Effect of NH_3 and HCOOH on the $H_2O_2 + HO \rightarrow HO_2 + H_2O$ reaction in the troposphere: competition between the one-step and stepwise mechanisms†

Tianlei Zhang, *[ac] Mingjie Wen,‡[ac] Zhaopeng Zeng,‡[a] Yousong Lu,‡[b] Yan Wang,‡[a] Wei Wang, [a] Xianzhao Shao,*[a] Zhiyin Wang[a] and Lily Makroni*[b]

The $H_2O_2 + HO \rightarrow HO_2 + H_2O$ reaction is an important reservoir for both radicals of HO and HO_2 catalyzing the destruction of O_3. Here, this reaction assisted by NH_3 and HCOOH catalysts was explored using the CCSD(T)-F12a/cc-pVDZ-F12//M06-2X/aug-cc-pVTZ method and canonical variational transition state theory with small curvature tunneling. Two possible sets of mechanisms, (i) one-step routes and (ii) stepwise processes, are possible. Our results show that in the presence of both NH_3 and HCOOH catalysts under relevant atmospheric temperature, mechanism (i) is favored both energetically and kinetically than the corresponding mechanism (ii). At 298 K, the relative rate for mechanism (i) in the presence of NH_3 (10, 2900 ppbv) and HCOOH (10 ppbv) is respectively 3–5 and 2–4 orders of magnitude lower than that of the water-catalyzed reaction. This is due to a comparatively lower concentration of NH_3 and HCOOH than H_2O which indicates the positive water effect under atmospheric conditions. Although NH_3 and HCOOH catalysts play a negligible role in the reservoir for both radicals of HO and HO_2 catalyzing the destruction of O_3, the current study provides a comprehensive example of how acidic and basic catalysts assisted the gas-phase reactions.

1. Introduction

Hydrogen peroxide (H_2O_2) is of great importance not only because it is involved in various biological and atmospheric processes,[1] but it's also one of the major sources of hydroxyl (HO) and hydroperoxyl (HO_2) radicals which play an important role in combustions and atmospheric chemical processes.[1] Hydroxyl radical (HO) plays an important role in maintaining the balance of atmospheric composition and forming reactive peroxides.[2,3] Also, from the standpoint of degradation ability,[4,5] HO radicals can react with one ozone molecule to produce molecular oxygen and the HO_2 radicals in the upper atmosphere. As an important reaction in HO_x chemistry, the H_2O_2 + HO reaction shown in eqn (1) can determine the consumption of HO radicals in HO_x chain reactions. Meanwhile, this reaction is also an important reservoir[5,6] for both radicals of HO and HO_2 catalyzing the destruction of ozone (O_3).

$$H_2O_2 + HO \rightarrow HO_2 + H_2O \quad (1)$$

It is obvious from previous reports that the H_2O_2 + HO reaction has been extensively studied both experimentally[7–12] and theoretically.[10,13–15] In terms of experiments, for the gas-phase reaction of H_2O_2 + HO, Vakhtin *et al.*[16] obtained its rate coefficient $(1.78 \pm 0.19) \times 10^{-12}$ cm^3 per molecule per s at 296 K through the laser-induced resonance fluorescence technology. Similar to the report of Vakhtin *et al.*,[16] NASA/JPL[17] evaluation suggested the rate coefficient for the H_2O_2 + HO reaction between 200 and 300 K was 1.8×10^{-12} cm^3 per molecule per s. In addition, the results obtained by the experimental group[18,19] revealed that the rate coefficients for the H_2O_2 + HO reaction have positive temperature dependence within different temperature ranges. From the theoretical point of view, Francisco's group[20] has studied the mechanism of H_2O_2 + HO reaction at the CCSD(T)/CBS//MP2/aug-cc-pVDZ level, and their calculated rate coefficient was 1.56×10^{-12} cm^3 per molecule per s at 298 K, which was in good agreement with the experimental results reported by Vaghjiani and coworkers.[10] Then,

a water-assisted H_2O_2 + HO reaction has been reported by Francisco's group. Their calculations show that the rate coefficient for the H_2O_2 + HO reaction with H_2O was 4.09×10^{-12} cm^3 per molecule per s at 298 K, which was 2.6 times larger than the value of the unassisted reaction. Subsequently, the reactions of $H_2O_2\cdots(H_2O)_n$ (n = 1–3) + HO and H_2O_2 + HO$\cdots(H_2O)_n$ (n = 1–3) have been investigated by our group,[21] where the catalytic effect of $(H_2O)_n$ (n = 1–3) is mainly taken from the contribution of H_2O, and in H_2O-assisted reaction, one-step process occurring through cage-like hydrogen bonding network complex and the transition state is kinetically favorable. However, this effort has focused only on the process of H_2O_2 + HO reaction without and with water. As far as we know, the effect of NH_3 and HCOOH on H_2O_2 + HO → HO_2 + H_2O reaction has not been elucidated in the literature yet.

As the most abundant of all alkaline gases, the concentration of NH_3 was found to be 10 ppm in dairy farms and 30 ppb in a polluted ambient atmosphere.[22–25] Meanwhile, NH_3 has similar efficiency as H_2O in catalyzing many hydrogen abstraction reactions.[26–30] Based on the fact that the possibility of the NH_3-catalytic effect on the H_2O_2 + HO → HO_2 + H_2O reaction has been investigated theoretically in this work. Also, owing to the significant abundance of HCOOH in the atmosphere, HCOOH can also be an effective catalyst like H_2O and NH_3. It has been proved in previous investigations that HCOOH can decrease the energy significantly for several atmospheric hydrogen abstraction reactions.[31–37] Thus, it is also necessary to study the possible catalytic effect of HCOOH on the H_2O_2 + HO reaction.

In the present work, the effect of NH_3 and HCOOH on the H_2O_2 + HO → HO_2 + H_2O reaction has been investigated from both energetic and kinetic aspects, which was organized in two ways. Firstly, the roles of NH_3 and HCOOH in the H_2O_2 + HO → HO_2 + H_2O reaction have been studied by both stepwise mechanism and one-step process. Then, the relative impacts of NH_3 and HCOOH and their competition with H_2O have been investigated by considering the dependence of rate coefficient on temperature and catalyst concentrations. Through our research, we expect to provide significant theoretical guidance for further revealing of the H_2O_2 + HO → HO_2 + H_2O reaction assisted by acidic, neutral and basic catalysts in the actual atmospheric environment.

2. Computational methods

2.1 Electronic structure calculation

The electronic structure calculations have been carried out by the Gaussian 09 program.[38] Geometries of all the species including reactants, pre-reactive complexes, transition states, post-reactive complexes, and products were optimized at the M06-2X/aug-cc-pVTZ level. The corresponding frequencies of the optimized geometries were computed at the same level to prove the characteristics of the transition states with one imaginary frequency and the stationary points possess all real frequencies. The minimum energy paths (MEPs) were obtained by intrinsic reaction coordinate (IRC)[39–41] calculations at the same level which confirms TSs, reactants, and products. IRC calculations also confirmed the presence of pre- and post-reactive complexes at the entry and exit site of reaction path.

To improve the accuracy of the energetics, using M06-2X/aug-cc-pVTZ optimized geometries, single-point energy was calculated using ORCA[42] at the CCSD(T)-F12a/cc-pVDZ-F12 level,[43–45] and the scaled ZPEs were added to them. The scaling factor employed to adjust the ZPEs was 0.9490.[46] The reliability of CCSD(T)-F12a/cc-pVDZ-F12 method was further tested by the single point energies of H_2O_2 + HO → HO_2 + H_2O reaction at the W3X-L and W2X[47] using MRCC[48,49] program packages. It is noted that quantitative barrier heights[47,50–53] for complex atmospheric reactions can be obtained using W3X-L, where the accuracy of W2X and W3X-L can respectively reach for the all-electron scalar-relativistic CCSD(T)/CBS and CCSD(Q)/CBS. Here, the calculated results showed that the unsigned error of CCSD(T)-F12a/cc-pVDZ-F12 is less than 0.5 kcal mol^{-1} (Table S1†), when compared with W3X-L results. Therefore, the affordable CCSD(T)-F12a/cc-pVDZ-F12 method is chosen to do single point energy calculations for the H_2O_2 + HO → HO_2 + H_2O reaction assisted by NH_3 and HCOOH.

2.2 Chemical kinetics calculations

H_2O_2 + HO → HO_2 + H_2O reaction assisted by catalyst X (X = NH_3 and HCOOH) can be regarded as a sequential bimolecular reaction shown in eqn (2).

$$\mathrm{HO} + \mathrm{H_2O_2} + \mathrm{X} \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} \mathrm{BC(X\cdots H_2O_2 \text{ or } HO\cdots X)}$$

$$+ \mathrm{HO(or\ H_2O_2)} \underset{k_{-2}}{\overset{k_2}{\rightleftharpoons}} \mathrm{TC(HO\cdots X\cdots H_2O_2)} \xrightarrow{k_{\mathrm{uni}}} \text{products} \quad (2)$$

In eqn (2), the dimer $H_2O_2\cdots$HO is assumed to be less important than $H_2O_2\cdots$X and HO$\cdots$X, due to the small concentration of H_2O_2 and HO radicals. So, the sequential bimolecular route would first occur through the formation of a bimolecular complex BC (X$\cdots H_2O_2$ or HO$\cdots$X), and then bimolecular complex combines with the other reactant (HO or H_2O_2) to form the trimolecular complex TC (HO$\cdots$X$\cdots H_2O_2$). Subsequently, the trimolecular complex undergoes a unimolecular reaction *via* the corresponding TS to form the products. Assuming a steady-state approximation, trimolecular complex TC is in equilibrium with bimolecular complex BC and reactant (H_2O_2 or HO), the bimolecular rate coefficient (k_b) for the reaction between BC and reactant (H_2O_2 or HO) can be written as eqn (3) and calculated by employing Polyrate 8.2 program[54] coupled with the steady-state approximation.

$$k_b = \frac{k_2}{k_{-2} + k_{\mathrm{uni}}} k_{\mathrm{uni}} \quad (3)$$

Here assuming k_{-2} is much larger than k_{uni}, k_b of eqn (3) can be simplified as eqn (4).

$$k_b = K_{eq2} \times k_{\mathrm{uni}} \quad (4)$$

This kinetic model is reasonably correct at the high-pressure limit. In eqn (4), the equilibrium constant K_{eq2} can be written in

eqn (5), while the rate coefficient constant (k_{uni}) from trimolecular complex to the products can be minimized by varying the transition state dividing surface along the reaction coordinate to get the CVT rate coefficients given by eqn (6) and (7):[55–58]

$$K_{eq2}(T) = \sigma \frac{Q_{TC}}{Q_R Q_{BC}} \exp\left(\frac{E_R + E_{BC} - E_{TC}}{RT}\right) \quad (5)$$

$$k^{GT}(T,s) = \Gamma L^{\neq} \times \frac{k_B T}{h} \frac{Q^{\neq}_{TS}(T,s)}{Q_{TC}(T)} \exp\left(-\frac{V_{MEP}(s)}{k_B T}\right) \quad (6)$$

$$k^{CVT}(T) = \min_s k^{GT}(T, \langle s \rangle) = k^{GT}[T, s^{CVT}(T)] \quad (7)$$

where Q_{TC}, Q_{BC} and Q_R in eqn (5) is respectively the total partition function of the trimolecular complex TC, bimolecular complex BC and reactant (HO or H_2O_2); E_{TC}, E_{BC} and E_R is respectively the energy of trimolecular complex TC, bimolecular complex BC and reactant (HO or H_2O_2). $k^{GT}(T,s)$ in eqn (6) and $k^{CVT}(T)$ in eqn (7) is respectively the rate coefficient of generalized and canonical variational transition state theory. Γ is the small curvature tunneling (SCT)[59,60] correction, $L^{\neq}$ is the reaction path degeneracy, h is the Planck's constant, k_B is the Boltzmann constant, $V_{MEP}(s)$ is the classical barrier height and $Q^{\neq}_{TS}$ is the total partition functions for the transition state. It should be noted that K_{eq2} calculated here has been successfully performed in calculating the complexes[61–65] of $H_2O\cdots VOC$, $H_2O\cdots HCHO$, $H_2O\cdots CH_3COCH_3$, $H_2O\cdots CH_2NH$, $H_2O\cdots HO_2$, $H_2O\cdots SO_2$, and $H_2O\cdots NO_2$. In this work, we do not consider the effects of partial pressure on the formation of these complexes because there are no experimental data to show that the equilibrium constants of these complexes are determined by pressure.

The equilibrium constant for the formation of the bimolecular complex (K_{eq1}) can also be calculated using corresponding partition functions and energies (obtained from electronic structure calculations) as eqn (8)

$$K_{eq1}(T) = \sigma \frac{Q_{BC}}{Q_R Q_X} \exp\left(\frac{E_R + E_X - E_{BC}}{RT}\right) \quad (8)$$

where Q_{BC} and Q_R are the total partition functions of the bimolecular complex and reactants, respectively; E_{BC} and E_R are the energies of bimolecular complex and reactants, respectively. From the above, the rate (v) of the sequential bimolecular reaction can be written as:

$$v = K_{eq1} \times K_{eq2} \times k_{uni} \times [X] \times [HO] \times [H_2O_2] \quad (9)$$

Here, v is considered as a measure of the relative efficiencies of the different catalysts under atmospheric conditions.

3. Results and discussions

3.1 Reactants

In the presence of catalyst X, the H_2O_2 + HO + X reaction going through a termolecular reaction has a much lower probability than the sequential bimolecular reaction. In this work, the sequential bimolecular reaction is that, initially, the H_2O_2 + HO + X reaction goes through a two-body complex between catalyst X and one of the two reactants (H_2O_2 or HO) and then the two-body complex will react with the other reactant. It should be noted that, because of the small concentration of H_2O_2 and HO radicals, the concentration of dimer $H_2O_2\cdots HO$ is much lower as compared to the dimers of $H_2O_2\cdots X$ and $HO\cdots X$. Thus, $H_2O_2\cdots HO$ complex can be neglected and it is not taken into account here. Such investigations have been studied in similar investigations,[52,66–70] where the dimer between the two reactants has not been involved in X assisted reactions. Above step is followed since it is very necessary to first identify the stable binary complexes of $H_2O_2\cdots X$ and $HO\cdots X$. To achieve this aim, we performed a stable global minimum searching of geometrical configurations using Tsinghua Global Minimum (TGMin) program[71,72] to search out variety geometrical configurations of $H_2O_2\cdots X$ and $HO\cdots X$ complexes firstly. Secondly initial structures obtained for these binary complexes were selected for geometry optimization using the M06-2X/6-31+G(d,p) level. Then, the structures within 5.0 kcal mol^{-1} of the global minimum were re-optimized by M06-2X/aug-cc-pVTZ level. The optimized structures for the most stable $H_2O_2\cdots X$ and $HO\cdots X$ complexes have been shown in Fig. 1. As displayed in Fig. 1, the stable binary $H_2O_2\cdots NH_3$ complex shows a five-membered ring with two hydrogen bonds (H4$\cdots$N, 1.85 Å; H1$\cdots$O2, 2.67 Å) involved. Its stabilization energy is 6.6 kcal mol^{-1} relative to the separate reactants of H_2O_2 and NH_3, and is respectively stabilized by 1.1 and 6.6 kcal mol^{-1} than the other two binary complexes of $HO\cdots NH_3$ and $NH_3\cdots HO$. Binary complexes of $H_2O_2\cdots HCOOH$ and $HO\cdots HCOOH$ were formed with stabilization energies of 10.1 and 4.9 kcal mol^{-1}, respectively. The energy difference between these two complexes can be explained in terms of ring size formed within their structures. The former complex is formed with a seven-membered ring structure, while the latter complex forms a six-membered ring structure.

3.2 Mechanism and kinetic for NH_3-assisted reaction

Depending on the type of the binary complex discussed above, three different binary mechanisms, labelled as $H_2O_2\cdots NH_3$ + HO, $HO\cdots NH_3$ + H_2O_2, and $NH_3\cdots HO$ + H_2O_2, were obtained (as illustrated in Fig. 2). Among the three NH_3 assisted H_2O_2 + HO $\rightarrow$ HO_2 + H_2O reactions, one proceeds through both one-step and stepwise mechanisms and the other two occur-only through a one-step mechanism. The relative energies to the separate reactants in the presence of NH_3 are given in Table S5.†

As for Channel R_AM1, the reaction starting with $H_2O_2\cdots NH_3$ + HO reactants leads to a termolecular hydrogen bond complex IM_AM1 with a binding energy of 9.5 kcal mol^{-1} relatives to the separate $H_2O_2\cdots NH_3$ + HO reactants. Because of the geometry, additional two hydrogen bonds (N$\cdots$H5, 1.99 Å; O3$\cdots$H1, 2.14 Å) were formed in complex IM_AM1 as compared to $H_2O_2\cdots NH_3$ complex. This leads to complex IM_WM1 shows a quasi-planar cage-like hydrogen bonding network structure. Starting from complex IM_AM1, Channel R_AM1 proceeds through the transition state TS_AM1 where the O atom of HO radical extracts one H atom of H_2O_2 moiety in $H_2O_2\cdots NH_3$ complex. As illustrated in Fig. 2(a), TS_AM1 has a computed

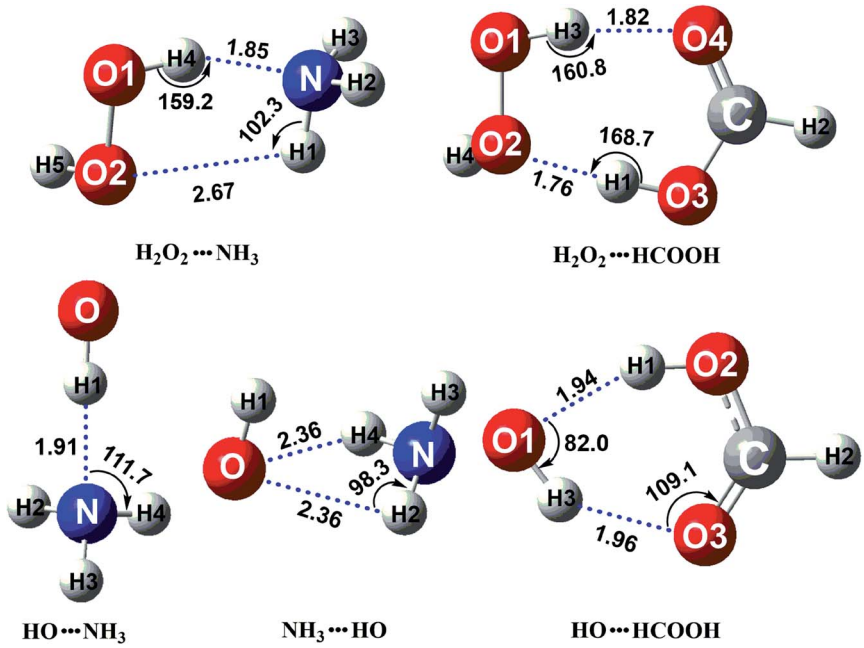

Fig. 1 The optimized structures for the most stable complex of H_2O_2 (or HO) with catalyst X (X = NH_3 and HCOOH) at the CCSD(T)-F12a/cc-pVDZ-F12//M06-2X/aug-cc-pVTZ level.

barrier of 9.2 kcal mol^{-1} relatives to complex IM_AM1. This barrier height is much lower than that for $H_2O_2 + HO \rightarrow HO_2 + H_2O$ reaction without catalyst X, which has an energy barrier of 14.1 kcal mol^{-1} as compared to corresponding pre-reactive complex IM1 (Table S5†). Similarity, compared with the reaction without X, the computed free energy barrier (ΔG, 298 K) of the transition state TS_AM1 to the complex IM_AM1 is reduced to 9.6 kcal mol^{-1} from 14.1 kcal mol^{-1}. Differently from complex IM_AM1 and transition state TS_AM1, post-reactive complex IMF_AM1 shows a planar structure with its stabilization energy of 42.5 kcal mol^{-1} relatives to $H_2O_2\cdots NH_3$ + HO reactants.

As for Channel R_AM2, when NH_3 has introduced into the H_2O_2 + HO → HO_2 + H_2O reaction, two kinds of entrance channels, $H_2O_2\cdots NH_3$ + HO (Path R_AM2a) and $HO\cdots NH_3$ + H_2O_2 (Path R_AM2b), have been displayed in Fig. 2(b). When binary complex $H_2O_2\cdots NH_3$ and HO play as reactants, the reaction occurs in stepwise route, which is similar to H_2O catalyzed reactions[21,28,62,73,74] of HO_2 + HO, HO_2 + HS, H_2O_2 + HO, HO_2 + Cl, and HO_2 + NH_2, as well as NH_3-catalyzed HO_2 + Cl reaction.[28] The first step begins with pre-reactive complex IM_AM2, which transforms into seven-membered ring complex IM_AM3 through transition state TS_AM2 by a ring enlargement. It is noted that complex IM_AM3 has a binding energy of 11.8 kcal mol^{-1}, larger by 5.3 kcal mol^{-1} that of complex IM_AM2. At the same time, the barrier height of the ring enlargement is only 2.6 kcal mol^{-1}, revealing that this elementary step can occur easily both thermodynamically and kinetically. In the second step, the IM_AM3 complex undergoes a direct hydrogen abstraction by the O atom of HO moiety abstracting one H atom of H_2O_2 moiety. This elementary step overcomes a barrier height of 4.4 kcal mol^{-1}, which is higher by 1.8 kcal mol^{-1} than the corresponding barrier height for the step of ring enlargement. This reveals that the second step is the rate-determining step. When $HO\cdots NH_3$ and H_2O_2 act as reactants, the reaction occurs in one elementary step, which is similar to the H_2O_2 + HO → HO_2 + H_2O reaction in the absence of a catalyst. Starting from $HO\cdots NH_3$ + H_2O_2 reactants, Path R_AM2b starts with pre-reactive complex IM_AM3 and proceeds through the transition state TS_AM3 to from the post-reactive complex IMF_AM3, which has been discussed above. To check the competition between $H_2O_2\cdots NH_3$ + HO and $HO\cdots NH_3$ + H_2O_2 in Channel R_AM2, the rate *via* the routes of $H_2O_2\cdots NH_3$ + HO (Path R_AM2a) and $HO\cdots NH_3$ + H_2O_2 (Path R_AM2b) is respectively given in eqn (10) and (11).

$$v_{R\_AM2a} = \frac{d[HO_2]}{dt} = K_{eq1a} \times k_{R\_AM2a} \times [H_2O_2] \times [NH_3] \times [HO] \quad (10)$$

$$v_{R\_AM2b} = \frac{d[HO_2]}{dt} = K_{eq1b} \times k_{R\_AM2b} \times [H_2O_2] \times [NH_3] \times [HO] \quad (11)$$

where K_{eq1a} and K_{eq1b} respectively denote the equilibrium constant for the formation of $H_2O_2\cdots NH_3$ and $HO\cdots NH_3$; k_{R_AM2a} and k_{R_AM2b} respectively denote the bimolecular rate constant of Path R_AM2a and Path R_AM2b. The calculated rate ratio for v_{R_AM2a}/v_{R_AM2b} reveals that the entrance of $HO\cdots NH_3$ and H_2O_2 is more important than that of $H_2O_2\cdots NH_3$ and HO with the ratio of v_{R_AM2a}/v_{R_AM2b} is 5.99 × 10^{-6} to 2.36 × 10^{-5} between 280 and 320 K (Table 1). As a result, Channel R_AM2 occurs mainly through $HO\cdots NH_3$ + H_2O_2 reactants. Similarity, the $NH_3\cdots HO$ + H_2O_2 reaction (Path R_AM3b) only has been taken into account in Channel R_AM3, and the reaction starting

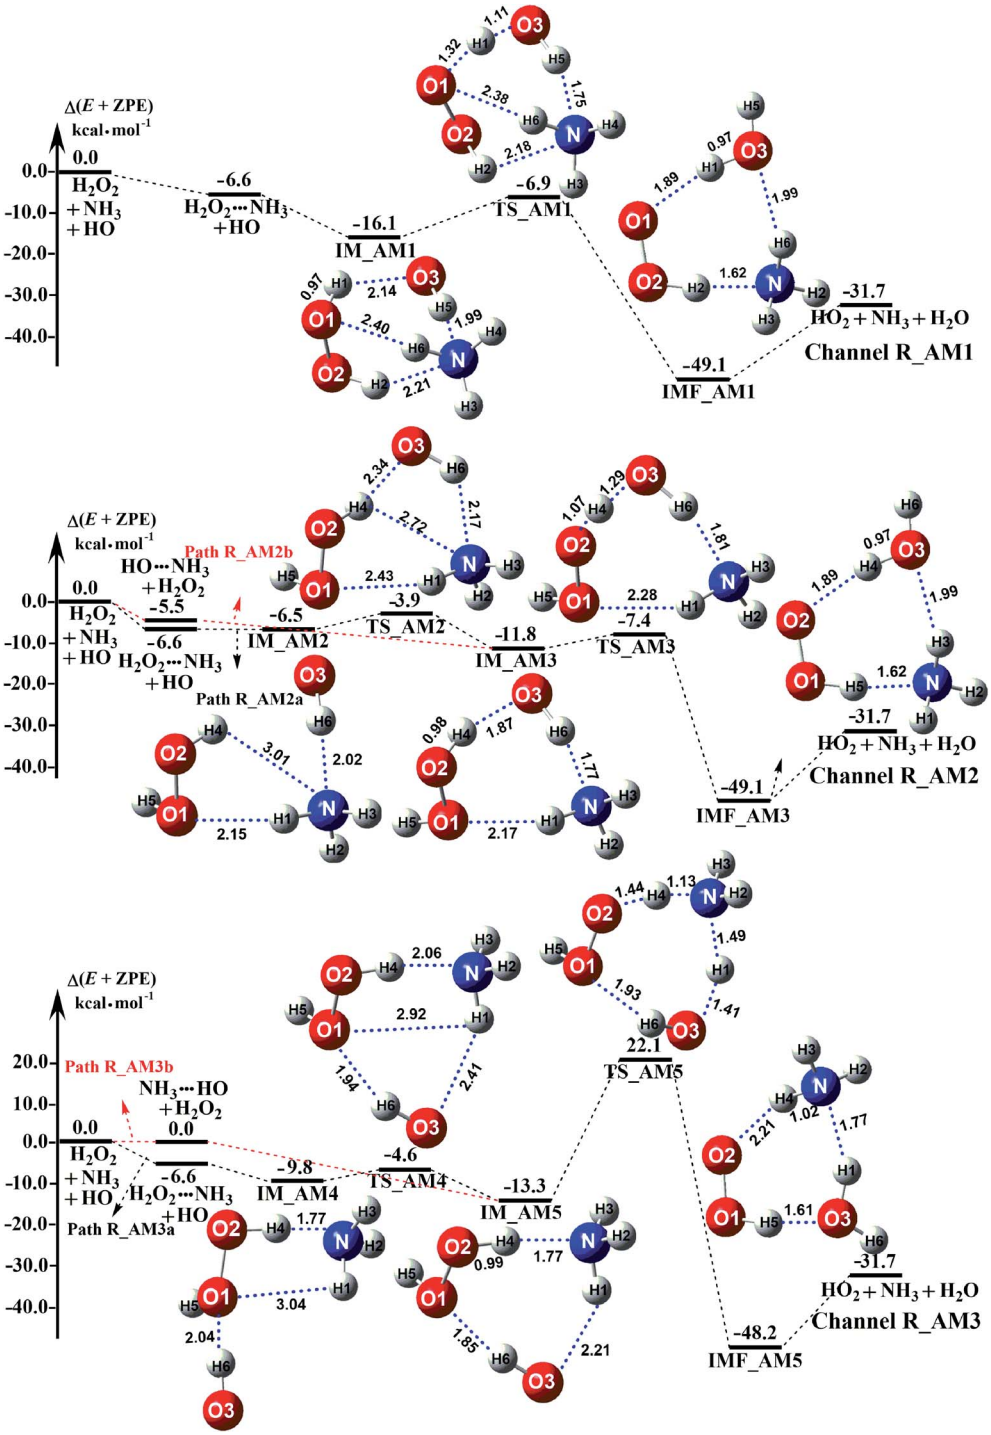

Fig. 2 Schematic potential energy diagrams for NH_3 catalyzed H_2O_2 + HO → HO_2 + H_2O reaction at the CCSD(T)-F12a/cc-pVDZ-F12//M06-2X/aug-cc-pVTZ level.

from $H_2O_2\cdots NH_3$ + HO reactants (Path R_AM3a) has been neglected because the ratio of $\nu_{R\_AM3a}/\nu_{R\_AM3b}$ listed in Table 1 is 3.45×10^{-3} to 7.24×10^{-3} between 280 and 320 K.

Regarding Channel R_AM3 starting from $NH_3\cdots HO$ + H_2O_2 reactants, seven-membered ring complex IM_AM5 proceeded through transition state TS_AM5 to from post-reactive complex IMF_AM5 with the barrier height of 35.4 kcal mol^{-1}. It is noted that the barrier height of Channel R_AM3 is 31.0 kcal mol^{-1} higher than the corresponding barrier height value involved in Channel R_AM2, while the computed free energy barrier (ΔG, 298 K) of Channel R_AM3 is higher by 32.9 kcal mol^{-1} than that of Channel R_AM2. Such energy difference between Channels R_AM2 and R_AM3 is possibly due to that Channel R_AM2 involves a direct hydrogen abstraction, whereas double

Table 1 The bimolecular rate coefficients (cm^3 per molecules per s) and rate ratio for NH_3 catalyzed H_2O_2 + HO → HO_2 + H_2O reaction within the temperature range of 280–320 K

310	8.39×10^{-11}	3.70×10^{-16}	3.06×10^{-11}	1.74×10^{-5}	2.14×10^{-33}	5.81×10^{-28}	6.14×10^{-3}	6.09×10^{19}	3.94
320	7.43×10^{-11}	4.38×10^{-16}	2.55×10^{-11}	2.36×10^{-5}	4.58×10^{-33}	7.69×10^{-28}	7.24×10^{-3}	2.93×10^{19}	4.01

hydrogen transfers were involved in Channel R_AM3. This mechanism discrepancy between Channels R_AM2 and R_AM3 is consistent with water-catalyzed H_2O_2 + HO → HO_2 + H_2O reaction.[21] Hence, double hydrogen transfers mechanisms are considered to be much less probable than the direct hydrogen abstraction mechanism with the mechanism from the IM_AM5 complex being the most unlikely due to the high energy barrier. As a result, the double hydrogen transfer mechanism has not been involved in the HCOOH-catalyzed reaction below. Furthermore, the calculated rate ratio for v_{R_AM1}/v_{R_AM2b} reveals that Channel R_AM1 is more important than that of Channel R_AM2 with the ratio of v_{R_AM1}/v_{R_AM2b} is 3.95–4.01 between 280 and 320 K (Table 1).

3.3 Mechanism and kinetic for HCOOH-assisted reaction

The potential energy surfaces of the reaction channels in the presence of HCOOH for H_2O_2 + H_2O formations occurring through Channels R_FA1 and R_FA2 have been displayed in Fig. 3. As for Channel R_FA1 starting from H_2O_2···HCOOH + HO reactants, the route begins with the formation of the complex IM_FA1. Complex IM_FA1 forms a hydrogen-bonded configuration with a binding energy of 5.9 kcal mol^{-1} as compared to H_2O_2···HCOOH + HO reactants. The structure of IM_FA1 resembles that of H_2O_2···HCOOH complex with additional two hydrogen bonds (H3···O5, 1.98 Å; O1···H4, 1.99 Å) formed between HO and H_2O_2···HCOOH complex. Starting from IM_FA1 complex, the O atom of HO radical directly abstracts the H4 of H_2O_2 moiety in H_2O_2···HCOOH complex, overcoming transition state TS_FA1 with an energy of 0.6 kcal mol^{-1} with respect to H_2O_2···HCOOH + HO reactants. The barrier height of Channel R_FA1 is 6.5 kcal mol^{-1}, which is lower by 7.6 kcal mol^{-1} than the similar route in the absence of a catalyst. Meanwhile, the computed free energy barrier (ΔG, 298 K) is reduced to 7.2 kcal mol^{-1} from 14.1 kcal mol^{-1} in the bare H_2O_2 + HO reaction. This indicates that HCOOH in Channel R_FA1 plays a positive catalytic role in the H_2O_2 + HO → HO_2 + H_2O reaction by reducing the energy barrier.

Because of relative energy, Channel R_FA2 occurring through the H_2O_2···HCOOH + HO reactants is more favorable than that starting from HO···HCOOH + H_2O_2 reactants. Given the relative concentration, the concentration of binary complex of H_2O_2···HCOOH (2.10 molecules per cm^3) is much higher than that of the binary complex of HO···HCOOH (4.17×10^{-5} molecules per cm^3). However, as listed in Table 2, the ratio (v_{R_FA2a}/v_{R_FA2b}) between H_2O_2···HCOOH + HO (Path R_FA2a) and HO···HCOOH + H_2O_2 reaction (Path R_FA2b) in Channel R_FA2 is 0.02–0.03 between 280 and 320 K. The above facts reveal that for Channel R_FA2, the interaction between HO··· HCOOH + H_2O_2 would be more favorable than the action *via* H_2O_2···HCOOH + HO route. As for Path R_FA2b, beginning with the HO···HCOOH + H_2O_2 reactants, the reaction involves the formation of pre-reactive complex IM_FA3 with the binding energy of 11.3 kcal mol^{-1} as compared to HO···HCOOH + H_2O_2 reactants. In the viewpoint of geometrical structure, IM_FA3 shows a nine-membered ring with three hydrogen bonds (H3··· O5, 1.84 Å; O4···H5, 1.79 Å; O2···H1, 1.75 Å) involved. After complex IM_FA3, Path R_FA2 occurs through transition state TS_FA3 where the O atom of HO radical abstracts the H atom of H_2O_2 followed by the elongation of the H5···O4 and H1···O2 bonds respectively by 0.09 Å and 0.11 Å. TS_FA3, as illustrated in Fig. 3, has a computed energy barrier of 8.9 kcal mol^{-1} relatives to complex IM_FA3, lying at 7.3 kcal mol^{-1} below the separate reactants of H_2O_2 + HO + HCOOH. This barrier height is much lower than the H_2O_2 + HO → HO_2 + H_2O reaction, whose energy barrier is determined to be 14.1 kcal mol^{-1}. Similarity, the computed free energy barrier (ΔG, 298 K) is reduced to 8.9 kcal mol^{-1} from 14.1 kcal mol^{-1} in the bare H_2O_2 + HO reaction. This indicates that HCOOH in Channel R_FA2 also plays a positive catalytic role in reducing the energy barrier of the H_2O_2 + HO → HO_2 + H_2O reaction.

As a result of the above, HCOOH-assisted H_2O_2 + HO → HO_2 + H_2O reaction mainly occurs through H_2O_2···HCOOH + HO reaction (Path R_FA1) and HO···HCOOH + H_2O_2 reaction (Path R_FA2b) by one-step route. Moreover, one-step route occurring through HO···HCOOH + H_2O_2 reaction is more competitive than H_2O_2···HCOOH + HO reaction with the ratio of v_{R_FA1}/v_{R_FA2b} is 5.24–3.30 between 280 and 320 K (Table 2).

3.4 Relative impact of NH_3 and HCOOH in troposphere

From the mechanism and kinetic discussed above, X-assisted H_2O_2 + HO → HO_2 + H_2O reaction mainly proceeds through the H_2O_2···X + HO reaction by one-step mechanism. Here, the relative rates for NH_3 and HCOOH to H_2O have been calculated to get a realistic diagram of the relative impact of the NH_3 and HCOOH in the troposphere. To achieve this aim, one-step reaction mechanism of H_2O_2 + HO → HO_2 + H_2O reaction assisted by H_2O at the CCSD(T)-F12a/cc-pVDZ-F12//M06-2X/aug-cc-pVTZ level has been shown in Fig. S1,† while its rate

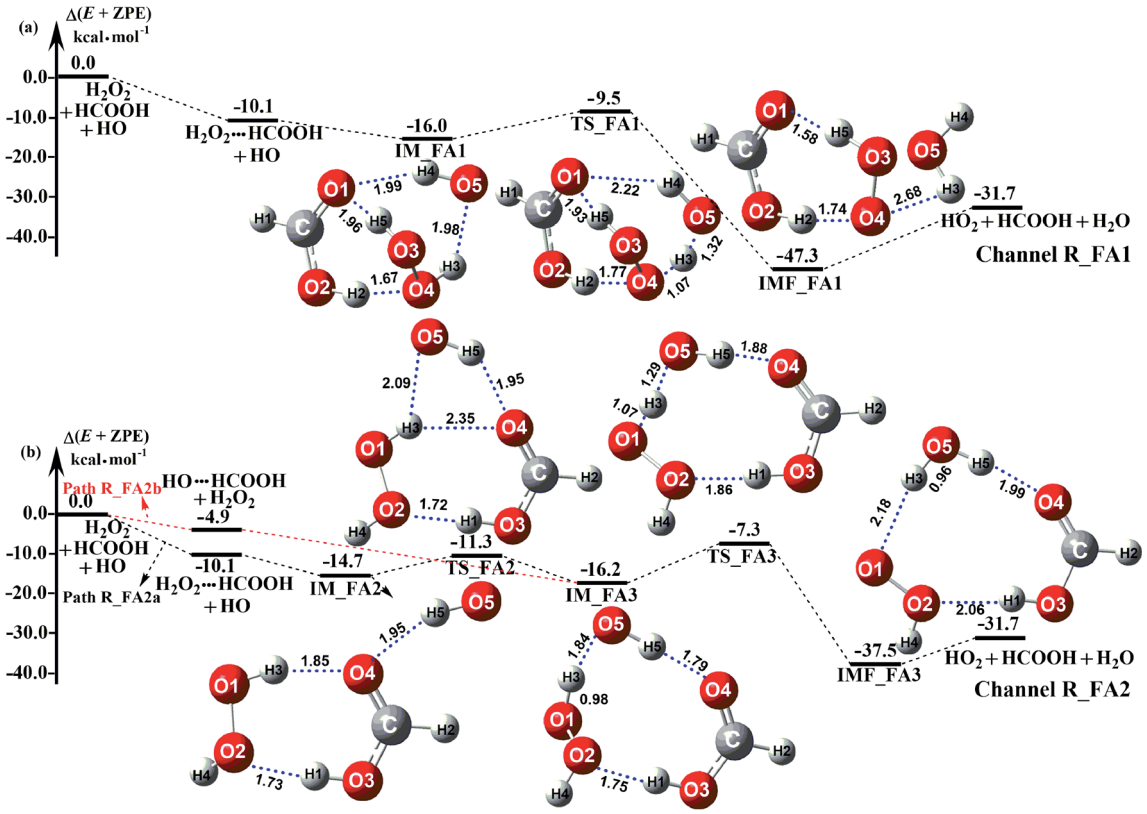

Fig. 3 Schematic potential energy diagrams for favorable channels of HCOOH catalyzed H_2O_2 + HO → HO_2 + H_2O reaction at the CCSD(T)-F12a/cc-pVDZ-F12//M06-2X/aug-cc-pVTZ level.

coefficient within the temperature range of 213–320 K is listed in Table S6.† Thus, the relative rate for NH_3 to H_2O as well as the relative rate for HCOOH as compared to H_2O is respectively given in eqn (12) and (13).

$$\frac{v_{R\_AM}}{v_{R\_WM}} = \frac{K_{eq1a} \times k_{R\_AM1} \times [H_2O_2] \times [NH_3] \times [HO]}{K_{eq1f} \times k_{R\_WM} \times [H_2O_2] \times [H_2O] \times [HO]} = \frac{K_{eq1a} \times k_{R\_AM1} \times [NH_3]}{K_{eq1f} \times k_{R\_WM} \times [H_2O]} \quad (12)$$

$$\frac{v_{R\_FA}}{v_{R\_WM}} = \frac{K_{eq1d} \times k_{R\_FA1} \times [H_2O_2] \times [HCOOH] \times [HO]}{K_{eq1f} \times k_{R\_WM} \times [H_2O_2] \times [H_2O] \times [HO]} = \frac{K_{eq1d} \times k_{R\_FA1} \times [HCOOH]}{K_{eq1f} \times k_{R\_WM} \times [H_2O]} \quad (13)$$

where K_{eq1a}, K_{eq1d}, and K_{eq1f} respectively denote the equilibrium constant for the formation of $H_2O_2\cdots NH_3$, $H_2O_2\cdots HCOOH$ and $H_2O_2\cdots H_2O$; k_{R_AM1}, k_{R_FA1} and k_{R_WM} respectively denote the bimolecular rate coefficient for the favorable one-step mechanism in H_2O_2 + HO → HO_2 + H_2O reaction assisted by NH_3, HCOOH and H_2O. [NH_3], [HCOOH] and [H_2O] are the concentration of NH_3, HCOOH and H_2O, which was obtained from previous report values.[55,64,65,70,75]

The relative rates for v_{R_AM1}/v_{R_WM} and v_{R_FA1}/v_{R_WM} within the temperature range of 280–320 K are given in Table 3. As seen in Table 3, when the concentrations of H_2O at 100% (2.60×10^{17} molecule per cm^3 to 2.30×10^{18} molecule per cm^3)[76] RH and NH_3 at 10 ppbv (2.60×10^{11} molecule per cm^3 to 2.30×10^{11} molecule per cm^3),[22–24] the calculated v_{R_AM1}/v_{R_WM} value is below 2.47×10^{-3} to 9.40×10^{-5} within the temperature range

Table 2 The bimolecular rate coefficients (cm^3 per molecules per s) and rate ratio for HCOOH catalyzed H_2O_2 + HO → HO_2 + H_2O reaction within the temperature range of 280–320 K

T/K	k_{R_FA1}	k_{R_FA2a}	k_{R_FA2b}	v_{R_FA2a}/v_{R_FA2b}	v_{R_FA1}/v_{R_FA2b}
280	9.50×10^{-11}	3.95×10^{-13}	1.86×10^{-8}	0.02	5.24
290	7.32×10^{-11}	3.87×10^{-13}	1.09×10^{-8}	0.02	4.64
298	6.07×10^{-11}	3.82×10^{-13}	7.29×10^{-9}	0.03	4.19
300	5.81×10^{-11}	3.81×10^{-13}	6.64×10^{-9}	0.03	4.10
310	4.67×10^{-11}	3.78×10^{-13}	4.20×10^{-9}	0.03	3.65
320	3.83×10^{-11}	3.79×10^{-13}	2.76×10^{-9}	0.03	3.30

Table 3 The pseudo-first-order rate coefficients (cm^3 per molecules per s) for H_2O, NH_3 and HCOOH catalyzed $H_2O_2 + HO \rightarrow HO_2 + H_2O$ reaction within the temperature range of 280–320 K

T/K	k_t'(R_WM) (100% RH)	k_t'(R_AM1) (10 ppbv)	k_t'(R_AM1) (2900 ppbv)	k_t'(R_FA1) (high 10 ppbv)
280	2.13×10^{-17}	5.25×10^{-20}	1.53×10^{-17}	5.19×10^{-19}
290	3.29×10^{-17}	3.20×10^{-20}	9.35×10^{-18}	2.34×10^{-19}
298	4.63×10^{-17}	2.29×10^{-20}	6.50×10^{-18}	1.27×10^{-19}
300	5.01×10^{-17}	2.02×10^{-20}	5.99×10^{-18}	1.12×10^{-19}
310	7.54×10^{-17}	1.39×10^{-20}	3.99×10^{-18}	5.82×10^{-20}
320	1.01×10^{-16}	9.49×10^{-21}	2.76×10^{-18}	3.07×10^{-20}

T/K	ν_{R_AM1} (10 ppbv)/ν_{R_WM} (100% RH)	ν_{R_AM1} (2900 ppbv)/ν_{R_WM} (100% RH)	ν_{R_FA1} (high)/ν_{R_WM} (100% RH)
280	2.47×10^{-3}	0.72	2.44×10^{-2}
290	9.73×10^{-4}	0.28	7.13×10^{-3}
298	4.94×10^{-4}	0.14	2.75×10^{-3}
300	4.04×10^{-4}	0.12	2.23×10^{-3}
310	1.84×10^{-4}	5.29×10^{-2}	7.72×10^{-4}
320	9.40×10^{-5}	2.74×10^{-2}	3.05×10^{-4}

of 280–320 K. Moreover, when the concentration of NH_3 at 2900 ppbv (7.60×10^{13} molecule per cm^3 to 6.70×10^{13} molecule per cm^3),[25] the calculated ν_{R_AM1}/ν_{R_WM} is still below 0.72–2.74 $\times$ 10^{-2}. This reveals that the $H_2O_2 + HO \rightarrow HO_2 + H_2O$ reaction with NH_3 cannot compete with the reaction in the presence of H_2O. Similarity, when the concentration of HCOOH at 2.60×10^{11} molecule per cm^3 to 2.30×10^{11} molecule per cm^3,[77] the calculated ν_{R_FA1}/ν_{R_WM} value is 2.44×10^{-2} to 3.05×10^{-4} within the temperature range of 280–320 K, indicating that the $H_2O_2 + HO \rightarrow HO_2 + H_2O$ reaction with HCOOH also cannot compete with the corresponding reaction in the presence of H_2O.

4. Summary and conclusions

The effect of catalyst X (X = NH_3 and HCOOH) on the $H_2O_2 + HO \rightarrow HO_2 + H_2O$ reaction was investigated by using quantum chemical calculations and canonical variational transition state theory with small curvature tunneling correction. Two kinds of acid–base catalyzed mechanism, namely one-step route and stepwise processes, were found in the reaction assisted by catalyst X. As for the one-step route, the reaction proceeded through similar direct hydrogen abstraction with the reaction without catalyst X. We found one-step mechanism that is promoted by a low energy barrier, was respectively predicted to take place at a bimolecular rate coefficient of 9.95×10^{-11} cm^3 per molecule per s (NH_3-assisted reaction) and 6.07×10^{-11} cm^3 per molecule per s (HCOOH-assisted reaction) at 298 K, and is very closed to the rate coefficient for the reaction without catalyst X. Stepwise processes here were explored by direct hydrogen abstraction and double hydrogen abstraction transfer mechanism, and were found to be kinetically more favorable *via* direct hydrogen abstraction. However, this hydrogen abstraction in a stepwise route is essentially less important than the hydrogen abstraction in a one-step mechanism.

Within the temperature ranging from 280 K to 320 K, the pseudo-first-order rate coefficient for one-step mechanism in the presence of NH_3 (10 ppbv) and HCOOH (10 ppbv) is only 5.25×10^{-20} to 9.49×10^{-21} cm^3 per molecule per s and 5.19×10^{-19} to 3.07×10^{-20} cm^3 per molecule per s, respectively. This was largely decreased by 3–5 and 2–4 orders of magnitude than the reaction assisted by H_2O in which the positive water effect is significant under atmospheric conditions. This catalytic difference between catalyst X and H_2O is possibly due to a much lower concentration of NH_3 and HCOOH relative to H_2O. Despite the fact that $H_2O_2 + HO \rightarrow HO_2 + H_2O$ reaction with catalyst X is not so efficient to shift the overall $HO_2 + H_2O$ formation rate, the present study provides a comprehensive model of how acidic and basic catalysts assisted the gas-phase reactions.
