Inorganic planar \(\pi\)-conjugated groups in nonlinear optical crystals: review and outlook

Pifu Gong, Xiaomeng Liu, Lei Kang and Zheshuai Lin

Nonlinear optical (NLO) materials have been playing significant roles in laser science and technology for converting laser wavelengths to spectral regions where normal lasers operated poorly. Inorganic planar \(\pi\)-conjugated groups possessing both large second harmonic generation (SHG) responses and optical anisotropy are one of the most desirable fundamental building units (FBUs) for NLO materials. Up to now, inorganic planar \(\pi\)-conjugated groups including \([\text{BO}_3]\), \([\text{B}_3\text{O}_6]\), \([\text{CO}_3]\), \([\text{NO}_3]\), \([\text{H}_x\text{C}_3\text{N}_3\text{O}_3]\) (\(x\) varying from 0 to 3), \([\text{BS}_3]\), \([\text{B}_3\text{S}_6]\), \([\text{HgSe}_3]\), \([\text{AgSe}_3]\), and \([\text{B}_2\text{P}_5]\) units are reported as NLO-active groups, which strongly enhance the structural diversity of NLO materials. In this review, the NLO materials containing inorganic planar \(\pi\)-conjugated groups are classified according to their shortest transparent regions, i.e. deep-ultraviolet (DUV, \(\lambda < 200\) nm), ultraviolet (UV, \(200\) nm < \(\lambda < 380\) nm), visible (VIS, \(380\) nm < \(\lambda < 780\) nm), and infrared (IR, \(\lambda > 780\) nm) regions. On the basis of available experimental and calculated data, the structure–property relationships and potential applied wave ranges for different inorganic planar \(\pi\)-conjugated groups are discussed.

Introduction

As important photoelectric functional materials, nonlinear optical (NLO) crystals have played unique roles in laser frequency conversion technology, which can efficiently expand the spectral regions of common laser sources.\(^1\) Owing to their excellent performances, NLO crystals in all-solid-state laser systems have been widely applied in industrial processing, semiconductor manufacturing, photolithography, military confrontation, noninvasive medical diagnostics and signal communications.\(^2\)–\(^5\) After making continuous effort for decades, many useful NLO crystals, such as \(\text{KBe}_2\text{BO}_3\text{F}_2\) (KBBF), \(\beta\)-\(\text{BaB}_2\text{O}_4\) (BBO), \(\text{LiB}_3\text{O}_5\) (LBO), \(\text{KTiOPO}_4\) (KTP), \(\text{AgGaS}_2\) (AGS), etc. have been developed and applied for laser frequency conversion in the deep ultraviolet (DUV), ultraviolet (UV), visible (VIS) and infrared (IR) regions.\(^6\)–\(^11\) Meanwhile, great progress has been made on the research of structure–property relationships, which reveal the deterministic effects of the NLO-active units on the NLO performances.\(^12\)–\(^17\)

Pifu Gong received his B.S. in Physics from Shandong Normal University and then obtained his Ph.D. in Condensed Matter Physics from Technical Institute of Physics and Chemistry (TIPC), Chinese Academy of Sciences (CAS) in 2017. His current research focuses on developing new nonlinear-optical materials.

Zheshuai Lin obtained his Ph.D. from Fujian Institute of Research on the Structure of Matter, CAS, in 2002. Since 2008, he has been working as a professor at TIPC, CAS. His research into nonlinear-optical crystals employs a variety of modeling techniques spanning analytical and quantum mechanics.
To realize laser frequency conversion, a NLO crystal must satisfy several fundamental but rigorous requirements, including a wide transparent window for an operating wave range, large second harmonic generation (SHG) response, and sufficient birefringence to achieve phase matching.\(^{16,19}\) All of them are closely related to the fundamental building units (FBUs). On the basis of structure–property relationships, planar $\pi$-conjugated groups, second-order Jahn–Teller (SOJT) distorted [MO$_3$] (M = Ti, Nb, Ta, Mo, W, Te, etc.; Q = O, S, Se, Te) groups, distorted polyhedra centered by stereochemically active long pair (SALP) cations (Pb, Bi, Sb, I, etc.), rare-earth cation centered polyhedra, and metal element centered [MO$_4$] (M = Zn, Al, In, Ga, Ge, etc.; Q = O, S, Se, Te) tetrahedra are regarded as NLO-active units.\(^{20–23}\) Among them, the planar $\pi$-conjugated groups with large SHG responses and optical anisotropy are one of the most desirable FBUs for NLO materials and many materials have achieved practical laser frequency conversion in DUV and UV regions using these groups.

Up to now, the reported planar $\pi$-conjugated NLO-active groups include [BO$_3$], [B$_2$O$_4$], [CO$_3$], [NO$_3$], [H$_2$C$_6$N$_2$O$_7$] ($\chi$ varying from 0 to 3), [BS$_3$], [B$_3$S$_6$], [HgSe$_3$], [AgSe$_3$], and [B$_2$P$_3$] units. [BO$_3$] and [B$_2$O$_4$] possessing $\pi^1$ and $\pi^2$ configurations (where the subscript is the number of atoms constructing the $\pi$-conjugated group and the superscript is the number of $\pi$-electrons constructing the $\pi$-orbitals), respectively, are the most common FBUs for DUV and UV NLO borates. In 2018, Prof. Zhao reviewed the role of cations in [BO$_3$]-based NLO materials and Prof. Pan provided a comprehensive review of fluorooxoborates, which provide a better understanding of the structure–property relationships in NLO borates.\(^{24,21}\) [CO$_3$] ($\pi^1$) and [NO$_3$] ($\pi^3$) have similar structural configurations to [BO$_3$], but provide more $\pi$ electrons on the delocalized $\pi$ orbitals, which results in larger SHG responses. Our group also systematically reviewed the NLO carbonates and nitrates and investigated the relationship between the SHG responses and the arrangements of the planar $\pi$-conjugated NLO-active groups inside.\(^{26–27}\) In 2017, our group pointed out that the [H$_2$C$_6$N$_2$O$_7$] ($\pi^3$) groups could serve as NLO-active units for their similar electronic and structural configuration to the [B$_2$O$_4$] units.\(^{28}\) After that, dozens of hydro-cyanurates and cyanurates are reported, which strongly promote the development of related fields.\(^{29–32}\) Very recently, the no-oxygen-containing planar $\pi$-conjugated units, i.e. [BS$_3$] ($\pi^3$), [B$_2$S$_6$] ($\pi^3$), [HgSe$_3$] ($\pi^2$), [AgSe$_3$] ($\pi^3$), and [B$_2$P$_3$] ($\pi^2$) have been reported as NLO-active units and have attracted much attention in the exploration of related IR NLO materials. All these reported planar $\pi$-conjugated NLO-active groups can achieve both large SHG responses and optical anisotropy, which make them the most desirable FBUs for NLO materials.

Although some reviews have been reported for certain kinds of planar $\pi$-conjugated groups, a systematic review covering all the planar NLO-active groups is absent.\(^{33–36}\) In this work, all the kinds of inorganic planar $\pi$-conjugated groups are covered and the related NLO materials are classified according to their shortest transparent regions, i.e. deep-ultraviolet (DUV, $\lambda < 200$ nm), ultraviolet (UV, 200 nm < $\lambda$ < 380 nm), visible (VIS, 380 nm < $\lambda$ < 780 nm), and infrared (IR, $\lambda > 780$ nm) regions. On the basis of available experimental and calculated data, the potential applied wave ranges for different inorganic planar $\pi$-conjugated groups are investigated. In addition, the structure–property relationships and further developments of the NLO materials containing planar $\pi$-conjugated groups are discussed.

### 2. DUV transparent NLO crystals containing planar $\pi$-conjugated groups

According to our survey, only the NLO materials with [BO$_3$], [B$_2$O$_4$], [CO$_3$] and [NO$_3$] units possess the property of DUV transparency. In this section, the structures and main optical properties of the related DUV transparent NLO crystals are discussed based on their planar $\pi$-conjugated groups.

#### 2.1 DUV transparent borate with planar [BO$_3$] and [B$_2$O$_4$] units

The ABe$_2$BO$_3$F$_2$ (A = Na, K, Rb, Cs, NH$_4$, Tl) family is a classical series of NLO materials. To date, KBe$_2$BO$_3$F$_2$ (KBBF) is still the solo practically usable DUV NLO crystal to generate coherent light shorter than 200 nm by a direct frequency doubling method. This unique ability is attributed to its short UV cutoff edge (146 nm), large SHG coefficient ($d_{11} = 0.47$ pm V$^{-1}$), and moderate birefringence (0.088 at 400 nm). However, KBBF suffers a strong layering growth tendency for the weak F$^-$$^-$$^-$K electrostatic attraction between the adjacent [Be$_2$BO$_3$F$_2$]$_\infty$ layers, which strongly hinders its commercialization. To enhance the interlayer forces, NH$_4^+$ cations are introduced to replace the K$^+$ cations in KBBF. NH$_4$Be$_2$BO$_3$F$_2$ (ABBF) possesses the same structure as KBBF, but introduces the hydrogen bonds between the layers.\(^{37}\) As per analysis, ABBF exhibits comparable optical properties to KBBF, such as a short UV cutoff edge (153 nm), large SHG response (1.2 times that of KH$_2$PO$_4$, i.e. 1.2 × KDP), and moderate birefringence (0.078 at 400 nm). Ultimately, when A-site cations are cut off to overcome the layering tendency of KBBF, γ-Be$_2$BO$_3$F (γ-BBF) was obtained. γ-BBF crystallizes in the non-centrosymmetric (NCS) trigonal space group R32.\(^{37}\) Its powder SHG response is found to be 2.3 times that of KDP. To evaluate its bandgap and birefringence, first-principles calculations are performed and the results reveal that γ-BBF possesses a large bandgap (about 8.56 eV), a moderate birefringence (0.105 at 532 nm), and a large SHG coefficient (d$_{11} = 0.67$ pm V$^{-1}$). According to the refractive index dispersion equations, the calculated shortest phase matching edges for ABBF and γ-BBF are 173.9 nm and 146 nm, respectively. Therefore, both ABBF and γ-BBF can be used as new DUV NLO materials (Fig. 1).

Li$_4$Sr(BO$_3$)$_2$ crystallizes in the monoclinic NCS space group Cc.\(^{38}\) As shown in Fig. 2, its structure is composed of 2D [SrBO$_3$]$_\infty$ layers (Fig. 2b), which are further bridged by [BO$_3$] units to construct the 3D framework of Li$_4$Sr(BO$_3$)$_2$. Based on the grown single crystal (Fig. 2c), the UV cutoff edge is found.
to be 186 nm (corresponding to the bandgap of 6.69 eV). The powder SHG response is found to be 2 times that of KDP. According to the calculated results, Li₄Sr(BO₃)₂ has a large SHG coefficient of 0.64 pm V⁻¹ (d₁₂) and a birefringence of 0.056 (at 532 nm), which agree well with the experimental results. Therefore, Li₄Sr(BO₃)₂ is an attractive candidate for UV NLO applications.

NH₄B₄O₆F is the first member of AB₄O₆F (A = NH₄, Na, K, Rb, Cs) series NLO crystals.³⁹–⁴² The compound crystallizes in the polar NCS space group Pna₂₁. As shown in Fig. 3, three [BO₃] and one [BO₃F] connect together by sharing the O atoms to form the FBU of NH₄B₄O₆F. These FBUs further connect together and construct the 2D [B₄O₆F]∞ layers extended along the a–c plane with the NH₄⁺ cations inserted in the space between the layers. As shown by optical measurements, NH₄B₄O₆F exhibits a wide DUV transparent range down to 156 nm (corresponding to the bandgap of 7.97 eV) and suitable birefringence (0.130 at 407 nm) that enable frequency doubling to 158 nm. The SHG response is found to be 2.5 times that of KDP. The calculated SHG coefficient (d₁₃ = −1.9 pm V⁻¹) and birefringence (0.117 at 1064 nm) show good agreement with the experimental results. All these properties clearly demonstrate that NH₄B₄O₆F is an important NLO crystal for DUV applications.

CsB₄O₆F also belongs to the AB₄O₆F (A = NH₄, Na, K, Rb, Cs) series NLO crystals, but has a different structural type compared to NH₄B₄O₆F.⁴⁰ The compound crystallizes in the NCS space group Pna₂₁. As shown in Fig. 4, the FBU of CsB₄O₆F consists of [B₂O₅] and [BO₃F] units. These FBUs further connect together and construct the 2D [B₄O₆F]∞ layers of CsB₄O₆F. Optical measurements reveal that CsB₄O₆F exhibits a short cutoff edge (155 nm), a large SHG response (1.9 × KDP), and a suitable birefringence (0.127 at 400 nm) that enable frequency doubling down to 171.6 nm. The calculated SHG coefficient (d₁₃ = 0.92 pm V⁻¹) and birefringence (0.114 at 1064 nm) agree well with the experimental results. In addition, CsB₄O₆F possesses a more compact structure compared with KBBF, enabling the facile growth of large single crystals with a better growth habit.

β-BaB₂O₄ (BBO) is a classic NLO crystal and has been widely used for laser frequency conversion.⁴³ BBO crystallizes in the NCS space group R₃c and its structure is shown in Fig. 5, which consists of isolated [B₃O₆] units and Ba cations. BBO possesses a large SHG coefficient of 1.6 pm V⁻¹ (d₂₂) and a large birefringence of 0.125 (at 404 nm) with a UV cutoff edge at 185 nm (corresponding to the bandgap of 6.72 eV). All these
excellent properties guarantee its practical applications as a UV NLO crystal.

2.2 DUV transparent carbonate with planar $[\text{CO}_3]$ units

K$\text{SrCO}_3\text{F}$ belongs to the ABCO$_3$F $(A = \text{K, Rb, Cs}; B = \text{Mg, Ca, Sr, Ba})$ series NLO fluoride carbonates and crystallizes in the NCS space group $P\overline{6}m2$. As shown in Fig. 6, its FBU consists of one $[\text{SrO}_6\text{F}_2]$ polyhedron and three $[\text{CO}_3]$ units, which are connected together to form the 2D $[\text{SrCO}_3]_{\infty}$ layer in the $a\overline{b}$ plane as shown in Fig. 6b. These layers further construct the 3D framework of K$\text{SrCO}_3\text{F}$ by sharing the bridging F atoms with K atoms inserted in the space to balance the charges. Large, centimetre-sized single crystals of K$\text{SrCO}_3\text{F}$ have been grown by top seeded solution growth methods. Based on the obtained crystals, the main optical properties are determined. As per measurements, the UV absorption edge, birefringence and SHG coefficient are 195 nm (corresponding to the bandgap of 6.38 eV), 0.1117 (at 532 nm), and 0.50 pm V$^{-1}$ ($d_{22}$), respectively. Moreover, K$\text{SrCO}_3\text{F}$ possesses a large laser damage threshold (LDT) over 700 MW cm$^{-2}$ under a 6 ns Nd:YAG laser operating at 15 Hz. All these properties indicate that K$\text{SrCO}_3\text{F}$ is an excellent UV NLO material.

Ca$_2$Na$_3$([CO$_3$])$_3$F crystallizes in the NCS space group $Cm$ and its structure is shown in Fig. 7. Interestingly, the structure of Ca$_2$Na$_3$([CO$_3$])$_3$F can be described by the substitution of NLO-active $[\text{BO}_3]$ units for $[\text{CO}_3]$ units from YCa$_4$O(BO$_3$)$_3$, which resulted in an optimal balance among the SHG coefficient, birefringence and UV transparency. As per measurements, Ca$_2$Na$_3$([CO$_3$])$_3$F has a large SHG response of $3 \times$ KDP and a birefringence of 0.082 with the UV absorption edge located at 190 nm (corresponding to the bandgap of 6.53 eV). The calculated largest SHG coefficient and birefringence are about 0.5 pm V$^{-1}$ ($d_{12}$) and 0.072, respectively, which are in good agreement with the experimental results.

2.3 DUV transparent nitrates with planar $[\text{NO}_3]$ units

Ba$_2$(OH)$_3$NO$_3$ possesses a hexagonal NCS space group $P\overline{6}2m$ and its structure is shown in Fig. 8. In this compound, the Ba atoms are 9-fold coordinated with O atoms to form a $[\text{BaO}_3\text{(OH)}_6]$ polyhedron, which is further connected with three $[\text{NO}_3]$ units to construct the 3D framework of Ba$_2$(OH)$_3$NO$_3$. The optical measurements show that Ba$_2$(OH)$_3$NO$_3$ has a large SHG response (about 4 times that of KDP) and a birefringence of 0.080 with the UV absorption edge shorter than 200 nm (corresponding to a bandgap of 6.22 eV). Theoretical calculations reveal that the SHG coefficient and birefringence of Ba$_2$(OH)$_3$NO$_3$ are 2.41 pm V$^{-1}$ and 0.082, respectively. More importantly, Ba$_2$(OH)$_3$NO$_3$ exhibits good water-resistance, making this compound a promising UV NLO material.

Clearly, NLO borates, carbonates, and nitrates can show DUV transparency. For borates, the UV cutoff edges are about 180 nm, and those can be blue-shifted to 150 nm for fluoroxyborates. For carbonates, F ions must be introduced to achieve deep UV transmission. For nitrates, only two compounds, i.e. Ba$_2$(OH)$_3$NO$_3$ and Sr$_2$(OH)$_3$NO$_3$, are DUV transparent, while their UV cutoff edges are close to 200 nm. Currently, only borates can achieve the frequency conversion of DUV lasers, while carbonates and nitrates need to further reduce their phase matching wavelengths.

3. UV transparent NLO crystals containing planar $\pi$-conjugated groups

Besides the oxygen containing planar $\pi$-conjugated groups ($[\text{BO}_3]$, $[\text{B}_2\text{O}_6]$, $[\text{CO}_3]$, $[\text{NO}_3]$, $[\text{H}_4\text{C}_2\text{N}_2\text{O}_7]$), $[\text{BS}_3]$ and $[\text{B}_3\text{S}_6]$ can
also exhibit transparency in the UV region. Meanwhile, the introduction of distorted polyhedra centered by SALP cations, rare-earth cation centered polyhedra, and metal element centered [MQ4] tetrahedra will affect their property of transparency. In this section, the related NLO crystals will be discussed.

3.1 UV transparent cyanurates with planar \([\text{H}_3\text{C}_3\text{N}_3\text{O}_3]\) groups

LiCl\((\text{H}_3\text{C}_3\text{N}_3\text{O}_3)\) crystallizes in the polar NCS space group \(R\overline{3}m\), as shown in Fig. 9.\(^{50,51}\) The structure is characterized by graphite-like quasi-2D infinite layers composed of \([\text{H}_3\text{C}_3\text{N}_3\text{O}_3]\) units connected by a \([\text{LiO}_3\text{Cl}]\) tetrahedron (Fig. 9b and c). Interestingly, all the \([\text{H}_3\text{C}_3\text{N}_3\text{O}_3]\) units are coplanar and parallel to one another, which is favorable for large SHG response. As per theoretical calculations, LiCl\((\text{H}_3\text{C}_3\text{N}_3\text{O}_3)\) possesses a large SHG coefficient \((d_{22} = 4.15 \text{ pm V}^{-1})\) and strong optical anisotropy \((\Delta n = 0.28 \text{ at } 1064 \text{ nm})\) with a short UV transparent edge of 215 nm, thus showing an attractive prospect for future NLO applications in the solar-blind regions.

\(\beta\)-Sr\((\text{C}_3\text{N}_3\text{O}_3)\) crystallizes in the NCS space group \(R\overline{3}c\). Its crystal structure is shown in Fig. 10.\(^{52,53}\) \(\beta\)-Sr\((\text{C}_3\text{N}_3\text{O}_3)\) is isostructural to the famous NLO crystal BBO, in which the \([\text{B}_3\text{O}_6]\) is replaced by \([\text{C}_3\text{N}_3\text{O}_3]\). As per measurements, \(\beta\)-Sr\((\text{C}_3\text{N}_3\text{O}_3)\) has a larger powder SHG response than BBO. To provide a more detailed analysis, first-principles calculations were carried out and the results revealed that the compound has a large SHG coefficient \((d_{22} = 3.93 \text{ pm V}^{-1})\) and birefringence \((0.36 \text{ at } 1064 \text{ nm})\) with a UV cutoff edge of about 223 nm. All these optical properties clearly indicated that \(\beta\)-Sr\((\text{C}_3\text{N}_3\text{O}_3)\) can serve as a UV NLO crystal.

KLi\((\text{H}_3\text{C}_3\text{N}_3\text{O}_3)\cdot\text{H}_2\text{O}\) crystallizes in the NCS space group \(Pna2_1\) and its structure is shown in Fig. 11.\(^{53}\) In this compound, the hydro-isocyanurate \([\text{HC}_3\text{N}_3\text{O}_3]\) units connect with each other through \([\text{LiO}_4]\) to form a 1D chain, which further bridges \([\text{HC}_3\text{N}_3\text{O}_3]\) units to construct an intricate 2D layer as shown in Fig. 11b. As per the determination of optical properties, KLi\((\text{H}_3\text{C}_3\text{N}_3\text{O}_3)\cdot\text{H}_2\text{O}\) shows a large SHG response about 5.3 times that of KDP with a UV cutoff edge of 237 nm (corresponding to the bandgap of 5.23 eV). More importantly, a bulk single crystal with 10 mm × 15 mm × 6 mm in size was obtained. Based on the characterization of the single crystals, KLi\((\text{H}_3\text{C}_3\text{N}_3\text{O}_3)\cdot\text{H}_2\text{O}\) exhibits a high LDT of 4.76 GW cm\(^{-2}\) and a large birefringence of 0.186 at 514 nm, which lead to the shortest phase-matching edge to 246 nm.

3.2 UV transparent borates with planar \([\text{BO}_3]\) units

RbZn\(_2\text{BO}_3\text{Br}_2\) belongs to the \(\text{A}\text{Zn}_2\text{BO}_3\text{X}_2\) \((\text{A} = \text{K, Rb, NH}_4; \text{X} = \text{Cl, Br})\) series NLO materials and only RbZn\(_2\text{BO}_3\text{Br}_2\) is discussed here.\(^{54}\) The framework of RbZn\(_2\text{BO}_3\text{Br}_2\) can be described by the tetrahedron substitution of \([\text{BeO}_3\text{F}]\) for \([\text{ZnO}_3\text{Br}]\) from KBBF as shown in Fig. 12. Optical measurements on RbZn\(_2\text{BO}_3\text{Br}_2\) show that this compound is phase-matchable with powder SHG response about 2.53 times that of KDP and its UV cutoff edge is located at 214 nm, corresponding to the bandgap of 5.79 eV. The first-principles calculations show that its largest SHG coefficient is 0.43 \((d_{11})\) and reveal that the enhanced SHG response originates from the cooperative effect of coparallel \([\text{BO}_3]\) triangles and the distorted \([\text{ZnO}_3\text{Br}]\) tetrahedron. Moreover, this series of compounds exhibit a lighter layered growth habit than KBBF, which is beneficial for the research of crystal growth.

Pb\(_2\text{BO}_3\text{Cl}\) crystallizes in the trigonal polar NCS space group \(P\overline{3}2_1\) and exhibits a 2D layered structure as shown in Fig. 13.\(^{55}\)
Pb₂BO₃Br and Pb₂BO₃I are isomorphic to this compound, which are not discussed here.⁵⁶,⁵⁷ As shown in Fig. 13b, the [BO₃] units are parallelly arranged and connected with a neighbouring [PbO₃] pyramid to construct the 2D infinite [PbBO₃] layers in the a–b plane. Owing to the NLO favourable arrangement of [BO₃], Pb₂BO₃Cl exhibits a large SHG response 9 times that of KDP. It also has a wide transparent window from the UV to mid-IR region with a bandgap of about 3.99 eV. The calculated largest SHG coefficient is about 7.2 pm V⁻¹ (d₁₁), which is larger than the experimental result. Its calculated birefringence is 0.12 at 1064 nm, which is in good agreement with the measured phase-matchability.

Cd₄Y(BO₃)₃ belongs to the Cd₄Re(BO₃)₃ (Re = Y, Gd, Lu) series NLO crystals and crystallizes in the monoclinic NCS space group Cm.⁵⁸ There are three kinds of units ([BO₃], [YO₆], and [CdO₆]) in this compound as shown in Fig. 14. In Cd₄Y(BO₃)₃, these three kinds of units connect together by sharing corners and edges and construct the 3D framework. As per measurements, Cd₄Y(BO₃)₃ has a moderate bandgap of 3.78 eV and a large SHG response 5.2 times that of KDP. Cd₄Y(BO₃)₃ is also phase-matchable and has wide transparent regions ranging from UV to IR. The first-principles calculations also guaranteed the large SHG response of Cd₄Y(BO₃)₃ (the calculated d₁₂ = 4.99 pm V⁻¹).

### 3.3 UV transparent carbonate with planar [CO₃] units

Na₃Y(CO₃)₃ crystallizes in the NCS space group Ama₂ and its structure is shown in Fig. 15.⁵⁹ Its crystal structure can be described as alternate stackings of [Na(CO₃)₂]∞ and [Na₂Y(CO₃)₃]∞ layers parallel to the b–c plane. SHG measurements show that Na₃Y(CO₃)₃ has a large SHG response about 3.57 times that of KDP. It also exhibits wide transparent regions from UV to near IR with short UV cut-off edges at about 220 nm, corresponding to the bandgap of 5.59 eV. Theoretical calculation reveals that its largest SHG coefficient is 1.10 pm V⁻¹ (d₃₂). All the mentioned properties suggest that Na₃Y(CO₃)₃ is a promising UV NLO crystal.

CsPbCO₃F is isostructural to the aforementioned KSrCO₃F. CsPbCO₃F crystallizes in the NCS space group P6₁̅m and its structure is shown in Fig. 16.⁶⁰ As per measurements, CsPbCO₃F exhibits a smaller bandgap of 4.15 eV but a larger SHG response about 13.4 times that of KDP compared with KSrCO₃F. The calculated SHG coefficient is about 5.1 pm V⁻¹ (d₂₂), which agrees well with the experimental result. As per the calculated results, it is the p–π interaction between Pb and [CO₃] that resulted in the extremely large SHG efficiency.
KCdCO$_3$F belongs to the ATCO$_3$F (A = K, Rb; T = Zn, Cd) series NLO crystals and here only KCdCO$_3$F is discussed.\footnote{61} KCdCO$_3$F crystallizes in the NCS space group \(P\bar{6}2\) and its structure is shown in Fig. 17. In KCdCO$_3$F, Cd is 5-fold coordinated with 3 O atoms and 2 F atoms and C atoms connect with O atoms to form [CO$_3$] units. One [CdO$_3$F$_2$] connect with three [CO$_3$] units and construct 2D layers, which are further linked by the bridging-F atoms to form the 3D framework of KCdCO$_3$F. Interestingly, the [CO$_3$] units in a certain layer are parallelly arranged but exhibit a rotation in two neighbouring layers. As per measurements, KCdCO$_3$F possesses a large bandgap of 5.30 eV and a SHG response 4.58 times that of KDP. As per calculations, the SHG coefficient and birefringence are 1.99 pm V$^{-1}$ (\(d_{22}\)) and 0.11 at 1064 nm, respectively.

The ATCO$_3$F series NLO fluoride carbonates enrich the structural diversity of NLO carbonates and show great potential as UV NLO materials.

### 3.4 UV transparent nitrates with planar [NO$_3$] units

Rb$_2$Na(NO$_3$)$_3$ crystallizes in the orthorhombic polar NCS space group \(Pmc\overline{2}\), as shown in Fig. 18.\footnote{62} In this compound, the Na atom is coordinated with 10 oxygen atoms, which are further connected with five [NO$_3$] units to construct the FBUs. These FBUs connect together to form a 1D chain with the Rb atoms located between the chains. Rb$_2$Na(NO$_3$)$_3$ possesses a large bandgap of about 4.74 eV and exhibits a large SHG response 5 times that of KDP. The calculated largest SHG coefficient (\(d_{31}\)) is about 3.48 pm V$^{-1}$, which agrees well with the experimental result.

Bi$_3$TeO$_6$OH(NO$_3$)$_2$ crystallizes in the NCS monoclinic space group \(P_2_1\) and its structure contains three kinds of NLO-active units, i.e. planar [NO$_3$] units, distorted [TeO$_6$] octahedron, and [Bi$_3$O$_6$H] groups with stereochemically active lone pair electrons, as shown in Fig. 19.\footnote{63} In Bi$_3$TeO$_6$OH(NO$_3$)$_2$, the [TeO$_6$] octahedron and [Bi$_3$O$_6$H] groups connect together to construct the 2D layers extended in the \(a\)–\(b\) plane with the [NO$_3$] inserted between the layers. Due to the synergistic effects of these NLO-active units, Bi$_3$TeO$_6$OH(NO$_3$)$_2$ achieved a large SHG response about 3 times that of KDP. The measured bandgap of Bi$_3$TeO$_6$OH(NO$_3$)$_2$ is 3.59 eV, corresponding to the UV cutoff edge of 345 nm. Theoretical calculations reveal that the SHG coefficient and birefringence are \(d_{16} = 1.31\) pm V$^{-1}$ and 0.115 at 1064 nm, respectively. Interestingly, Bi$_3$TeO$_6$OH(NO$_3$)$_2$ is resistant to water, which provided an effective approach for practical nitrate NLO materials with high water-resistance.

### 3.5 UV transparent sulfides with planar [BS$_3$] units

BaB$_2$S$_4$ crystallizes in the polar space group \(Cc\) and its structure is shown in Fig. 20.\footnote{64} In BaB$_2$S$_4$, the planar [BS$_3$] units...
and \([\text{BS}_3]\) tetrahedron are connected with each other by sharing corners to construct 1D infinite zigzag \([\text{BS}_4]\) chains along the c-axis with 8-fold coordinated Ba cations located in the inter-chain. As per measurements, \(\text{Ba}_3\text{S}_4\) exhibits a large bandgap of about 3.55 eV, due to which it can achieve a high LDT value during IR NLO applications, which can be preliminarily proven by powder LDT measurement (265 MW cm\(^{-1}\), 1064 nm, 10 ns, 10HZ). The powder SHG measurements show that the compound has a large SHG response about 0.7 times that of \(\text{AgGaS}_2\) with phase-matchability. The calculated largest SHG coefficient and birefringence are \(d_{12} = 8.22 \text{ pm V}^{-1}\) and 0.11 at 2090 nm, respectively, which agree well with the experimental values. Moreover, \(\text{Ba}_3\text{S}_4\) exhibits good air-stability, indicating its potential to become an IR NLO material.

\(\text{LiBaB}_3\text{S}_6\) crystallizes in the NCS monoclinic space group \(\text{Cc}\) and its structure is shown in Fig. 21. As is shown, \(\text{LiBaB}_3\text{S}_6\) contains \([\text{BS}_3]\) anions formed by three corner-sharing \([\text{BS}_4]\) units with a six-membered \([\text{BS}_3]\) ring inside. The metal cations are located between the anion units with Ba and Li 9- and 4-fold coordinated with sulfur atoms. Theoretical calculations demonstrate that \(\text{LiBaB}_3\text{S}_6\) possesses a large bandgap (3.92 eV), thus indicating a high LDT value for mid-IR NLO applications. The birefringence is 0.343 at 1064 nm, which is favorable for achieving phase-matchability. However, the calculated SHG coefficients are rather small (\(d_{12} = 3.46 \text{ pm V}^{-1}\)) owing to the approximately centrosymmetric arrangement of \([\text{BS}_3]\) units.

As discussed above, the UV cutoff edges of NLO cyanurates are located at about 230 nm, indicating their applications in the solar-blind regions. The introduction of a polyhedron with SOJT and SALP cations will result in the red shift of the cutoff edges for borates, carbonates and nitrates. In addition, alkalis and alkaline-earth metals containing NLO sulphides with \([\text{BS}_4]\) and \([\text{BS}_3]\) groups possess large bandgaps above 3.3 eV, which would lead to a large LDT for IR NLO applications.

4. VIS transparent NLO crystals containing planar \(\pi\)-conjugated groups

\(\text{Ba}_3\text{S}_4\text{BiS}_3\) crystallizes in the NCS space group \(\text{P6}2\text{m}\) and possesses a 0D structure constructed by isolated trigonal planar \([\text{BS}_3]\) units and discrete \([\text{SbS}_3]\) pyramids, as shown in Fig. 22. Based on the experimental measurements, \(\text{Ba}_3\text{S}_4\text{BiS}_3\) possesses a moderate bandgap of about 2.62 eV and is transparent in the range of 2.5–11 \(\mu\)m. The SHG response of \(\text{Ba}_3\text{S}_4\text{BiS}_3\) is three times as large as \(\text{AgGaS}_2\). The calculated largest NLO coefficient \(d_{33}\) is about 2.73 pm V\(^{-1}\) and the calculated birefringence is 0.05, which agree well with the powder SHG measurement.

\(\text{A}_3\text{VO(O}_2\text{)}_2\text{CO}_3\) (\(\text{A} = \text{K, Rb, Cs}\)) is a new series of NLO carbonates. These three compounds are isostructural and crystallize in the NCS space group \(\text{Cm}\). The structures are composed of distorted \([\text{VO(O}_2\text{)}_2\text{CO}_3]\) FBUs and charge balancing A\(^+\) cations as shown in Fig. 23. The measured bandgaps are 2.63 eV, 2.73 eV and 2.81 eV for the K\(_x\), Rb\(_x\), and Cs-containing compounds, respectively. Their powder SHG effects are 21, 20, and 23 times that of KDP, respectively. It should be noted that \(\text{Cs}_2\text{VO(O}_2\text{)}_2\text{CO}_3\) showed the largest SHG response among the reported NLO carbonates. The calculated NLO coefficients and birefringence are listed in Table 1. As the theoretical calculations revealed, the \([\text{O}_2]\) anion groups and \([\text{CO}_3]\) in \([\text{VO(O}_2\text{)}_2\text{CO}_3]\) FBUs have made huge contributions to the NLO effects.

\(\text{Bi}_3\text{TeBO}_9\) crystallizes in the polar hexagonal space group \(\text{P6}_3\) and its structure is shown in Fig. 24. This compound contains three kinds of NLO-active units, i.e. planar \([\text{BO}_3]\) units, a SOJT distorted \([\text{TeO}_6]\) octahedron, and a \([\text{BiO}_6]\) octahedron with stereochemically active lone pair electrons. These units connect with each other by sharing corners and edges to construct the 3D framework of \(\text{Bi}_3\text{TeBO}_9\). Due to the synergistic effects of these units, \(\text{Bi}_3\text{TeBO}_9\) has achieved the largest SHG responses 20 times that of KDP among the ever-reported borate NLO crystals. The bandgap of this compound is found to be 3.23 eV, which is located in the VIS region. In addition, theoretical calculations show that this compound has a larger NLO coefficient \(d_{33}\) of about 5.1 pm V\(^{-1}\) and reveal that such a large SHG response resulted from the synergistic effects of constituted NLO-active groups.

By introducing more than one bandgap-reducing units \([\text{O}_2]\), \([\text{VO}_3]\) polyhedron, \([\text{TeO}_6]\) and \([\text{BiO}_6]\)), the UV transparent edges of borates and carbonates can be red shifted to the VIS region. Meanwhile, owing to the synergistic effects of multiple NLO-active units, the largest SHG responses of both NLO borates and carbonates are achieved, which will promote the exploration of materials with high laser frequency conversion efficiency in the visible spectrum region.

[^a] Calculated results by DFT methods.

5. IR transparent NLO crystals containing planar π-conjugated groups

BaHgSe₂ belongs to the orthorhombic NCS space group Pmc2₁ and its structure is shown in Fig. 25. In its structure, the Hg atoms have two different coordinated environments, where Hg1 atoms are coordinated to three Se atoms to form trigonal planar [HgSe₃⁻] units, while Hg2 atoms are bonded to two Se atoms to construct the [HgSe₂] linear units. The [HgSe₃⁻] units connect with each other by sharing the bridging Se atoms and construct a 1D infinite chain along the a-axis, which will lead to large SHG responses. As per measure-
ments, the bandgap of BaHgSe₂ is about 1.56 eV and its SHG response is about 1.5 times that of AgGeS₂. Moreover, the calculated largest SHG coefficient $d_{33}$ is about 39.87 pm V$^{-1}$ and the birefringence is 0.147 at 2090 nm. BaHgSe₂ also exhibits good physicochemical stability, holding great promise for IR NLO applications.

Ag₆HgSiSe₆ and Ag₆HgGeSe₆ possess similar structures and both of them crystallize in the NCS space group $Pnm2_1$, the FBUs and the structures of which are shown in Fig. 26 and 27, respectively. In Ag₆HgSiSe₆, [Ag/HgSe₃] and [SiSe₄] are connected alternately to form 1D [HgSiSe₅] chains along the $b$-axis, which are further linked with each other’s chains via [AgSe₃] and [AgSe₄] to construct the 3D framework of Ag₆HgSiSe₆. It should be noted that the planar [Ag/HgSe₃] units are aligned completely parallel to each other in the 1D [HgSiSe₅] chains, which would be the main origin of the large SHG responses of Ag₆HgSiSe₆. Ag₆HgGeSe₆ adopts a similar structure to that of Ag₆HgSiSe₆, but its [Ag/HgSe₃] units degenerate into [Ag/HgSe₂], thus reducing the second-order nonlinear polarizability of Ag₆HgGeSe₆. As per the measurements, the bandgaps of Ag₆HgSiSe₆ and Ag₆HgGeSe₆ are 1.00 eV and 0.92 eV, respectively. The measured powder SHG effects of these two compounds are 2 and 0.5 times that of AgGaS₂, which agree well with the calculated SHG coefficients ($d_{12} = 43.22$ pm V$^{-1}$ for Ag₆HgSiSe₆ and $d_{32} = 21.36$ pm V$^{-1}$ for Ag₆HgGeSe₆). The calculated birefringence for Ag₆HgSiSe₆ and Ag₆HgGeSe₆ is 0.233 and 0.207 at 2090 nm, respectively. In addition, these two compounds are congruent-melting. All the mentioned features (such as strong SHG responses, valuable phase-matchable features, and congruent-melting thermal behaviour) make Ag₆HgSiSe₆ and Ag₆HgGeSe₆ promising IR NLO crystals for practical applications.

Na₂BP₂ was obtained by oxidative elimination reactions and it crystallizes in the $Pmc2_1$ space group (Fig. 28). In this compound, the B atoms are three coordinated with P atoms to construct the planar [BP₃] triangles. Every two [BP₃] units are bonded by a corner-sharing P atom and two bridging P atoms to form a [B₂P₅] 5-membered ring. These unique [B₂P₅] FBUs further connect with each other by sharing the exocyclic P atoms and construct a 1D infinite chain. All these chains are arranged along the $a$-axis with an inclined angle of $\sim 90^\circ$ in the $b$-$c$ plane between the adjacent chains. The bandgap of Na₂BP₂ is about 1.10 eV, indicating its shortwave cutoff edge located in the IR regions. Due to the absence of experimental data, the first principles calculations were carried out. As the results revealed, Na₂BP₂ possesses both the largest birefringence ($\Delta n \sim 0.68$) and nonlinearity ($d_{15} \sim 57.14$ pm V$^{-1}$) among all known inorganic NLO materials containing planar NLO-active groups, which make [B₂P₅] a good NLO-active unit and inspire a new direction for designing high-performance NLO materials.

In this section, IR NLO materials with planar [HgSe₃], [AgSe₃], and [B₂P₅] units are discussed. These crystals possess both huge SHG responses and birefringence, which make these units good candidates to achieve high conversion efficiency for IR NLO applications.
summarising the property of transparency, the potential applied wave ranges of various planar π-conjugated groups are evaluated.

In my opinion, inorganic planar NLO-active groups are one of the most desirable FBUs to construct NLO materials. Firstly, they possess large SHG responses and optical anisotropy, which are beneficial for NLO applications. Secondly, their bandgaps cover the whole wave ranges from DUV to IR, indicating that one can find suitable NLO materials with planar NLO-active groups for laser frequency conversion in a certain wave range. However, compared to the oxygen containing planar units, the kinds of no-oxygen containing planar units and the structural diversity of NLO compounds with these units are limited. For further development, NLO materials with new no-oxygen containing planar NLO-active groups should be considered.

6. Conclusions

The main optical properties of the above-mentioned NLO materials containing inorganic planar NLO-active groups are listed in Table 1. All the mentioned NLO crystals exhibit large SHG responses and birefringence, indicating their potential in NLO applications. Specifically, the ordered arrangement of [BO3] units leads to the SHG response about 1.3 times that of KDP (KBBF), which could be enhanced to about 2 × KDP by modifying its density (AB2O3F series), and further enlarged to 20 × KDP (Bi3TeBO9) by introducing other NLO-active units. For NLO carbonates, the SHG responses are about 3 × KDP for the orderly arranged [CO3] units (KSrCO3F), which can further be enlarged to 23 × KDP (Cs3VO(O2)2CO3) by the synergistic effects with other kinds of NLO-active units. For NLO nitrates, the SHG responses are about 5 × KDP for the orderly arranged [NO3] units lead to a response of about 4 × KDP, which is much larger than those of the [BO3] and [CO3] units. For the [H4C3N3O3] units, the SHG responses vary from 5 to 10 times that of KDP, which are dependent on their arrangement and density. For the no-oxygen-containing planar π-conjugated groups, the SHG responses are comparable to or even larger than that of AGS, which is suitable for IR NLO applications. In addition, most of the reported NLO materials containing inorganic planar NLO-active groups are phase-matchable, which indicated sufficient birefringence for practical applications.

To investigate the property of transparency of the planar π-conjugated groups, the distribution plots of the bandgaps of the involved NLO materials are drawn in Fig. 29. As is shown, only the bandgaps of [BO3] and [CO3] can cover the regions from VIS to DUV. [NO3] covers the UV and DUV regions, but its largest bandgap can only touch the DUV region, which makes NLO nitrates not suitable for DUV laser frequency conversion.27,74 The bandgaps of NLO cyanurates are mainly located at about 5.5 eV, which is beneficial for laser frequency conversion in the solar blind region. NLO materials containing [BSi] groups possess bandgaps covering the VIS and UV regions, which would lead to a large LDT for IR NLO applications. For the NLO compounds containing [MSe2] and [B2P3] units, the bandgaps are located in the IR region. Therefore, by
