1. Introduction

The sulfate salts of general formula $\text{Na}_2\text{M(SO}_4)_2 \cdot n\text{H}_2\text{O}$ ($n = 1, 2,$ 3, 4, 5, 6, 10, 16 ^{$1-14$} have attracted much attention from mineralogists during the last century owing to their important role in desertification, soil contamination and surface and ground water salinization [ref. 13 and references therein]. These natural and synthetic sulfate salts crystallize with a wide range of crystal structure types depending on their degree of hydration. This parameter is at the origin of the presence of unique hydrogen bond features in these compounds. For this reason, numerous studies have focused on solving their crystal structures. In the system with magnesium five phases exist. The blödite-type $\text{Na}_2\text{Mg}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}^8$ and the konyaite-type

Structural and thermal properties of $Na₂Mn(SO₄)₂ · 4H₂O$ and $Na₂Ni(SO₄)₂ · 10H₂O†$

Hamdi Ben Yahia, \mathbf{D}^* a Alaa Alkhateeb^a and Rachid Essehli^b

The title compounds were prepared via a wet chemistry route and their crystal structures were determined from single crystal X-ray diffraction data. N_a Mn(SO₄)₂ · 4H₂O crystallizes with a monoclinic symmetry, space group $P2_1/c$, with $a = 5.5415(2)$, $b = 8.3447(3)$, $c = 11.2281(3)$ \mathring{A} , $\beta = 100.172(1)^\circ$, $V = 511.05(3)$ \mathring{A}^3 and $Z = 2$. Na₂Ni(SO₄)₂.10H₂O also crystallizes with a monoclinic symmetry, space group P2₁/c, with a = 12.5050(8), $b = 6.4812(4)$, $c = 10.0210(6)$ \AA , $\beta = 106.138(2)$ °, $V = 780.17(8)$ \AA ³ and $Z = 2$. $Na₂Mn(SO₄)₂·4H₂O$ is a new member of the blodite family of compounds, whereas Na₂Ni(SO₄)₂·10H₂O is isostructural with $Na₂Mg(SO₄)₂ \cdot 10H₂O$. The structure of $Na₂Mn(SO₄)₂ \cdot 4H₂O$ is built up of $[Mn(SO₄)₂(H₂O)₄]²⁻$ building blocks connected through moderate O–H…O hydrogen bonds with the sodium atoms occupying the large tunnels along the a axis and the manganese atom lying on an inversion center, whereas the structure of Na₂Ni(SO₄)₂·10H₂O is built up of [Ni(H₂O)₆]²⁺ and $[Na_2(SO_4)_2(H_2O)_4]^2$ layers. These layers which are parallel to the (100) plane are interconnected through moderate $O-H\cdots O$ hydrogen bonds. The thermal gravimetric- and the powder X-ray diffractionanalyzes showed that only the nickel phase was almost pure. At a temperature above 300 $^{\circ}$ C, all the water molecules evaporated and a structural phase transition from $P2_1/c$ -Na₂Ni(SO₄)₂.10H₂O to C2/c-Na₂Ni(SO₄)₂ was observed. C2/c-Na₂Ni(SO₄)₂ is thermally more stable than Na₂Fe(SO₄)₂ and therefore it would be suitable as the positive electrode for sodium ion batteries if a stable electrolyte at high voltage is developed.  $Na₂Mg(SO₄)₂·5H₂O⁹$ are both minerals that form due to the evaporation of saline solutions, whereas $\text{Na}_2\text{Mg}(\text{SO}_4)_2 \cdot 10\text{H}_2\text{O}^{13}$ and $\text{Na}_2\text{Mg}(\text{SO}_4)_2 \cdot 16\text{H}_2\text{O}^{14}$ are synthetic phases that were obtained from the evaporation of solutions containing a 1 : 1 molar ratio of MgSO₄ and Na₂SO₄ salts. When the same mixture was heated to 650 °C and slow cooled at a rate of 1° min^{-1} , $Na₂Mg(SO₄)₂$ was obtained.¹⁵ The Na₂M(SO₄)₂ · nH₂O phases are very sensitive to temperature, pressure and relative humidity. When heated at relatively high temperatures (T > 200 °C) these phases could be completely dehydrated to form the $Na₂M(SO₄)₂$ phases which are of interest as positive electrodes for sodiumor lithium-ion batteries.

Among the Na₂M(SO₄)₂ phases, Na₂Fe(SO₄)₂ showed interesting electrochemical properties in Li- and Na-ion batteries. This phase enables the removal of nearly one sodium at potentials around \sim 3.6 V vs. Li⁺/Li or \sim 3.3 V vs. Na⁺/Na.¹⁶ Na₂- $Fe(SO₄)₂$ could also be obtained by intercalating one sodium into the structure of the eldfellite-type $\text{NaFe(SO}_4)_2$ ¹⁷ At 0.1C, this material delivers a discharge capacity of 80 mA h g^{-1} with an operating potential around 3.25 V vs. Na⁺/Na. Even the hydrated phases such as the blödite-type $\text{Na}_2\text{Fe}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}^{16}$ or the kröhnkite-type $\text{Na}_2\text{Fe(SO}_4)_2 \cdot 2\text{H}_2\text{O}^{18}$ were active at \sim 3.3 V and \sim 3.25 V vs. Na⁺/Na, respectively. On the other hand, the $Na₂Co(SO₄)₂$ phase did not show any electrochemical activity up to 5 V.¹⁶ In the system $\text{Na}_2\text{Mn}(\text{SO}_4)_2 \cdot n\text{H}_2\text{O}$ two phases were

reported ($n = 0$ and 2). The thermal decomposition at 500 K of $Na₂Mn_{1.167}(SO₄)₂S_{0.33}O_{1.167}·2H₂O¹⁹$ and the kröhnkite-type $Na₂Mn(SO₄)₂·2H₂O²⁰$ led to the formation of two different $Na₂Mn(SO₄)₂$ phases that crystallize with the glauberite- and alluaudite-type of structures, respectively. The glauberite-type $Na₂Mn(SO₄)₂$ sample was not tested as positive electrode since it contains few $MnS₂O₇$ impurities and the alluaudite-type $Na₂Mn(SO₄)₂$ has shown to be active in sodium ion batteries (NIBs), however the performance was worse than the iron analogues.^{21–23} In the system $\text{Na}_2\text{Ni}(\text{SO}_4)_2 \cdot n\text{H}_2\text{O}$ three phases are known ($n = 0$, 4 and 6), however they were not tested as positive electrode materials for NIBs.²⁴⁻²⁶ For these reasons we prepared recently several $Na₂M(SO₄)₂·nH₂O$ phases (M = Mn and Ni) in order to test their electrochemical performances in NIBs. In this paper we report on the synthesis of the new phases $Na₂Mn(SO₄)₂·4H₂O$ and $Na₂Ni(SO₄)₂·10H₂O$ by wet chemistry route. The crystal structures of these phases were solved using single crystal X-ray diffraction (XRD) and their compositions were confirmed by the combination of thermal gravimetric analyzes (TGA) and energy-dispersive X-ray spectrometry analyzes (EDX). The fully dehydrated phases were analyzed by ex situ powder XRD. Our results are presented in the following sections.

2. Experimental section

2.1. Synthesis

Na₂Mn(SO₄)₂ · 4H₂O powder was synthesized via a wet chemistry route (super-saturation method) from a stoichiometric mixture of Na₂SO₄ (Aldrich, \geq 99%) and MnSO₄·H₂O (Aldrich, \geq 99%). The starting materials with a 1 : 1 molar ratio were dissolved in 20 ml of water (solution A). The solution A was stirred for few hours then left drying at room temperature during four weeks. This enabled the growth of a mixture of large colorless single crystals of $\text{Na}_{12}\text{Mn}_7(\text{SO}_4)_{13} \cdot 15\text{H}_2\text{O}$, $\text{Na}_2\text{Mn}(\text{SO}_4)_2 \cdot 2\text{H}_2\text{O}$ and the new phase $\text{Na}_2\text{Mn}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$. Powder sample of this sample was obtained by grinding few crystals.

 $Na₂Ni(SO₄)₂·10H₂O$ powder was also synthesized via a wet chemistry route (super-saturation method) from a stoichiometric mixture of Na_2SO_4 (Aldrich, \geq 99%) and NiSO₄.6H₂O (Aldrich, \geq 99%). The starting materials with a 1 : 1 molar ratio were dissolved in 20 ml of water (solution B). The solution B was stirred for few hours then left drying at room temperature during three weeks. This enabled the growth of large green single crystals of the new phase $Na₂Ni(SO₄)₂·10H₂O$. Powder sample of this material was obtained by grinding few crystals. The solution B was also dried at 80 $^{\circ}$ C for 12 hours then the resulting powder was grinded and fired at 350 °C for 32 hours. This led to the formation of the green powder of SS-Na₂Ni(SO₄)₂. A similar powder of WC-Na₂Ni $(SO₄)₂$ was obtained when heating under argon the crystals of $\rm Na_2Ni(SO_4)_2 \cdot 10H_2O$ at 400 $^\circ\rm C$ for 6 hours.

2.2. Powder X-ray diffraction measurements

To ensure the purity of the prepared powders, routine powder XRD measurements were performed. The data were collected at

room temperature over the 2 θ angle range of 5[°] $\leq 2\theta \leq 75$ [°] with a step size of 0.01° using a Bruker D8 advance diffractometer operating with CuK α radiation. Full pattern matching refinement was performed with the JANA2006 program package.²⁷ The background was estimated by a Legendre function and the peak shapes were described by a pseudo-Voigt function.

2.3. Single crystal X-ray diffraction measurements

 $Na₂Mn(SO₄)₂·4H₂O$ and $Na₂Ni(SO₄)₂·10H₂O$ single crystals suitable for single crystal X-ray diffraction were selected on the basis of the size and the sharpness of the diffraction spots. The data collections were carried out on a Bruker D8 Venture diffractometer using MoKa radiation. Data processing and all refinements were performed with the APEX3 and JANA2006 program packages, respectively.^{27,28} For the data collection details, see Table 1. Further details on the structure refinements of Na₂Mn(SO₄)₂ · 4H₂O and Na₂Ni(SO₄)₂ · 10H₂O may be obtained from the Fachinformationszentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen (Germany), by quoting the Registry No. CSD – 1962424 and 1962425.

2.4. Electron microprobe analyzes

Semi-quantitative energy-dispersive X-ray spectrometry (EDX) analyzes were carried out on the single crystals used for the data collections with a 7610F (JEOL) scanning electron microscope (SEM). The experimentally observed Na/M/S atomic ratios ($M =$ Mn and Ni) were close to $2:1:2$, as expected for Na₂- $Mn(SO_4)_2 \cdot 4H_2O$ and $Na_2Ni(SO_4)_2 \cdot 10H_2O$.

2.5. Thermal analyzes

Thermal gravimetric analyzes (TGA) were carried out on the prepared samples $Na₂Mn(SO₄)₂·4H₂O$ and $Na₂Ni(SO₄)₂·10H₂O$ using a TA-SDT 650 instrument. The measurements were conducted between 25 and 850 °C at a heating rate of 10 °C min⁻¹. The experiments were performed in alumina crucible under N_2 atmosphere.

3. Results and discussion

3.1. Structure refinement

The systematic absences observed for $\text{Na}_2\text{Mn}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$ and $Na₂Ni(SO₄)₂·10H₂O$ agree with the space group $P2₁/c$. Atomic positions of the majority of atoms were found by the Superflip program implemented in JANA2006 program package.^{27,29} The use of the difference Fourier synthesis allowed us to localize the remaining oxygen atomic positions. With anisotropic atomic displacement parameters (ADPs), the residual factors converged to the value $R(F) = 0.0264$ and $wR(F^2) = 0.0949$ (G.O.F. = 1.92) for 79 refined parameters and 1198 observed reflections for the compound $\text{Na}_2\text{Mn}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$ and $R(F) = 0.0345$ and $\text{wR}(F^2) = 0.0345$ 0.1165 (G.O.F. $= 1.92$) for 106 refined parameters and 2781 observed reflections for the compound $\text{Na}_2\text{Ni}(\text{SO}_4)_2 \cdot 10\text{H}_2\text{O}$. At this stage of the refinements the chemical formulas were $Na₂$ - $Mn(SO_4)_2$ 4O and $Na_2Ni(SO_4)_2$ 10O. The H atomic positions were determined from the difference-Fourier maps. The O–H distances and H-O-H angles were set to 0.96 Å and 104.5°,

Table 1 Crystallographic data and structure refinements for $\text{Na}_2\text{Mn(SO}_4)_{2} \cdot 4H_{2}O$ and $\text{Na}_2\text{Ni(SO}_4)_2 \cdot 10H_{2}O$

respectively. The $U_{\text{iso}}(H)$ were refined without constrains. This led to the final chemical formula $\text{Na}_2\text{Mn}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$ with the residual factors $R(F) = 0.0198$ and $wR(F^2) = 0.0629$ (G.O.F. = 1.22 for 95 refined parameters) and the chemical formula $Na₂$ - $Ni(SO₄)₂·10H₂O$ with the residual factors $R(F) = 0.0251$ and $wR(F^2) = 0.0707$ (G.O.F. $= 1.18$ for 146 refined parameters). By refining the extinction parameters, the residual factors converged to the values given in Table 1. The refined atomic positions and anisotropic ADPs are given in Tables 2 and S1,† respectively. The EDX elemental analyzes performed on the crystals used for the data collection confirmed the compositions $Na₂Mn(SO₄)₂·xH₂O$ and $Na₂Ni(SO₄)₂·xH₂O$ (Fig. 1). The examination of the powder XRD pattern of the manganese sample revealed the presence of mainly $\text{Na}_{12}\text{Mn}_7(\text{SO}_4)_{13} \cdot 15\text{H}_2\text{O}^{30}$ besides a small amount of $Na₂Mn(SO₄)₂·2H₂O²$ and $Na₂$ - $Mn(SO₄)₂·4H₂O$ (Fig. S1†), whereas the nickel sample was almost a pure $\text{Na}_2\text{Ni}(\text{SO}_4)_2 \cdot 10\text{H}_2\text{O}$ phase. Fig. 2 shows a good agreement between the experimental and calculated patterns of $Na₂Ni(SO₄)₂ \cdot 10H₂O$. Evaluation of these data revealed the refined cell parameters $a = 12.4926(5)$, $b = 6.4763(2)$, $c =$ 10.0153(4) Å and $\beta = 106.070(2)^\circ$ which are in good agreement
with those from single graphed differentian data (see Table 1) with those from single crystal diffraction data (see Table 1). Only three tiny impurity peaks were detected. The composition of the $\text{Na}_2\text{Ni}(\text{SO}_4)_2 \cdot 10\text{H}_2\text{O}$ sample was confirmed by the combination of EDX (Fig. 1b) and TGA analyzes.

Fig. 3 clearly indicates a 37.7% of weight loss, which corresponds exactly to the evaporation of ten water molecules. This confirms that the prepared sample $Na_2Ni(SO_4)_2.10H_2O$

decomposes below 300 °C to form WC-Na₂Ni $({\rm SO}_4)_2$ according to the following scheme:

$$
Na_2Ni(SO_4)_2.10H_2O_{(s)} (476.95 g mol^{-1}) \rightarrow WC\text{-}Na_2Ni(SO_4)_{2(s)}
$$

(296.8 g mol⁻¹) + 10H₂O_(g) (180.15 g mol⁻¹)

This decomposition mechanism was confirmed by powder XRD, since the powder pattern of the dehydrated $Na₂Ni(SO₄)₂$ $10H₂O$ phase is identical to the theoretical pattern of Na₂- $Ni(SO_4)_2$ and the experimental pattern of SS-Na₂Ni $(SO_4)_2$ (Fig. 4). Above 700 $^{\circ}$ C, the sample decomposes by releasing $SO_{2(g)}$. It should be noted that the thermal behavior of the sample containing manganese was also performed (Fig. S2†). The weight loss was only 12.9% which is lower than the weight loss of 19.7% expected for $\text{Na}_2\text{Mn}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$, however it is almost identical to the weight loss of 12.4% expected for $Na₁₂$ - $Mn_7(SO_4)_{13} \cdot 15H_2O$. This is in good agreement with PXRD data which indicate that the prepared manganese phase contains mainly the $\text{Na}_{12}\text{Mn}_7(\text{SO}_4)_{13} \cdot 15\text{H}_2\text{O}$ phase.

3.2. Crystal structure of $Na₂Mn(SO₄)₂·4H₂O$

The $\text{Na}_2\text{Mn}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$ compound is isostructural with the blödite-type compounds $Na₂M(SO₄)₂·4H₂O (M = Mg, Fe, Co, Ni,$ Zn, Cd). $31-37$ Conventionally, the blödite-type of structure is described as a stacking of layers parallel to the (010) plane and formed of $MnO_2(H_2O)_4$ and $NaO_4(H_2O)_2$ octahedra (Fig. 5a and b). These layers are interconnected through $SO₄$ tetrahedra to form a 3d-framework (Fig. 5c). The interatomic distances are listed in Table 3.

The manganese atom is lying on an inversion center and is coordinated to two oxygen atoms and four water molecules forming $\mathrm{[MnO_{2}(H_{2}O)_{4}]}^{2-}$ octahedron. This octahedron share corners with two SO_4 tetrahedra forming the building block $\mathrm{[Mn(SO_4)_2 (H_2O)_4]}^{2-}$ (Fig. 5e). The $\mathrm{[MnO_2 (H_2O)_4]}^{2-}$ octahedron share also corners with four $[Na_2O_6(H_2O)_4]^{10-}$ dimer units leading to layers in the (010) plane (Fig. 5a). The $d_{(Mn1-O)}$ distances range from 2.1475 to 2.2088 A with an average distance of 2.1718 \AA which is slightly shorter than the sum of the effective ionic radii of the six-coordinated Mn²⁺ and O^{2-} ${IR}_{(Mn^{2+})}$ + IR_(O²⁻) = 0.83 + 1.4 A^2 .³⁸ The BVS value of 2.14 is in good agreement with the oxidation state 2+ expected for the Mn atoms.³⁹

The slightly distorted SO_4 tetrahedra share only corners with the MnO₂(H₂O)₄ and NaO₄(H₂O)₂ octahedra (Fig. 5c). The $d_{(S1-O)}$ distances range from 1.4565 to 1.4807 A with the average value of 1.4718 A. This value is shorter than the sum of the effective ionic radii of the four-coordinated S^{6+} and $O^{2-}(\text{IR}_{(S^{6+})} + \text{IR}_{(O^{2-})})$

Fig. 1 Images and EDX analyzes of $Na₂Mn(SO₄)₂·4H₂O$ (a) and Na₂- $Ni(SO₄)₂·10H₂O$ (b). These are the single crystals used for the data collections.

In the crystal structure of $Na₂Mn(SO₄)₂·4H₂O$, the H₂O molecules play the role of hydrogen-bond donors whereas the oxygen atoms O3 and O4 are the hydrogen bond acceptors (Table 4 and Fig. 6). The O-H \cdots O hydrogen bonds connect the $\mathrm{[Mn(SO_4)_2(H_2O)_4]}^{2-}$ building blocks (Fig. 5e) forming a tunnellike structure with large voids along the a axis (Fig. 6a). In these voids, the sodium atoms are located (Fig. 5d and 6a). This feature indicates that the compounds of the blödite-family might be good ionic conductors. This may explain the electrochemical activity of the $Na₂Fe(SO₄)₂·4H₂O$ phase in NIBs and LIBs.¹⁶ Based on the classification of Jeffrey, all the O–H \cdots O hydrogen bonds are moderate (Table 4 and Fig. 6b and c).^{40,41}

It is very interesting to notice that the manganese phases $Na₂Mn(SO₄)₂·4H₂O$ [this work], $Na₂Mn(SO₄)₂·2H₂O₂²⁰ Na_{2+\gamma}$ $Mn_{1-\gamma/2}(SO_4)_{32}^{20}$ $Na_{12}Mn_7(SO_4)_{12}[S_2O_7] \cdot 12H_2O^{19}$ and Na_{22} $Mn(SO₄)₂$ ¹⁹ that crystallize with the blödite-, kröhnkite-, alluaudite-, löweite- and glauberite-type of structures, respectively were prepared via a supersaturation method at different temperatures and using the same precursors ($Na₂SO₄ + MnSO₄ \cdot H₂O +$ $H₂O$). At 25 and 70 °C, pure kröhnkite- and löweite-phases were formed, respectively whereas at 22 °C a mixture of kröhnkite-, blödite- and löweite-phases was observed. Furthermore, the thermal treatment of the kröhnkite-phase at 227 °C, led to the formation of an alluaudite-phase with the composition Na_{2+r} $Mn_{1-\gamma/2}(SO_4)_{3}^{20}$ A similar phase could also be prepared *via* a solid state synthesis route when a mixture of $Na₂SO₄$ and $MnSO₄$ was

Fig. 2 Theoretical and experimental powder X-ray diffraction patterns of Na₂Ni(SO₄)₂·10H₂O (Cu-Ka radiation). Asterisk (*) corresponds to an unidentified impurity.

Fig. 3 TGA thermal analysis of the $Na_2Ni(SO_4)_2.10H_2O$ sample.

ball milled then annealed at 350 $^{\circ}$ C for few hours.⁴² Moreover, at 227 °C the löweite-phase decomposed into the glauberite-phase $Na₂Mn(SO₄)₂$ besides an impurity that could be $MnS₂O₇$.¹⁹ Although, the five phases were prepared from the same precursors, their crystal structures are different (Fig. 7). Indeed, the thermal treatments affected significantly the coordination sphere of the Mn atoms. In the blödite-Na₂Mn(SO₄)₂ · $4H_2O$, the Mn atom is coordinated to two oxygen atoms and four water molecules forming the $\text{[MnO}_2(\text{H}_2\text{O})_4]^{\text{2-}}$ octahedron. This octahedron share two corners with the SO_4 tetrahedra to form the $[Mn(SO_4)_2]$ $H_2O)_4$ ²⁻ building block (Fig. 7a). In the kröhnkite-Na₂Mn(SO₄)₂- \cdot 2H₂O, the Mn atom is coordinated to four oxygen atoms and two water molecules. The MnO_6 octahedra share corners with four SO₄ tetrahedra to form infinite chains along the c axis (Fig. 7b). These chains are condensed at 227 \degree C to form the 3d-framework of the alluaudite-Na_{2+ γ}Mn_{1- γ /2}(SO₄)₃. In this structure the MnO₆ octahedra share edges and form dimer units that are interconnected through SO₄ tetrahedra (Fig. 7c). In the löweite-Na₁₂Mn₇(SO₄)₁₂[- S_2O_7 12H₂O, two Mn atoms exist. Mn1 is coordinated to two water molecules and four oxygen atoms, whereas Mn2 is coordinated to six oxygen atoms. The $Mn1O₆$ and $Mn2O₆$ octahedra are bridged by the SO4 tetrahedra to form a 3d-framework (Fig. 7d). At 227 °C, the water molecules of the löweite evaporated and

Fig. 4 Theoretical and experimental powder X-ray diffraction patterns of Na₂Ni(SO₄)₂ (Cu-Ka radiation). SS-Na₂Ni(SO₄)₂ was obtained using solid state synthesis method, whereas WC-Na₂Ni(SO₄)₂ corresponds to the dehydration of Na₂Ni(SO₄)₂·10H₂O obtained using wet chemistry route.

Fig. 5 View along the a and b axes of the layers of MnO₂(H₂O)₄ and NaO₄(H₂O)₂ octahedra (a and b), and projection view of the crystal structure of Na₂Mn(SO₄)₂·4H₂O in the (010) plane (c). View along the a axis of the crystal structure of Na₂Mn(SO₄)₂·4H₂O (d). The atoms of the asymmetric unit are labeled (d). View of the building block [Mn(SO₄)₂(H₂O)₄]^{2–} (e) and the [Na₂O₆(H₂O)₄]^{10–} dimer units (f).

a structural transition to the glauberite-Na₂Mn(SO₄)₂ was observed. In this structure the $MnO₆$ octahedra share corners with six SO_4 tetrahedra to form a 3d-framework (Fig. 7e).

3.3. Crystal structure of $Na₂Ni(SO₄)₂·10H₂O$

The Na₂Ni(SO₄)₂ \cdot 10H₂O compound is isostructural with Na₂- $\rm{Mg(SO_4)_2 \cdot 10H_2O.^{12}}$ The structure is built up of $\rm{[Ni(H_2O)_6]}^{2+}$ and $\left[\textrm{Na}_2(\textrm{SO}_4)_2(\textrm{H}_2\textrm{O})_4\right]^{2-}$ layers parallel to the (100) plane. These layers are interconnected through hydrogen bonds forming the structure of $\text{Na}_2\text{Ni}(\text{SO}_4)_2 \cdot 10\text{H}_2\text{O}$. The interatomic distances and the hydrogen bonds are listed in Tables 3 and 4, respectively.

The nickel cations are coordinated to six water molecules forming isolated distorted $\mathrm{[Ni(H_2O)_6]}^{2^+}$ octahedra. These octahedra are interlinked by the O6-H6a \cdots O9 hydrogen bonds forming the layer 2 parallel to the (100) plane (Fig. 8c). The $d_{\text{Ni1-}}$ $_{\text{O}}$) distances range from 2.0365 to 2.0892 Å with an average distance of 2.0555 A which is slightly shorter than the sum of the effective ionic radii of the six-coordinated Ni^{2+} and O^{2-} ${IR}_{(Ni^{2+})}$ + IR_(O²⁻) = 0.69 + 1.4 Å}.³⁸ The BVS value of 2.03 is in

good agreement with the oxidation state 2+ expected for the Ni atoms.³⁹

The $SO₄$ tetrahedra are regular. The distances range from 1.4607 to 1.4842 Å with the average value of 1.4740 Å. This value is shorter than the sum of the effective ionic radii of the fourcoordinated S⁶⁺ and O²⁻{IR_(S⁶⁺) + IR_(O²⁻) = 0.12 + 1.38 Å}. The BVS value of 6.00 is in good agreement with the oxidation state 6+ expected for sulfur.

The $Na1^+$ cations are surrounded by six oxygen atoms forming distorted octahedra. These octahedra share edges and form infinite chains running along the b axis (Fig. 8b). These chains share corners with the SO_4 tetrahedra forming $[Na_2(SO_4)_2(H_2O)_4]^2$ layers parallel to the (100) plane (see layer 1 in Fig. 8b). The average Na1–O distance of 2.4537 \AA is consistent with the sum of the effective ionic radii of the six-coordinated Na⁺ and O²⁻ {IR_(Na⁺) + IR_(O²⁻) = 1.02 + 1.40 Å}. The BVS value of 1.04 is in good agreement with the oxidation state 1+ expected for the Na atoms.

In Na₂Ni $(SO_4)_2$ 10H₂O the water molecules are the hydrogenbond donors, whereas the oxygen atoms O1, O3, O3, O4 and O9 play the role of hydrogen bond acceptors (Table 4 and Fig. 9).

^a Average distances are given in $\langle \rangle$ and coordination numbers are given in []. b Bond valence sum, B.V. = $e^{(r_0-r)/b}$ with the following parameters: $b = 0.37, r_0 \text{ (Na}^{\text{I}} - \text{O)} = 1.803, r_0 \text{ (S}^{\text{VI}} - \text{O)} = 1.624, r_0 \text{ (Ni}^{\text{II}} - \text{O)} = 1.654 \text{ and } r_0$ $(Mn^{II}-O) = 1.624.$

The hydrogen bonds can be divided into two categories; intraand inter-layers bonds as depicted on Fig. 9a, c and b, respectively. Based on the classification of Jeffrey all the O-H \cdots O hydrogen bonds are moderate (Table 4 and Fig. 9). $40,41$

It is worth to mention that in the nickel system $Na₂$ - $Ni(SO₄)₂·nH₂O$ four phases have been reported (*n* = 0, 2, 4 and 6), however only the crystal structures of $\text{Na}_2\text{Ni}(\text{SO}_4)_2$,²⁴ Na_2 - $Ni(SO₄)₂·4H₂O²⁵$ and $Na₂Ni(SO₄)₂·6H₂O²⁶$ were solved (Fig. 10). Theses phases were prepared via solid state-, room temperatureand hydrothermal-synthesis routes, respectively and using

Fig. 6 Perspective view along the a axis of the crystal structure of $Na₂Mn(SO₄)₂·4H₂O$ (a). The dashed blue lines correspond to the O-H \cdots O hydrogen bonds interconnecting the [Mn(SO₄)₂(H₂O)₄]²⁻ building blocks involving the water molecules H6a–O6–H6b (b) and H5a–O5–H5b (c). The sodium atoms are located in the tunnels (a).

different precursors and solvents. These experimental conditions are at the origin of the variation in the degree of hydration n of the Na₂Ni(SO₄)₂ nH_2O phases which induced several

Fig. 7 Synthesis methods and crystal structure views for Na₂Mn(SO₄)₂·4H₂O (a), Na₂Mn(SO₄)₂·2H₂O (b), Na_{2+v}Mn_{1-y/2}(SO₄)₃ (c), Na₁₂Mn₇(- SO_4 ₁₂[S₂O₇] \cdot 12H₂O (d) and Na₂Mn(SO₄)₂ (e). The coordination spheres of the Mn atoms are also provided for comparison.

structural changes. Our careful analyses indicate that the presence of water molecules affects in first place the coordination sphere of the transition metal (nickel) due to its large electrical charge z. Indeed, for $n = 0$, the NiO₆ octahedra share one edge and four corners with five $SO₄$ tetrahedra leading to $\left[\text{Ni}(\text{SO}_4)_2\right]^2$ ⁻ 3d-framework (Fig. 10d). Whereas, for $n=4$, the Ni atoms are coordinated to four water molecules and two oxygen atoms, from two adjacent SO₄ tetrahedra, forming the isolated $\left[\text{Ni(SO}_4)_2\text{(H}_2\text{O})_4\right]^{2-}$ building block of the blödite-type of structure (Fig. 10a). For $n = 6$ and 10, six water molecules are coordinated to the Ni atoms forming the isolated $\mathrm{[Ni(H_2O)_6]}^{2+}$ octahedra (Fig. 10b and c) which are connected to the SO_4 tetrahedra only through hydrogen bonds. For $n = 10$, the $(n - 6)$ extra water molecules are coordinated to the sodium atoms.

Since $n \leq 10$, in the four phases the water molecules are coordinated. One would expect to observe interstitial water only for n > 12 . Indeed in the case of Na₂Mg(SO₄)₂·16H₂O, six water molecules are coordinated to the magnesium atoms, six water molecules are coordinated to the sodium atoms and four water molecules are interstitial.¹⁴ Therefore the chemical formula can be written as $\{[Na_2(H_2O)_6][Mg(H_2O)_6][SO_4)_2]\}\cdot 4H_2O.$

3.4. Comparison of the crystal structures

The quantitative comparison of the isotypic crystal structures within the Na₂M(SO₄)₂·4H₂O series (M = Mg, V, Mn, Fe, Co, Ni, Zn, Cd) and between the two isotypic structures of Na₂- $M(SO₄)₂ \cdot 10H₂O (M = Mg, Ni)$, respectively was performed using

Fig. 8 View along the b axis of the crystal structure of Na₂Ni(SO₄)₂·10H₂O (a), view of [Na₂(SO₄)₂/H₂O)₄]^{2–} layer 1 on the (100) plane (b) and view of $[Ni(H_2O)_6]^{2+}$ layer 2 on the (100) plane (c).

Fig. 9 View of the hydrogen bonds within the layer 1 (a), between layer 1 and layer 2 (b), and within the layer 2 (c).

the program compstru.⁴³⁻⁴⁶ The comparisons did not include the hydrogen atoms since in the various structural refinements different constrains/restrains on the water molecules were applied. Origin shifts of $(0, \frac{1}{2}, \frac{1}{2})$ and $(0, \frac{1}{2}, 0)$ were applied to the crystal structures of $Na₂Mn(SO₄)₂·4H₂O$ and $Na₂Ni(SO₄)₂$ - $10H₂$ O, respectively. All the crystal structures in the Na₂- $M(SO_4)_2 \cdot 4H_2O$ series were compared to $Na_2Ni(SO_4)_2 \cdot 4H_2O$ which was chosen as a reference. The numerical details of the comparisons are given in Table 5. The crystal structures of $Na₂Ni(SO₄)₂·4H₂O$ and its Mg, Fe, Co, and Zn analogues show a very high similarity $(2 < 0.02)$ due to similar ionic radii of the five metal cations. Larger differences were observed with Mn and Cd ($\Delta = 0.044$ and 0.079, respectively) due to their greater ionic radii. It should be also noted that the cell volume increases almost linearly with the ionic radii of the metal cations (Fig. 11).

The crystal structure of $Na₂Ni(SO₄)₂·10H₂O$ was also compared to the Mg analogue using the compstru program. As indicated in Table 5, the two isotypic compounds are essentially coincident ($\Delta = 0.005$). The largest deviations of 0.0444 and 0.0430 were observed for the atom pairs O1 and O3 of the $MgO₆$ octahedron.

4. Conclusion

After the recent discovery of the new polymorphic modification of $Na₂Mn₃(SO₄)₄$ and the solid solution $Na₂Mn_{3-x}Mg_x(SO₄)₄⁴⁷$ two other sulfate phases were prepared for the first time by a wet

Fig. 10 Synthesis methods and crystal structure views for Na₂Ni(SO₄)₂ · 4H₂O (a), Na₂Ni(SO₄)₂ · 6H₂O (b), Na₂Ni(SO₄)₂ · 10H₂O (c) and Na₂Ni(SO₄)₂ (d). The coordination spheres of the Ni atoms are also provided for comparison.

Table 5 Numerical details from the comparisons of the crystal structure of Na₂Ni(SO₄)₂ \cdot 4H₂O with isotypic structures in the Na₂M(SO₄)₂ \cdot 4H₂O series (M = Mg, V, Mn, Fe, Co, Ni, Zn, Cd), and between Na₂Mg(SO₄)₂.10H₂O and Na₂Ni(SO₄)₂.10H₂O using the compstru program (|u| is the atomic displacement)

Fig. 11 Unit-cell volumes as a function of the ionic radius of the M cation in the blodite-type of compounds $Na₂M(SO₄)₂·4H₂O$ (M = Mg, V, Mn, Fe, Co, Ni, Zn, Cd).

chemistry route and their crystal structures were solved using single crystal XRD data. $Na₂Mn(SO₄)₂·4H₂O$ with the blödite-type structure is the missing link in the series of $\text{Na}_2\text{M}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$ sulfates ($M = Mg$, V, Mn, Fe, Co, Ni, Zn, Cd), whereas Na2- $Ni(SO₄)₂·10H₂O$ is the first compound isostructural with the aristotype $\text{Na}_2\text{Mg}(\text{SO}_4)_2 \cdot 10\text{H}_2\text{O}$. The powder XRD data revealed

that only the nickel phase was almost pure, whereas the manganese phase was a mixture of at least three phases. The TGA data provided the optimal conditions to fully dehydrate the nickel phase. When $\text{Na}_2\text{Ni}(\text{SO}_4)_2 \cdot 10\text{H}_2\text{O}$ is heated at temperatures between 300 and 600 °C, the anhydrous phase WC-Na₂Ni $(SO_4)_2$ could be obtained. Interestingly, it is isostructural with SS-Na2- $Ni(SO₄)₂$ which was prepared by solid state synthesis route and it is thermally more stable than $Na₂Fe(SO₄)₂$ which is a suitable cathode material for NIBs. Therefore, the dehydration of hydrous sulfates and phosphates should be considered as a promising step toward further realization of novel cathode materials for NIBs.
