2.2.2-Cryptand as a bidentate ligand in rare-earth metal chemistry†‡

Amanda B. Chung, † Daniel N. Huh, † Joseph W. Ziller † and William J. Evans †*

The 2.2.2-cryptand ligand (crypt) that is heavily used in reductions of rare-earth metal complexes to encapsulate alkali metal ions has been found to function as a bidentate ligand to rare-earth metal ions in some cases. The X-ray crystal structures of the reduced dinitrogen metal complex, [(R₂N)₂Ce(crypt-x²−O,O)]₂(µ-η²−η²-N₂) (R = SiMe₃), and the ytterbium metallocene, (C₅Me₅)₂Yb(crypt-x²−O,O), are presented to demonstrate this binding mode. The implications of this available binding mode in rare-earth metal cryptand chemistry are discussed.

Introduction

One of the recent advances in rare-earth metal chemistry has been the discovery of crystallographically-characterizable molecular complexes of La(II), Ce(II), Pr(II), Gd(II), Tb(II), Ho(II), Er(II), Lu(II), and Y(II) according to syntheses such as those shown in eqn (1).1

Prior to those discoveries, molecular complexes of +2 lanthanide ions were known only for Eu(II), Yb(II), Sm(II), Tm(II), Dy(II), Er(II), Lu(II), and Y(II) according to syntheses such as those shown in eqn (1).1–9

The 2.2.2-cryptand ligand (crypt) that is heavily used in reductions of rare-earth metal complexes to encapsulate alkali metal ions has been found to function as a bidentate ligand to rare-earth metal ions in some cases. The X-ray crystal structures of the reduced dinitrogen metal complex, [(R₂N)₂Ce(crypt-x²−O,O)]₂(µ-η²−η²-N₂) (R = SiMe₃), and the ytterbium metallocene, (C₅Me₅)₂Yb(crypt-x²−O,O), are presented to demonstrate this binding mode. The implications of this available binding mode in rare-earth metal cryptand chemistry are discussed.
Results and discussion

The first example of a bidentate crypt metal complex of a rare-earth metal ion was discovered while examining the reduction of dinitrogen with Ce(NR2)3 (R = SiMe3) and potassium graphite. Numerous LnA3/M reactions (A = anion; M = alkali metal) of this type have been performed in the past and generated both $(N\equiv N)^2$− and $(N_2)^3$− metal complexes.43–48 For example, crystallographically-characterized examples of $\left[(R_2N)_2(THF)Ln\right]_2(\mu-\eta^2:\eta^2-N_2)$ have been isolated in this way from reactions in THF for the smaller rare-earths, Ln = Nd, Gd, Tb, Dy, Ho, Y, Er, Tm, and Lu, eqn (2).44

Analogous reactions with the larger lanthanides, La, Ce, and Pr, appeared to proceed similarly, but crystallographic confirmation of the products was not obtained. 1H and 15N NMR data on the La product were similar to those on the Y and Lu products.44,46 Hence, it was likely that $(N\equiv N)^2$− products of La, Ce, and Pr formed, but the metal complexes were too sterically unsaturated with these larger metals to crystallize well. Further evidence of reaction in eqn (2) with the large lanthanides was obtained by isolation and crystallographic characterization of the tetrakis(amide) products, $[K(THF)_6][Ln(NR_2)_4]$ for La and Pr and $[Na(THF_4)(Et_2O)][Ce(NR_2)_4]$ for Ce. These tetrakis(amides) can form by complexation to the Ln(NR2)3 starting material of the $(NR_2)^{3−}$ ligands lost by each metal in a successful dinitrogen reduction.44

When the LnA3/M reaction was conducted in Et2O using Ce(NR2)3 and KC8 in the presence of crypt, the $(N\equiv N)^2$− metal complex, $\left[{(R_2N)Ce(crypt-κ^2-O,O')}_2(\mu-\eta^2:\eta^2-N_2)\right]$, 1, was isolated and identified by X-ray diffraction, eqn (3), Fig. 1. This was the first cerium amide $(N\equiv N)^2$− metal complex that could be crystallized.
The crystal structure of 1, shows that it is a neutral metal complex with a side-on bound \((N=\equiv N)^2\) and two amide ligands bound to each cerium. This is similar to the known series of THF adducts in eqn (2), \([[(\text{THF})\{\text{R}_2\text{N}\}_2\text{Ln}\}_2[\mu-\eta^2:\eta^2-\text{N}_2]]\)^44 except instead of one THF molecule per metal, a crypt ligand coordinates to each metal through two oxygen atoms. In this case, crypt is acting as a \(\kappa^2\text{-O,O}^\prime\) “exo-crypt” with binding similar to that of a dimethoxyethane (DME) ligand. Presumably, with the extra steric bulk of crypt versus THF, the Ce \((N=\equiv N)^2\) product is sterically saturated enough to allow isolation and crystallization.

Compound 1 is sparingly soluble in both toluene and benzene. A \(^1\text{H}\) NMR spectrum was taken in both toluene-\(d_8\) and C\(_6\)D\(_6\) (see ESI†). The crypt resonances align with free cryptand in solution and only one resonance is seen for the methyl group of the silyl amides, which is shifted upward.

The 1.233(4) Å N–N distance in 1 is similar to those in the metal complexes in eqn (2), 1.258(3)–1.305(6) Å, and is consistent with a double bond, i.e. \((N=\equiv N)^2\).\(^{49,50}\) The exo-crypt in 1 does not bind symmetrically and has Ce–O distances in 1 of 2.545(2) Å for Ce–O1 and 2.796(2) Å for Ce–O2. In comparison, the Ce–O(THF) distances in the cyclopentadienyl cerium dinitrogen complexes, \([\{\text{C}_5\text{Me}_5\}_2\text{Ce}(\text{THF})\}_2[\mu-\eta^2:\eta^2-\text{N}_2]]\) and \([\{\text{C}_5\text{Me}_5\}_2\text{Ce}(\text{THF})\}_2[\mu-\eta^2:\eta^2-\text{N}_2]\), are 2.607(4) Å and 2.589(3) Å, respectively.\(^{48}\) Hence, the crypt coordination could also be described as a monodentate ligand with a long secondary interaction. The 2.545(2) Å Ce–O(crypt) distance is similar to the 2.518(1) Å Nd–O(THF) distance in \([\{\text{R}_2\text{N}\}_2\text{Nd}(\text{THF})\}_2[\mu-\eta^2:\eta^2-\text{N}_2]\) when the 0.027 Å ionic radius increase from Nd to Ce is considered.\(^{51}\)

Within the coordinated crypt, the 1.437(3)–1.443(3) Å C–O distances involving the coordinating O1 and O2 are within the error limits of the other 1.399(4)–1.424(4) Å C–O distances, as shown in Table 1. The C–C distances and the angles involving the bound oxygen atoms are similar to those in the rest of the crypt molecule.

A second example of exo-crypt coordination was found in the reaction of \((\text{C}_5\text{Me}_5)_2\text{Yb}(\text{BPh}_4)_2\) with crypt in toluene. This reaction was explored to determine if ligand redistribution would occur to form an Yb(\(\equiv\)n)-in-crypt product.\(^{30}\) However, ligand rearrangement occurred to form a bis(cyclopentadienyl) metalocene which crystallized with crypt bound as a bidentate ligand, \((\text{C}_5\text{Me}_5)_2\text{Yb}(\text{crypt-}\kappa^2\text{-O,O}^\prime),\) 2, eqn (4), Fig. 2. The compound was identified by X-ray crystallography, but the data were not of high enough quality for a detailed structural discussion. In the metal complex 2, as in 1, the exo-crypt ligand coordinates like DME. X-ray crystal structures of similar formally eight coordinate \((\text{C}_5\text{Me}_5)_2\text{YbL}_2\) compounds are common with \(L = \text{pyridine}\)\(^{52}\) and with \(L_2 = \text{bipyridine}\) and substituted bipyrindines.\(^{53,54}\)

**Conclusion**

Although 2.2.2-cryptand can stabilize alkali metal ions to generate favorable lattices for crystallization of rare-earth metal complexes and it can encapsulate rare-earth ions as an octadentate ligand, it can also function as a stabilizing bidentate \(\kappa^2\)-chelating ligand for rare-earth metal ions as shown in \([[(\text{R}_2\text{N})_2\text{Ce(crypt-}\kappa^2\text{-O,O}^\prime)]_2[\mu-\eta^2:\eta^2-\text{N}_2]],\) 1, and \((\text{C}_5\text{Me}_5)_2\text{Yb(crypt-}\kappa^2\text{-O,O}^\prime),\) 2. The diverse nature of these two metal complexes suggests that crypt could coordinate to rare-earth metal ions in a variety of different coordination environments.

Similar to these crypt-\(\kappa^2\text{-O,O}^\prime\) binding modes, 18-crown-6 (18-c-6) rare-earth metal complexes are known in which not all
O-donors are coordinated. Two scandium metal complexes containing \(\text{[ScCl}_2(\kappa^2-\text{O,}2\text{-c})\text{]}\] \(X = \text{SbCl}_6\) or \(\text{FeCl}_4\)\(^{35,56}\) and \(\text{[Ce} (\kappa^2-\text{c})\text{]}\text{][N(\text{SiMe}_3)\text{]}\text{]PhF}_4\), \(\text{PhF}_4 = \text{pentafluorophenyl}\)\(^{17}\) have been reported.

To the extent that crypt binds like dimethoxyethane, it constitutes a sterically bulky variation of this commonly-used ether. The size and 3-dimensional nature of crypt means that it can substantially fill the coordination environment of a sterically unsaturated compound. In the case of the \(\text{[L}_2\text{Ln}]_2(\mu-\eta^2:\eta^2-\text{N}_2)\) which crystallizes for smaller metals, Nd–Lu, but not for Ce, it is possible that a single THF ligand was not enough to sterically saturate the coordination environment to yield single crystals for X-ray diffraction. Crypt coordination in 1 led to successful crystallization of this cerium \((N=\text{N}\_2^2)\) compound. Attempts to crystallize \(\text{[(L}_2\text{Ln}]_2(\mu-\eta^2:\eta^2-\text{N}_2))\)'s with DME have been unsuccessful.

The efficacy of crypt in 2 is somewhat different since the \((\text{C}_2\text{Me}_3)_2\text{Yb}\) unit crystallizes in any of the ethers and with one and two coordinating ligands.\(^{32-54,58-60}\) Hence, this is not the case of a sterically unsaturated unit that will not crystallize. The \(\kappa^2\)-crypt just functions as other bidentate coordinating bases.

These results raise interesting possibilities in reaction chemistry. It is possible that crypt can coordinate to a rare-earth metal ion before alkali metal reduction occurs and before the alkali metal cation is formed and inserts into the crypt. Similarly, in the reactions that form Ln-in-crypt \([\text{Ln} (\text{crypt})]^{\text{\lplus}}\) cations,\(^{30,35-37}\) a preliminary step in the procedure could involve bidentate coordination of the crypt to the rare-earth metal ion before it inserts into the cavity. The importance of \(\kappa^2\)-crypt coordination in any reaction coordinate will depend heavily on the specific system, the solvent, and any other ligands present in the reaction mixture. However, in non-polar solvents free of any other coordinating ligands, \(\kappa^2\)-crypt could play an important role as a bidentate ligand that preferentially stabilizes species that are otherwise not isolable.

**Experimental**

All manipulations and syntheses described below were conducted with the rigorous exclusion of air and water using standard Schlenk line and glovebox techniques under an argon or dinitrogen atmosphere. Solvents were sparged with UHP argon and dried by passage through columns containing Q-5 and molecular sieves prior to use. Deuterated NMR solvents were dried over NaK alloy or Na/benzophenone, degassed by three freeze–pump–thaw cycles, and vacuum-transferred before use. \(^1\text{H}\) NMR spectra were recorded on a Bruker AVANCE 600 spectrometer \((\text{H operating at 600 MHz)}\) at 298 K, unless otherwise stated, and referenced internally to residual protio-solvent resonances. 2,2,2-Cryptand (Sigma-Aldrich) was placed under vacuum \((10^{-3} \text{ Torr)}\) before use. Ce\((\text{NR}_3)_3\)\(^{61}\) and \((\text{C}_2\text{Me}_3)_2\text{Yb}\) \((\text{BPh}_4)_6\) were synthesized according to literature procedures.

\(\text{[Ce(NR}_2)_3\text{(crypt-}\kappa^2\text{-O,O')}\text{]}_2(\mu-\eta^2:\eta^2-\text{N}_2)\), 1

A dinitrogen-saturated Et₂O \((3 \text{ mL)}\) solution of Ce\((\text{NR}_2)_3\) \((R = \text{SiMe}_3)\) \((60 \text{ mg, 0.1 mmol)}\) and 2.2.2-cryptand \((36 \text{ mg, 0.1 mmol)}\), chilled to \(-35 \text{ °C},\) was added to a vial containing excess KCl \((20 \text{ mg 0.1 mmol)}\), that had been chilled in a cold well with a liquid nitrogen bath. This generated a yellow solution. Bright yellow crystals were isolated by filtering and placing the Et₂O solution in a \(-35 \text{ °C} \) freezer for several days \((20 \text{ mg, 24%}).\) These were identified as 1 by X-ray diffraction.

\((\text{C}_2\text{Me}_3)_2\text{Yb(crypt-}\kappa^2\text{-O,O')}\), 2

In an argon atmosphere, the addition of a green toluene-solution of \((\text{C}_2\text{Me}_3)_2\text{Yb(BPh}_4)_6\) \((50 \text{ mg, 0.08 mmol)}\) to a toluene \((2 \text{ mL)}\) solution of 2,2,2-cryptand \((30 \text{ mg, 0.08 mmol)}\) generated a green mixture with white precipitate. The mixture was filtered to remove insoluble material and the green solution was layered into hexanes and placed in a \(-35 \text{ °C} \) freezer. After 1 d, green X-ray quality crystals of 2 were formed.
