dd, $J = 7.6, 1.6$ Hz, 2H), 7.59 (dd, $J = 8.1, 1.2$ Hz, 2H), 7.40 (s, 2H), 7.33 (td, $J = 7.6, 1.2$ Hz, 2H), 7.17–7.12 (m, 2H). Signals of the Z-isomer: 7.57–7.55 (m, 2H), 7.07–6.95 (m, 6H), 6.78 (s, 2H).

(E-Z) 1,2-Di-*o*-tolylethene (Table 2, entry 8). The product was purified *via* silica gel column chromatography with 5% EtOAc in heptane and it was isolated as a mixture of E- and Z-olefins with a total yield of 33%, 37 mg, white solid. Analytical data of

the compounds are in agreement with the reported literature values.^{52,53} The *E/Z* ratio was determined based on the characteristic signals of the *o*CH₃ of the two isomers. ¹H NMR (CDCl₃, 400 MHz, 300 K): δ = 2.44 (s, CH₃ for the *E*-product), 2.30 (s, CH₃ for the *Z*-product). Signals of the *E*-isomer: 7.62–7.60 (m, 2H), 7.28–7.20 (m, 8H), 2.44 (s, 6H). Signals of the *Z*-isomer: 7.16–7.14 (m, 2H), 7.11–7.07 (m, 2H), 6.96–6.91 (m, 4H), 6.73 (s, 2H), 2.30 (s, 6H).

(*E-Z*) 1,2-Bis(2-methoxyphenyl)ethene (Table 2, entry 9). The product was purified *via* silica gel column chromatography with 6% EtOAc in heptane and it was isolated as a mixture of *E*- and *Z*-olefins with a total yield of 57%, 63 mg, yellow solid. Analytical data of the compounds are in agreement with the reported literature values.⁵⁴ The *E/Z* ratio was determined based on the characteristic olefinic signals of the two isomers. ¹H NMR (CDCl₃, 400 MHz, 300 K): δ = 7.49 (s, CH for the *E*-product), 6.78 (s, CH for the *Z*-product). Signals of the *E*-isomer: 7.67 (dd, *J* = 7.6, 1.5 Hz, 2H), 7.49 (s, 2H), 7.25–7.21 (m, 2H), 6.99–6.96 (m, 2H), 6.91–6.86 (m, 2H), 3.88 (s, 6H). Signals of the *Z*-isomer: 7.20–7.15 (m, 2H), 7.14 (dd, *J* = 7.6, 1.7 Hz, 2H), 6.92–6.84 (m, 2H), 6.78 (s, 2H), 6.71 (td, *J* = 7.5, 1.0 Hz, 2H), 3.83 (s, 6H).

(*E-Z*) 1-Bromo-2-(4-methoxystyryl)benzene (Scheme 3a). The product was purified *via* silica gel column chromatography with 6% EtOAc in heptane and it was isolated as a mixture of *E*- and *Z*-olefins with a total yield of 54%, 96 mg, pale yellow solid. Analytical data of the compounds are in agreement with the reported literature values.⁵⁵ The *E/Z* ratio was determined based on the characteristic olefinic signals of the two isomers. ¹H NMR (CDCl₃, 400 MHz, 300 K): δ = 7.32 (d, ³*J* = 16.2 Hz, CH for the *E*-product), 6.99 (d, ³*J* = 16.2 Hz, CH for the *E*-product), 6.62 (d, ³*J* = 12.1 Hz, CH for the *Z*-product), 6.50 (d, ³*J* = 12.1 Hz, CH for the *Z*-product). Signals of the *E*-isomer: 7.64 (dd, ⁴*J* = 7.9, 1.6 Hz, 1H), 7.56 (dd, ⁴*J* = 7.9, 1.6 Hz, 1H), 7.51–7.46 (m, 2H), 7.32 (d, ³*J* = 16.2 Hz, 1H), 7.29–7.26 (m, 1H), 7.12–7.05 (m, 1H), 6.99 (d, ³*J* = 16.2 Hz, 1H), 6.93–6.87 (m, 2H), 3.83 (s, 3H). Signals of the *Z*-isomer: 7.61–7.59 (m, 1H), 7.24–7.22 (m, 1H), 7.13–7.06 (m, 4H), 6.73–6.99 (m, 2H), 6.62 (d, ³*J* = 12.1 Hz, 1H), 6.50 (d, ³*J* = 12.1 Hz, 1H), 3.76 (s, 3H).

(*E*-1-Bromo-2-(4-methoxystyryl)benzene (Scheme 3b). The product was purified *via* silica gel column chromatography with 6% of EtOAc in heptane and it was isolated as pure *E*-olefin, yield 34%, 52 mg, pale yellow solid. Analytical data of the compound are in agreement with the reported literature values.⁵⁵ ¹H NMR (CDCl₃, 400 MHz, 300 K): δ = 7.64 (dd, ⁴*J* = 7.9, 1.6 Hz, 1H), 7.56 (dd, ⁴*J* = 7.9, 1.6 Hz, 1H), 7.51–7.46 (m, 2H), 7.32 (d, ³*J* = 16.2 Hz, 1H), 7.29–7.26 (m, 1H), 7.12–7.05 (m, 1H), 6.99 (d, ³*J* = 16.2 Hz, 1H), 6.93–6.87 (m, 2H), 3.83 (s, 3H).

(*E-Z*)-4-(4-(2-Bromostyryl)phenyl)morpholine (Scheme 3c). The product was purified *via* silica gel column chromatography with 6% EtOAc in heptane and it was isolated as a mixture of *E*- and *Z*-olefins with a total yield of 48%, 93 mg, colorless oil. The *E/Z* ratio was determined based on the characteristic olefinic signals of the two isomers. ¹H NMR (CDCl₃, 400 MHz, 300 K): δ = 6.97 (d, ³*J* = 16.1 Hz, CH for the *E*-product), 6.47 (d, ³*J* = 12.1 Hz, CH for the *Z*-product). Signals

of the *E*-isomer: 7.65–7.63 (m, 1H), 7.57–7.55 (m, 1H), 7.48–7.46 (m, 2H), 7.33–7.26 (m, 2H), 7.09–7.05 (m, 1H), 6.97 (d, ³*J* = 16.1 Hz, 1H), 6.92–6.90 (broad m, 2H), 3.88–3.86 (m, 4H), 3.22–3.19 (m, 4H). Signals of the *Z*-isomer: 7.59 (dd, *J* = 7.6, 1.6 Hz, 1H), 7.13–7.03 (m, 5H), 6.78–6.66 (broad m, 2H), 6.58 (d, ³*J* = 12.1 Hz, 1H), 6.47 (d, ³*J* = 12.1 Hz, 1H), 3.85–3.70 (m, 4H), 3.17–3.07 (m, 4H).

(*E*)-4-(4-(2-Bromostyryl)phenyl)morpholine (Scheme 3d). The product was purified *via* silica gel column chromatography with 6% EtOAc in heptane and it was isolated as pure *E*-olefin, yield 45%, 54 mg, white solid. ¹H NMR (CDCl₃, 400 MHz, 300 K): δ = 7.65–7.63 (m, 1H), 7.57–7.55 (m, 1H), 7.48–7.46 (m, 2H), 7.33–7.26 (m, 2H), 7.09–7.05 (m, 1H), 6.97 (d, ³*J* = 16.1 Hz, 1H), 6.92–6.90 (broad m, 2H), 3.88–3.86 (m, 4H), 3.22–3.19 (m, 4H). ¹³C NMR (CDCl₃, 101 MHz, 300 K): δ = 137.6, 133.1, 131.1, 130.2, 128.4, 128.0, 127.6, 126.5, 124.0, 115.6, 66.80, 49.1. HR-MS/QTOF (+): *m/z* = 344.0657 [M + H]⁺, calculated [C₁₈H₁₉NOBr]⁺ = 344.0650.

Conflicts of interest

There are no conflicts to declare.
