## Bis-Schiff bases of 2,2'-dibromobenzidine as efficient corrosion inhibitors for mild steel in acidic medium†

Ifzan Arshad, <sup>\*ab</sup> Aamer Saeed, <sup>\*a</sup> Pervaiz Ali Channar, <sup>a</sup> Syeda Aaliya Shehzadi, <sup>ac</sup> Muhammad Naeem Ahmed <sup>d</sup> and Muhammad Siddiq <sup>a</sup>

In this work, three new bis-Schiff bases, namely 1,1'-(2,2'-dibromo-[1,1'-biphenyl]-4,4'-diyl)bis(*N*-phenylmethanimine) (**BNSB01**), 1,1'-(2,2'-dibromo-[1,1'-biphenyl]-4,4'-diyl)bis(*N*-(4-bromophenyl)methanimine) (**BNSB02**) and 4,4'-(2,2'-dibromo-[1,1'-biphenyl]-4,4'-diyl)bis(methanlylidene)bis(azanlylidene) diphenol (**BNSB03**), were synthesized. These Schiff bases were evaluated for their corrosion inhibition ability on mild steel specimens in 0.5 M HCl by using electrochemical and weight loss techniques. The inhibition performance was found to increase with an increase in the inhibitor concentration and decrease with an increase in temperature. The results revealed that the synthesized compounds followed the Langmuir isotherm model and were efficient mixed-type inhibitors. The electrochemical impedance studies also indicated that with a rise in the concentration of inhibitors, the charge transfer resistance increased. The surface morphology of the inhibited and uninhibited specimens was examined using scanning electron microscopy (SEM). The efficiency of the compounds was in the order **BNSB02** > **BNSB03** > **BNSB01**. All the results obtained were in good correlation with each other.

### 1. Introduction

Mild steel is one of the versatile, extensively used and least-expensive materials used in nearly all kinds of industries. One of the principal issues in an industrial process is the inevitable damage of metals and steel due to corrosion, which prompts an upsurge in the manufacturing cost. There are numerous techniques for the control and prevention of corrosion in rough environments.<sup>1–3</sup> Nowadays, a cost-effective method employing organic inhibitors is applied to decrease corrosion attack.<sup>4</sup> Generally, these corrosion inhibitors are used in small quantities. Many investigations<sup>5–8</sup> have proven that nitrogen-, phosphorous-, oxygen-, and sulfur-containing organic compounds are the most effective for this purpose. Their corrosion inhibition activity is generally accredited to their interactions with the metal surface. Usually, the active corrosion sites are blocked by the adsorption of organic compounds on the surface of the metal.

Among the various hetero-atom containing compounds, Schiff bases are quite effective because of the presence of a nitrogen atom, and several such compounds have been reported in the literature as potential corrosion inhibitors for metals and alloys in an acidic medium.<sup>9–13</sup> The growing popularity of Schiff bases as corrosion inhibitors is primarily based on their low toxicity and convenience of synthesis from very inexpensive starting materials.<sup>14,15</sup> Schiff bases are<sup>1,16–21</sup> well-known for their potential for corrosion inhibition, and plentiful research on organic inhibitors has shown that Schiff bases have much greater inhibition efficiencies compared to the analogous aldehydes and amines.

The above considerations encouraged us to evaluate the thermodynamic parameters of the adsorption of three synthesized Schiff bases, namely 1,1'-(2,2'-dibromo-[1,1'-biphenyl]-4,4'-diyl)bis(*N*-phenylmethanimine) (**BNSB01**), 1,1'-(2,2'-dibromo-[1,1'-biphenyl]-4,4'-diyl)bis(*N*-(4-bromophenyl)methanimine) (**BNSB02**) and 4,4'-(2,2'-dibromo-[1,1'-biphenyl]-4,4'-diyl)bis(methanlylidene)bis(azanlylidene) diphenol (**BNSB03**), on the mild steel surface in 0.5 M HCl using weight loss measurements and electrochemical techniques.

### 2. Experimental methods

#### 2.1 Materials and sample preparation

Analytical grade chemicals and solvents were used for the synthesis of the bis-Schiff bases. All the solvents, including benzaldehyde, 4-bromobenzaldehyde, and 4-

Fig. 1 Synthetic route of the Schiff bases BNSB01, BNSB02 and BNSB03.

hydroxybenzaldehyde, were purchased from Sigma Aldrich and used without further purification. GR grade HCl (35%) was obtained from Merck. Mild steel specimens with an elemental composition of C: 0.17%, Si: 0.59%, Mn: 1.6%, P: 0.040% and iron for the rest were used. Specimens of dimensions  $2 \times 2 \times 0.1$  cm were used for all experiments. Before the commencement of electrochemical and gravimetric experiments, the mild steel specimens were polished with emery paper of 600, 800 and 1200 grades under running tap water. These were washed with distilled water, dried with a clean tissue, and finally immersed in benzene and acetone for a few seconds before air drying.<sup>22,23</sup>

## 2.2 Synthesis and characterization data of the corrosion inhibitors

The compound 2,2'-dibromo-4,4'-benzidine (1), as shown in Fig. 1, was synthesized according to a procedure published earlier.<sup>24</sup> The Schiff bases were synthesized by refluxing two moles of benzaldehyde, namely 4-bromobenzaldehyde and 4-hydroxybenzaldehyde, separately with one mole of 2,2'-dibromo-4,4'-benzidine (1) each using ethanol as the solvent for 5 h. The mixture was cooled to room temperature and filtered to obtain the resultant solid, which was further vacuum-dried. The synthetic scheme and molecular structures of the synthesized Schiff bases (BNSB01, BNSB02 and BNSB03) are shown in Fig. 1.

### 2.3 Weight loss measurements

The mild steel specimens were dipped in a solution of 0.5 M HCl with variable amounts of the inhibitors for 4 h in a thermostatically controlled water bath at a constant temperature under aerated conditions, and for comparison purposes, the control was also established. After a specified time interval, these specimens were taken out and rinsed gently with water and acetone until the corrosion products on the specimens were rinsed thoroughly. The average weight loss was calculated by performing a triplicate experiment. The same procedure was repeated for different combinations of temperatures and concentrations of the inhibitors.

### 2.4 Electrochemical measurements

Electrochemical impedance spectroscopy (EIS) and potentiodynamic polarization studies were performed using an electrochemical workstation CHI660D. For this purpose, a conventional cell consisting of three-electrodes, namely a reference electrode (Ag/AgCl), an auxiliary platinum electrode and a working electrode of mild steel with  $1\text{ cm}^2$  area, was used. The electrochemical measurements were performed using all three bis-Schiff base derivatives at  $30^\circ\text{C}$  with variable inhibitor concentrations (0.8–3.2 mM). Potentiodynamic polarization measurements were carried out in the range of  $-850$  to  $-150$  mV at a  $0.4\text{ mV s}^{-1}$  scan rate. Before EIS measurements,

the open circuit potential was stabilized for 30 min. EIS data were recorded between 1 Hz to 100 kHz frequency.

### 2.5 Field emission scanning electron microscopy (FE-SEM)

The surface morphology of the mild steel specimens was studied by using a field emission scanning electron microscope (FE-SEM) Supra 55 (Carl Zeiss, Germany) at a  $10\text{ }\mu\text{m}$  scale with  $1.0\text{k}\times$  magnification. The samples were immersed in 0.5 M HCl, and the effect of different inhibitors along with the control was studied. After 4 h of immersion under optimum conditions, SEM images of both polished mild steel specimens and specimens immersed in 0.5 M HCl in the presence and absence of inhibitors were captured.

## 3. Results and discussion

To synthesize the corrosion inhibitors BNSB01, BNSB02, and BNSB03, the sequence of reactions outlined in Fig. 1 was

followed. First, 1-bromo-3-nitrobenzene was converted to an azoxy compound by reduction, which underwent benzidine rearrangement in the presence of zinc dust to form 2,2'-dibromo-4,4'-benzidine (**1**). The desired Schiff base inhibitors were prepared by the reaction of benzidine (**1**) with benzaldehyde, 4-bromobenzaldehyde and 4-hydroxybenzaldehyde under reflux in ethanol. The synthesized compounds were characterized by NMR (<sup>1</sup>H and <sup>13</sup>C) spectroscopy.

### 3.1 Weight loss measurements

**3.1.1 Effect of inhibitor concentration.** The rate of corrosion ( $C_R$ ) and percentage inhibition efficiency (IE%) of the inhibitors **BNSB01**, **BNSB02**, and **BNSB03** at different concentrations (0.8–3.2 mM) and temperatures (30 to 60 °C) were determined by weight loss measurements, and the data are illustrated in Table 1. The rates of corrosion and inhibition efficiency (%) were determined by using the following eqn (1) and (2).

$$C_R = \frac{\Delta W}{St} \quad (1)$$

where  $S$  is the total exposed area (cm<sup>2</sup>),  $\Delta W$  is the weight loss, and  $t$  is the time of exposure (h) of the specimen.

$$IE\% = \frac{(C_R)_a - (C_R)_p}{(C_R)_a} \times 100 \quad (2)$$

where  $(C_R)_a$ , and  $(C_R)_p$  are the rates of corrosion in the absence and presence of inhibitors, respectively.

The inhibition efficiency increased on increasing the inhibitor concentration, and a decrease in the rate of corrosion was observed at all concentrations (*i.e.* 0.8–3.2 mM), as shown in Table 1. Therefore, it is evident that the inhibition efficiency was concentration dependent. With increasing inhibitor concentration, greater numbers of molecules are adsorbed on the surface of mild steel, which results in increased inhibition efficiency. The adsorbed molecules block the reaction sites and thus protect the metal from corrosion. As the Schiff bases had sufficient available electrons, *i.e.* a lone pair on nitrogen, a lone pair on bromine and the  $\pi$  electrons, which are strongly bonded to the positively-charged metal surface, they could inhibit corrosion. At a concentration of 3.2 mM and 30 °C, **BNSB01**,

	333	0.995	3193.8	-33.45			-33.46

**BNSB02** and **BNSB03** showed the maximum inhibition efficiencies of 85.6%, 90.3% and 87.4%, respectively. Beyond this, no increase in inhibition efficiency was observed with a further increase in inhibitor concentration. The results demonstrated the inhibition efficiencies were in the order **BNSB02 > BNSB03 > BNSB01**. Visual observation before and after the experiment demonstrated that the mild steel specimen almost retained its bright exterior in the presence of inhibitors, whereas the ones immersed into the acid solution did not. This observation endorsed that these inhibitors were highly effective in suppressing corrosion attacks and the rate of corrosion.

**3.1.2 Effect of temperature.** Temperature significantly influences the rate of corrosion, and with rising temperature, the corrosion rates increase exponentially in an acidic medium (hydrogen depolarisation) while the hydrogen evolution overpotential decreases.<sup>25</sup> To comprehend the inhibition efficiency of the Schiff base inhibitors at higher temperatures, their weight loss was measured from 30–60 °C. All the three compounds showed the maximum inhibition efficiency at 30 °C, which steadily decreased with a further rise in temperature. The examined inhibitors showed lower efficiency at higher temperatures because the increase in temperature did not support physical interactions, thus lowering the inhibition efficiency. The adsorption and desorption process at higher temperatures happens after a little time gap, and the duration of exposure of the metal surface to the acidic environment is longer, which lowers the inhibition efficiency.<sup>26</sup>

The relationship of temperature with the rate of corrosion could be given by the Arrhenius type eqn (3):

$$C_R = k \exp\left(-\frac{E_a^*}{RT}\right) \quad (3)$$

An alternative to the Arrhenius equation was

$$C_R = \frac{RT}{Nh} \exp\left(\frac{\Delta S_a^*}{R}\right) \exp\left(-\frac{\Delta H_a^*}{RT}\right) \quad (4)$$

where  $\Delta H_a^*$  is the enthalpy of activation,  $\Delta S_a^*$  is the entropy of activation,  $E_a^*$  is the energy of activation,  $k$  is the Arrhenius pre-exponential factor,  $N$  is Avogadro's number,  $h$  is Planck's constant,  $R$  is the universal gas constant, and  $T$  is the absolute

temperature. The  $E_a^*$  and  $k$  values for mild steel at different concentrations with and without inhibitors were calculated from the values of the slope and intercept of the Arrhenius plots of  $\log C_R$  against  $1/T$  (Fig. 2), respectively, drawn using eqn (3).  $\Delta H_a^*$  and  $\Delta S_a^*$  were calculated from the slope ( $-\Delta H_a^*/R$ ) and intercept [ $\ln(R/Nh) + \Delta S_a^*/R$ ] of the  $\ln C_R/T$  vs.  $1/T$  plots (Fig. S1 in ESI†) drawn using eqn (4). Table 2 presents all the values of  $E_a^*$ ,  $k$ ,  $\Delta H_a^*$  and  $\Delta S_a^*$  for the blank and in the presence of inhibitors.

The activation energy calculations revealed that the value of  $E_a^*$  was higher in the presence of inhibitors compared to that of the blank, which was 32.10 kJ mol<sup>-1</sup>. The higher values of  $E_a^*$  were attributed to the formation of inhibitor-metal complexes in the acidic medium with higher energy barriers.<sup>27</sup> The decrease in the inhibition efficiency with rising temperature was because the  $E_a$  of the inhibitor solution was greater than that of the blank.<sup>28,29</sup> The outcomes of this study rationalize the statement that  $E_a$  increases with an increase in temperature due to the reduction in physisorption.<sup>30</sup> The positive  $\Delta H_a^*$  values in the presence of inhibitors suggested the endothermic dissolution of mild steel, which is a difficult task.<sup>30,31</sup> The value of  $\Delta H_a^*$  in the absence of inhibitors was 29.45 kJ mol<sup>-1</sup>, which was less than the values (40.11–52.93 kJ mol<sup>-1</sup>) calculated in the presence of the three inhibitors.

The large negative values of  $\Delta S_a^*$  in the presence of inhibitors indicated the associative formation of activated complexes. In total, the sum of the increased entropy caused by the desorption of solvent molecules (water) and the decrease in entropy due to the adsorption of organic molecules (solute) is equal to the entropy of activation.<sup>32</sup> In the presence of inhibitors, the activation entropy changes because of the adsorption and desorption process of the inhibitors and water molecules on the surface of steel.<sup>33</sup>

### 3.2 Adsorption isotherms

The interaction between the corrosion inhibitors and steel were best examined by the adsorption isotherms resulting from chemisorption or physisorption. Mainly, the rate of corrosion is affected by the degree of surface coverage of the inhibitors. Therefore, the inhibition efficiency is termed as the function of the electrode surface covered by the molecules of inhibitors.<sup>34</sup>

Fig. 4 Polarisation curves of mild steel in 0.5 M HCl containing different concentrations of (a) BNSB01, (b) BNSB02 and (c) BNSB03.

The concentration and degree of surface coverage ( $\theta$ ) were used to determine the linear relation of the adsorption isotherm ( $\theta = IE (\%) / 100$ ). Various adsorption isotherms, such as Frumkin, Temkin, and Langmuir, were tested for a better understanding of the behavior of the inhibitors, and the Langmuir isotherm model was the best fit.

The relationship between  $\theta$  and  $C$  was given by eqn (5).

$$\frac{C}{\theta} = \frac{1}{K_{\text{ads}}} + C \quad (5)$$

where  $C$  is the inhibitor concentration,  $\theta$  is the covered surface, and  $K_{\text{ads}}$  is the equilibrium constant. When a graph was plotted between  $C$  and  $C/\theta$ , a straight line with a regression coefficient of 0.99 and a slope of 1 was obtained, as shown in Fig. 3. The linear relationship proposes that the inhibitors adsorbed on the mild steel surface obeyed the Langmuir adsorption isotherm and had no interaction with the neighboring sites.<sup>35,36</sup>

$K_{\text{ads}}$  was determined using eqn (5), and the free energy of adsorption was calculated from  $K_{\text{ads}}$  using eqn (6).

$$\Delta G_{\text{ads}}^{\circ} = -RT \ln(55.5K_{\text{ads}}) \quad (6)$$

where  $T$  is the temperature,  $R$  is the universal gas constant, and the concentration of water was 55.5 mol dm<sup>-3</sup>.  $\Delta G_{\text{ads}}^{\circ}$  calculated using eqn (6) was negative and ranged between -30.50 to -34.05 kJ mol<sup>-1</sup>. These values suggested that the adsorption of inhibitors on the surface of the metal was a spontaneous process. Previously, it has been reported that less negative values of  $\Delta G_{\text{ads}}^{\circ}$  (around -20 kJ mol<sup>-1</sup>) indicate adsorption mainly due to electrostatic interactions, and values of  $\Delta G_{\text{ads}}^{\circ}$  around -40 kJ mol<sup>-1</sup> suggest chemisorption. The values of  $\Delta G_{\text{ads}}^{\circ}$  in this study were between -20 kJ mol<sup>-1</sup> and -40 kJ mol<sup>-1</sup>, which suggested both types of adsorptions *i.e.* physisorption and chemisorption.

The enthalpy and entropy of adsorption were calculated using eqn (7):

$$\Delta G_{\text{ads}}^{\circ} = \Delta H_{\text{ads}}^{\circ} - T\Delta S_{\text{ads}}^{\circ} \quad (7)$$

The plot of  $T$  against  $\Delta G_{\text{ads}}^{\circ}$ , exhibited a straight-line with intercept  $\Delta H_{\text{ads}}^{\circ}$  and slope  $-\Delta S_{\text{ads}}^{\circ}$  (Fig. S2†). Table 3 shows the values of the thermodynamic parameters for the three inhibitors. Positive values for the entropy of adsorption indicated that the entropy of the solvent prevailed over the entropy of the solutes. It has also been reported that the type of adsorption can be determined from the value of  $\Delta H_{\text{ads}}^{\circ}$ . If  $\Delta H_{\text{ads}}^{\circ} < 0$ , then it could be physisorption or chemisorption, and if  $\Delta H_{\text{ads}}^{\circ} > 0$ , the type of adsorption is chemisorption.<sup>37</sup> Usually, an enthalpy of adsorption lower than 40 kJ mol<sup>-1</sup> is associated with chemisorption and that higher than 100 kJ mol<sup>-1</sup> is associated with physisorption.<sup>38</sup> For all of these Schiff bases, the enthalpy of adsorption was negative *i.e.* -2.14 to -5.023 kJ mol<sup>-1</sup>, which endorsed the mode to be physisorption.

### 3.3 Potentiodynamic polarization studies

Potentiodynamic polarization studies were carried out for a good understanding of the behavior of the inhibitors in their

**Table 4** Potentiodynamic polarisation parameters for the corrosion of mild steel in 0.5 M HCl in the absence and presence of different concentrations of **BNSB01**, **BNSB02** and **BNSB03** at 303 K

	1.6	464	28.5	9.654	7.696	880.2	85.77
	2.4	489	22.6	10.677	9.243	1002.7	88.67
	3.2	501	17.6	11.398	9.475	1184.9	91.21
<b>BNSB03</b>	0.8	467	60.2	15.481	5.963	336.9	69.92
	1.6	481	46.5	17.545	6.291	392.5	76.77
	2.4	491	34.9	12.863	7.691	606.8	82.58
	3.2	481	29.7	12.281	8.440	707.2	85.17

bias toward the anodic and cathodic reactions. The anodic and the cathodic Tafel curves for **BNSB01**, **BNSB02**, **BNSB03** and blank are presented in Fig. 4. Table 4 shows the parameters of electrochemical corrosion kinetics, *i.e.* Tafel slopes ( $b_a$ ,  $b_c$ ), corrosion potential ( $E_{\text{corr}}$ ), corrosion current density ( $i_{\text{corr}}$ ), and linear polarization

The percentage inhibition efficiency was calculated using eqn (8):

$$\text{IE}(\%) = \frac{i_{\text{corr}}^0 - i_{\text{corr}}}{i_{\text{corr}}^0} \times 100 \quad (8)$$

where  $i_{\text{corr}}^0$  and  $i_{\text{corr}}$  are the corrosion current densities for blank and in the presence of inhibitors, respectively. The corrosion current density for mild steel without any inhibitor was 0.2 mA  $\text{cm}^{-2}$ , which was higher than values recorded in the presence of inhibitors. The decrease in  $i_{\text{corr}}$  value for all three inhibitors indicated that mild steel corrosion was inhibited with an increase in the concentration of the synthesized Schiff bases. Although both cathodic and anodic slopes were displaced in the presence of inhibitors, the cathodic slope showed slightly less displacement compared to the anodic slope. This showed that the kinetics of the dissolution of metal and the evolution of hydrogen changed with the addition of **BNSB01**, **BNSB02**, and **BNSB03**, whereas the reduction of iron was more affected. The values of  $b_c$  and  $b_a$  did not show any regular pattern, which indicated that apart from adsorption, a number of other corrosion-inhibiting mechanisms were taking place.<sup>39</sup> The variation in the values of  $b_a$  and  $b_c$  was also caused by the interference of other species present during inhibitor adsorption.<sup>40</sup> Another reason for this variation might be the lack of a detectable Tafel region. With the addition of an inhibitor, an anodic shift in the equilibrium potential value was observed. Corrosion inhibitors are classified as anodic or cathodic based on whether the shift in  $E_{\text{corr}}$  is more than  $\pm 85$  mV relative to the  $E_{\text{corr}}$  value of the metal in the uninhibited solution.<sup>41</sup> In this study, the shift in the value of  $E_{\text{corr}}$  was less than  $\pm 85$  mV, and hence the synthesized Schiff bases were classified as mixed-type inhibitors. In the uninhibited solution, the value of linear polarisation resistance was 302  $\Omega \text{ cm}^2$ , which was lower than the

values measured in the presence of inhibitors at all concentrations. On increasing the concentration of inhibitors, the value of LPR increased, and the maximum value of 1184.9  $\Omega \text{ cm}^2$  was observed for **BNSB02** when concentration was 3.2 mM.

### 3.4 Electrochemical impedance spectroscopy

The corrosion behavior of mild steel in 0.5 M hydrochloric acid solutions containing different concentrations of Schiff base inhibitors was studied by electrochemical impedance spectroscopy (EIS). The Nyquist plots of mild steel in the acidic solution in the absence and presence of inhibitors consisted of capacitive loops, as presented in Fig. 5. It was observed that the capacitive loops were imperfect semicircles, which might be due to the presence of impurities, inhomogeneity on the surface of the metal in terms of roughness, frequency of dispersion, distribution of surface-active sites and grain boundaries. Therefore, to get a more accurate fit, a constant phase element (CPE) was introduced into the circuit.<sup>42,43</sup> The presence of a single semicircle during the dissolution of metal corresponds to a single charge transfer reaction. For the description of a frequency independent phase shift between an applied ac potential and its current response, a constant phase element (CPE) is used which is defined in impedance representation as in the following equation eqn (9).

$$Z_{\text{CPE}} = Y_0^{-1}(i\omega)^{-n} \quad (9)$$

where  $Y_0$  is the CPE constant,  $\omega$  is the angular frequency (in rad  $\text{s}^{-1}$ ),  $i^2 = -1$  is the imaginary number and  $n$  has the meaning of phase shift.<sup>25</sup> The value of  $n$ , which is the measure of surface inhomogeneity, was found to increase from 0.7 to 0.95 and showed a deviation from the ideal behavior, for which  $n$  is equal to 1. Based on the equivalent circuit shown in Fig. 6, the Nyquist plots were explained to consist of the charge transfer resistance ( $R_{\text{ct}}$ ) connected in parallel to the constant phase element (CPE) and both connected in series with the solution resistance ( $R_s$ ). Table 5 shows the values of all the studied parameters.

Charge transfer resistance and inhibition efficiency are directly related to each other. The value of charge transfer

	1.6	837.2	44.41	3.645	0.8705	75.51
	2.4	1106	20.15	1.205	0.9207	81.46
	3.2	1372	19.32	1.194	0.9211	85.05
BNSB03	0.8	497.2	94.57	7.513	0.8513	58.76
	1.6	501.7	84.87	7.522	0.8633	59.13
	2.4	698.9	76.19	4.645	0.8430	70.66
	3.2	1030	69.64	3.120	0.8533	80.09

resistance  $R_{ct}$  was obtained by the difference between the real impedance at the lower and higher frequencies. Charge transfer resistance increased with an increase in adsorption on the surface of the metal. This was due to the increase in the concentration of the inhibitors, which also corresponded to the increase in the diameter of the semicircle. By using eqn (10), the percentage inhibition efficiency was calculated as:

$$\text{IE}(\%) = \frac{(R_{ct})_p - (R_{ct})_a}{(R_{ct})_p} \times 100 \quad (10)$$

where  $(R_{ct})_a$  and  $(R_{ct})_p$  are the charge transfer resistances of the blank and in the presence of inhibitors, respectively. The value of  $R_{ct}$  increased to 1372  $\Omega \text{ cm}^2$  for BNSB02 at 3.2 mM and 205  $\Omega \text{ cm}^2$  for blank. The values of  $Y_o$  for all the three synthesized Schiff base inhibitors at all concentrations were less compared to the CPE constant  $Y_o$  of the blank, which was 275.60  $\mu\Omega^{-1} \text{ s}^n$ . The decrease in the value of  $Y_o$  on the addition of inhibitors might be due to the desorption of water from the surface of mild steel. This would be followed by adsorption of inhibitor and result in an increase in the double layer thickness due to the Schiff bases on the surface of metal or a decrease in the local dielectric constant. The large values of  $n$  for all the Schiff bases represent reduced inhomogeneity owing to the formation of a protective film.

After immersing mild steel in 0.5 M HCl, Bode plots were recorded for blank and in the presence of inhibitors and are shown in Fig. 7. At higher concentrations of inhibitors, a phase angle shift was observed, which might be due to the protective layer formed on the surface of mild steel that alters the interfacial structure of the electrode.<sup>44</sup> The phase shift was more at higher concentrations because a greater number of Schiff base molecules occupied the large surface area. With increasing concentration, an increase in the value of impedance increased the tendency of current passing through the capacitor.

Fig. 7 Bode plots in the absence and presence of different concentrations of (a) BNSB01, (b) BNSB02 and (c) BNSB03.

#### 4. Mechanism of inhibition

The inhibition efficiency of BNSB01, BNSB02 and BNSB03 on mild steel in 0.5 M HCl can be explained on the basis of molecular size; the modes of interaction of the Schiff bases with

the metal surface include the nature of bonds in the metal along with their capability to produce complexes (chemisorption) and the number of adsorption sites (physisorption). Since all the three Schiff bases have at least two nitrogen atoms, two bromine atoms, and  $\pi$ -electrons, all of these act as adsorption centers.

Fig. 8 Proposed model of adsorption of the synthesized Schiff base inhibitors on mild steel in 0.5 M HCl.

Therefore, inhibitors make coordinate covalent bonds using these electrons and chemisorb onto the surface of mild steel. It is obvious that the protonation of a nitrogen atom is very easy, and it can be physically adsorbed *via* a chloride ion ( $\text{Cl}^-$ ). The large inhibition efficiency of **BNSB02** and **BNSB03** might be due to the presence of the additional electron-releasing bromine ( $\text{Br}^-$ ) and hydroxyl ( $-\text{OH}$ ) groups, respectively. The experimental and quantum chemical calculation studies suggested that the inhibition efficiency of the studied Schiff bases followed the order: **BNSB02** > **BNSB03** > **BNSB01**. The schematic representation of the different modes of adsorption of the most strongly adsorbed Schiff base **BNSB02** on the metal/acid interface is shown in Fig. 8. From the above study, it is obvious that the lone pair electrons of the bromine atoms are donated to the d-orbital of Fe, and therefore, the highest inhibition efficiency is shown by **BNSB02** due to the presence of four bromine atoms. Such donation might cause the build-up of excessive negative charge on the mild steel surface, which facilitates the transfer of electrons from the d-orbitals of the metal to the  $\pi$ -antibonding molecular orbitals of the Schiff bases by retro-donation. These donations and retro-donations support each other through synergy.<sup>45</sup> The lowest inhibition efficiency was exhibited by **BNSB01** compared to the other two inhibitors because **BNSB02** and **BNSB03** possess a bromo substitute on one aryl group and bromo or hydroxy substituents on other the aryl group, while **BNSB01** has no electron releasing groups (Br, OH) on its terminal aryl groups.

## 5. Morphological investigation

To confirm the adsorption of the three inhibitors on the mild steel surface in the presence and absence of inhibitors in 0.5 M

HCl, field emission-scanning electron microscopy (FE-SEM) experiments were carried out. Fig. 9 demonstrates the FE-SEM images of the mild steel surface without and with the acidic solution as well as in the presence of **BNSB01**, **BNSB02** and **BNSB03** at the optimum concentration of 3.2 mM at 30 °C. Fig. 9a is the surface of mild steel before immersion in 0.5 M HCl, while Fig. 9b is the image of the surface after 4 h immersion in the acidic solution. It was clear from the FE-SEM images that the mild steel surface was highly corroded because of the aggressive acidic condition. There were several swollen structures (Fig. 9b), which showed the direct attack of the aggressive acidic ions. However, the images in Fig. 9c–e showed a smooth surface in the presence of inhibitors with no significant change except emery traces, which indicated the high degree of corrosion protection to the mild steel surface offered by the synthesized inhibitors.

## 6. Conclusion

In summary, we demonstrated the synthesis of three bis-Schiff bases **BNSB01**, **BNSB02** and **BNSB03** and examined their potential to act as mixed-type inhibitors. All the tested compounds showed excellent inhibition efficiency for mild steel in 0.5 M HCl. The analysis of weight loss showed that the inhibition efficiency increased with an increase in the concentration of inhibitors and decreased with an increase in temperature. The study of adsorption isotherms and thermodynamic parameters revealed physisorption, and the isotherm was the Langmuir type. Polarisation studies revealed that the inhibitors affected both cathodic, as well as anodic reactions. Electrochemical impedance studies concluded that the large values of charge transfer resistance for the inhibitor solutions

Fig. 9 SEM images of mild Steel after 4 h immersion in 0.5 M HCl at 30 °C: (a) before immersion (polished), (b) with 0.5 M HCl without inhibitor, (c) with 3.2 mM BNSB01, (d) with 3.2 mM BNSB02 and (e) with 3.2 mM BNSB03.

resulted in their higher inhibition efficiency. Further, the SEM images, which illustrated the formation of a protective layer on the surface of mild steel, supported the corrosion inhibition activity of these bis-Schiff bases.
