Regio- and diastereoselective synthesis of spiropyrroloquinoxaline grafted indole heterocyclic hybrids and evaluation of their anti-*Mycobacterium tuberculosis* activity†

Natarajan Arumugam, ^a Abdulrahman I. Almansour, ^a Raju Suresh Kumar, ^a Abdul Jaleel Mohammad Ali Al-Aizari, ^a Shatha Ibrahim Alaqueel, ^b Sevgi Kansız, ^c Vagolu Siva Krishna, ^d Dharmarajan Sriram ^d and Necmi Dege ^e

An efficient and eco compatible approach for the regio- and stereoselective synthesis of structurally diverse novel hybrid heterocycles comprising spiropyrrolidine, indenoquinoxaline and indole structural units in excellent yields, has been achieved through a one-pot multicomponent process involving 1,3-dipolar cycloaddition as a key step. The 1,3-dipolar component is the azomethine ylide generated *in situ* from indenoquinoxaline and L-tryptophan and reacts with various substituted β -nitrostyrenes affording the spiroheterocyclic hybrids. The ring system thus created possesses two C–C and three C–N bonds and four adjacent stereogenic carbons, one of which is quaternary and the reaction proceeded with full diastereomeric control. All the synthesized compounds were assayed for their *in vitro* activity against *Mycobacterium tuberculosis* H37Rv using MABA assay. Interestingly, the compound bearing a 2-fluoro substituent on the aryl ring displayed an equipotent activity (MIC 1.56 μ g mL⁻¹) to ethambutol against *Mycobacterium tuberculosis* H37Rv.

1. Introduction

Tuberculosis (TB) is a chronic infectious disease caused by *Mycobacterium tuberculosis* bacteria (MTB), that has become an important world-wide public health problem.¹ According to the World Health Organization (WHO), approximately 10 million people are believed to be infected with TB annually with almost 1.5 million deaths.² Further, HIV-infected patients have an elevated risk of primary or reactivated tuberculosis, and such an active infectious process may enhance HIV replication and increase the risk of death.³ It is estimated that about one third of the world's population is infected with latent tuberculosis.

Currently available first line anti-TB medications *viz.*, ethambutol, isoniazid, pyrazinamide and rifampicin suffer from associated side-effects, poor efficacy in eradicating dormant pathogens and prolonged treatment.⁴ The second line anti-TB drugs such as bedaquiline, delamanid and pretomanid are generally more toxic, less effective and more expensive than the first line anti-TB drugs. Besides, the existence of multidrug and extensively drug resistant tuberculosis (MDR-TB and XDR-TB) further intensifies the problems connected with TB treatment. As patients could become virtually untreatable with the currently available anti-TB drugs, it is imperative to develop structurally diverse, novel, effective, fast acting and affordable anti-TB drugs having a unique mechanism of action with reduced toxicity profiles, capable of overcoming the resistances posed by MDR-TB and XDR-TB to efficiently combat this disease.

In this perspective, spiro compounds are very attractive structural motif for drug discovery since they are intrinsically three dimensional structures that can facilitate interactions with three dimensional binding sites more easily than planar aromatic ring system as ligand. A large number of spiro compounds found in natural products evolved to interact more efficiently with binding pockets in proteins and have better solubility, a crucial property in the process of drug development. Among them, pyrrolidines embedded in a spiro core are prevalent in several alkaloids and synthetic analogs including

Scheme 1 Synthetic strategy for spiropyrrolo-indenoquinoloxaline tethered indole analogs.

spirotryprostins A and B,⁵ horsfiline,⁶ elacomine,⁷ formosanine,⁸ rhynchophylline,⁹ MI-219, MI-773 and MI-888. These spiropyrrolidine heterocyclic hybrids displayed interesting biological properties including anticancer,^{10–12} antimycobacterial,¹³ anti-inflammatory, anti-microbial,¹⁴ analgesic,¹⁵ local anesthetic¹⁶ and AChE inhibition activities.^{17–19} Earlier studies showed that spiropyrrolidine heterocyclic hybrids displayed significant antimycobacterial activities that are comparable or superior to those of some of the currently employed first line TB drugs.²⁰

Despite their biological significances, the syntheses of spiropyrrolidine containing indole side chains have received little attention. In the context of our research in the field of 1,3-dipolar cycloadditions,^{21–29} herein we report an easy access to the target spiropyrrolo-indenoquinoloxaline-indole heterocyclic hybrids *via* a one-pot, green synthetic protocol employing a 1,3-dipolar cycloaddition in ionic liquids. The synthetic strategy planned for the preparation of spiropyrrolo-indenoquinoloxaline tethered indole heterocyclic hybrid has been described in Scheme 1. The 1,3-dipole derived from L-tryptophan is relatively less explored in the literature and, to best of our knowledge, this is the first report of the synthesis of 4-nitro-3-phenylspiro[indenol[1,2-*b*]quinoxaline-pyrrolidin-5-yl)methyl]-indole *via* one of such a novel class of azomethine ylide, derived from indenoquinolinone and L-tryptophan together with their biological evaluation.

2. Results and discussion

2.1 Chemistry

Our synthetic study begins with a pilot experiment that involved refluxing a mixture of *o*-phenylenediamine **1**, ninhydrin **2**, L-tryptophan **3** and β -nitrostyrene **4k**³⁰ in methanol for 2 h, which led to the isolation of 3-((4'-nitro-3'-phenylspiro[indenol[1,2-*b*]quinoxaline-11,2'-pyrrolidin]-5'-yl)methyl)-1*H*-indole **6k** as a single diastereoisomer in 75% yield. The same reaction was also examined in different solvents including ethanol, acetonitrile, 1,4-dioxane and methanol : 1,4-dioxane (1 : 1 v/v) under reflux. A slightly improved yield of the product **6k** (77%) was observed in MeOH : 1,4-dioxane mixture (Table 1, entry 4). Furthermore, the reaction optimization was also investigated in

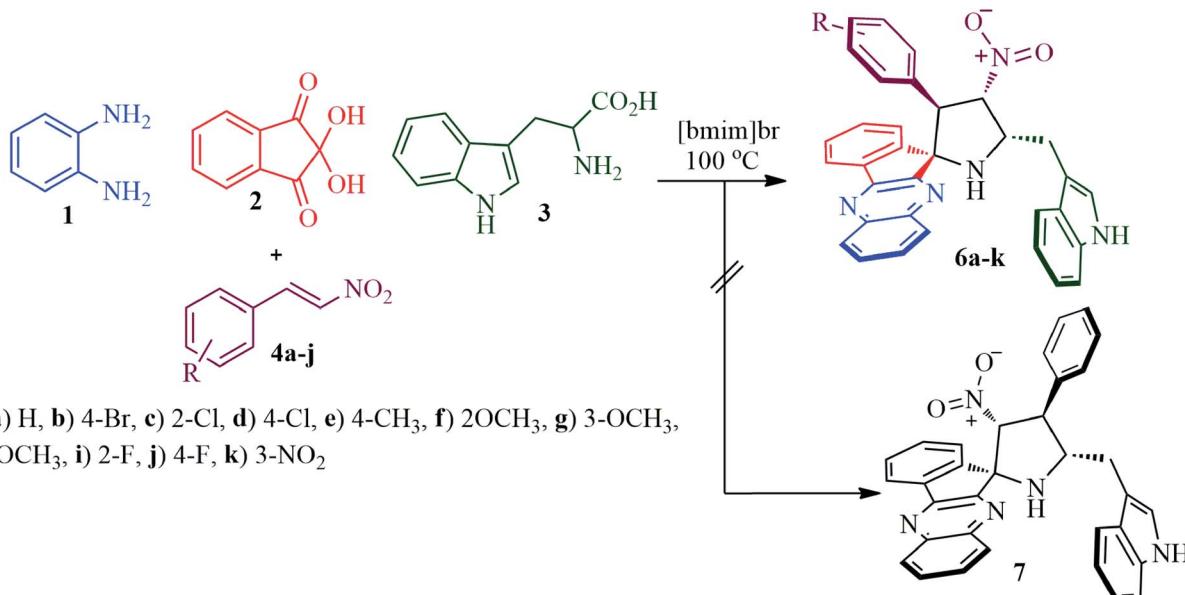

an ionic liquid [bmim]Br, which led to the formation of the desired product in an excellent yield of 86% (Table 1, entry 5) in a short reaction time (Scheme 2). Following the optimization study, all subsequent reactions were effected by heating an equimolar mixture of the reactants in [bmim]Br in an oil bath at 100 °C for 45 min and the products **6** were furnished in excellent yields, whilst the ionic liquid could be recovered and reused by simple drying under vacuum. The other possible regioisomer of **6**, *i.e.*, compound **7** was not observed even in traces (Scheme 1). It is pertinent to note that the reaction proceeded in a highly regio- and stereoselective fashion generating two new C–C, three C–N bonds and four adjacent stereocenters, one of which is a spiro carbon, in a single operation. It is noteworthy to mention that the rate of the reaction was accelerated by [bmim]Br³¹ as it possesses electron deficient hydrogen atom which could form hydrogen bonds with heteroatoms of the starting substrates thereby catalyzing the reactions. This multicomponent reaction progressed in a short reaction time with high yield as evidenced by our earlier reports.^{32–34}

Structural elucidation of the regioselective spiroheterocyclic hybrids was done carefully using 1D and 2D NMR spectroscopic analysis (*vide* supporting data) as discussed for a representative example, **6k** (Fig. S1,† *vide* supporting data). In the ¹H NMR spectrum, the H-3 hydrogen appear as a doublet at δ 5.04 ppm (J = 10.0 Hz) which showed H,H-COSY correlation with the triplet at δ 6.75 ppm (J = 9.0 Hz) being assignable to H-4 hydrogen which in turn shows HMBCs (Fig. 1) with the spirocarbons (C-2) and C-4 at δ 72.5 and δ 91.0 ppm respectively. The H-4 hydrogen also showed (i) H,H-COSY correlation with a multiplet at δ 5.13–

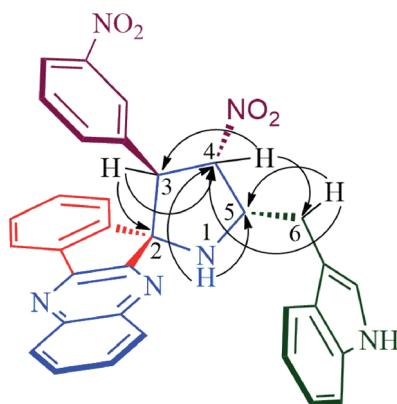

Fig. 1 Selected HMBCs of 6k.

5.19 ppm ascribable to H-5 hydrogen(ⁱⁱ) HMBCs with C-3 and C-6 at δ 57.3 and δ 28.6 ppm respectively. H-5 hydrogen showed H,H-COSY correlation with the doublet of doublets at δ 3.00–3.05 and δ 3.09–3.13 ppm due to H-6 hydrogens. H-6 showed HMBCs with C-5 and C-4 at δ 58.5 and δ 91.0 ppm respectively (*vide* supporting data). Finally, the regio- and stereochemistry of the spiro cycloadduct was unambiguously ascertained by single crystal X-ray diffraction analysis of 6e (Fig. 2).³⁵

The X-ray diffraction data of 6e was collected on STOE IPDS 2 (Stoe Imaging Plate Diffraction System II) diffractometer with graphite-monochromatized Mo-K α radiation ($\lambda = 0.71073 \text{ \AA}$).³⁶ The crystal structure was solved by SHELXT³⁷ and refined anisotropically by using SHELXL17/1 (ref. 38) software. WinGX³⁹ software was used to prepare material for publication. An additional solvent molecule (2-butanol) of partial occupancy was removed with the SQUEEZE procedure in PLATON.⁴⁰ The

asymmetric unit of 6e compound is shown in Fig. 2 and, crystal data, data collection and structure refinement details are summarized in Table S1† (*vide* supplementary data). Its asymmetric unit contains one independent molecule. The molecular structure is stabilized by the intramolecular C–H···N hydrogen bond (Fig. 2). The crystal packing of 6e features C–H···O and N–H···N hydrogen bonds (Fig. 3 and Table S2,† *vide* supplementary data). The N–O bond lengths [1.208 (2) and 1.198 (3) Å] in the nitro group are close to the values observed for related compounds reported in the literature.^{41–43} The detailed crystallographic and density functional theory (DFT) studies of spiropyrrolidine will be investigated in due course.

The reaction presumably proceeds through a mechanism proposed in Scheme 3. Thus, the mono ketone 5 initially formed by the reaction of *o*-phenylenediamine 1 and ninhydrin 2 reacts with L-tryptophan 4 to generate the 1,3-dipole 10 *via* imine 8 and isoxazolidinone intermediate 9. Subsequently, the 1,3-dipole component 10 attacks the β -carbon of styrene 4 regioselectively to afford the spirocycloadduct 6 (Scheme 2). Furthermore, the spiroheterocycle 6 was obtained with complete stereoselectivity. The aryl ring substituted to the pyrrolidine ring adjacent to the spiro carbon being *cis* to the quinoxaline unit and *trans* to the nitro group. The transition state (TS1) reveals the unfavorable interaction between the phenyl ring and quinoxaline unit of indenoquinoxaline moiety leading to the unobserved stereoisomer (Scheme 4).

2.2 Biology

Compounds 6a–k thus synthesized were evaluated for their *in vitro* antimycobacterial activity against *Mycobacterium tuberculosis* H37Rv by microplate alamar blue assay (MABA) and test results were presented as minimal inhibition concentration (MIC in $\mu\text{g mL}^{-1}$) as described in Table 2. The following three

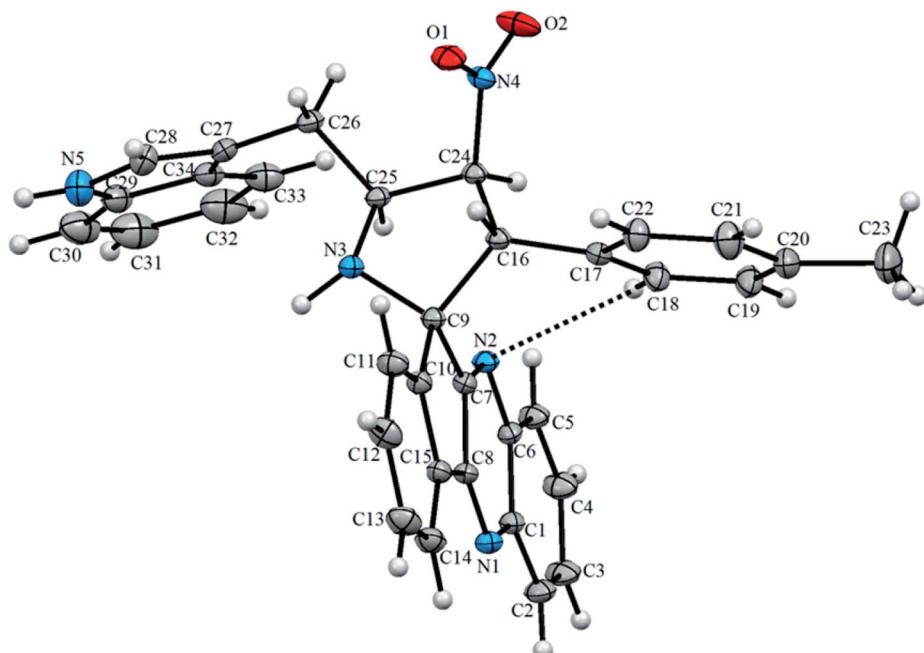

Fig. 2 The asymmetric unit of **6e**. Dashed line denotes the intramolecular C–H...N hydrogen bond.

anti-TB leads such as Isoniazid, rifampicin and ethambutol were used as reference standard. Among the synthesized spiropyrrolo-indenoquinoxaline tethered indole heterocyclic hybrids, the four compounds **6b**, **6c**, **6i** and **6j** showed moderate to potent activity which is comparable to that of the standard drug, Ethambutol. Compounds **6i** with *o*-fluoro and **6j** with *p*-

fluoro substituent on the aryl ring possesses remarkable activity against MTB with MIC values 1.56 and 3.125 $\mu\text{g mL}^{-1}$, respectively while compounds **6b** and **6c** bearing *p*-bromo and *o*-chloro substituent on the aryl ring displayed moderate activity against MTB with MIC values 6.25 and 12.5 $\mu\text{g mL}^{-1}$, respectively. Compound **6i** bearing 2-fluoro on the aryl ring exhibited

Scheme 4 Explanation of unobserved stereoselectivity.

equipotent activity as ethambutol (MIC = $1.56 \mu\text{g mL}^{-1}$). The three potent anti-TB compounds *viz.*, **6b**, **6i** and **6j** were tested for their toxicity on normal cell lines. As *Mycobacterium tuberculosis* resides in macrophages, we have tested them on Raw 264.7 macrophage

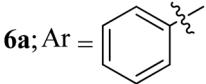

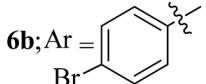

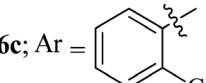

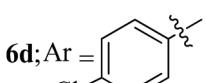

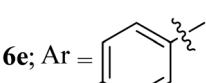

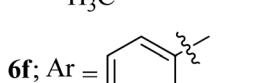

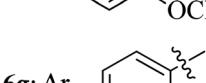

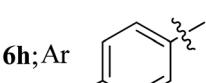

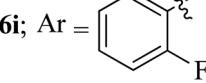

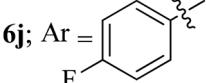

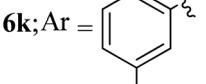

cell lines and these compounds were found to be safe at $50 \mu\text{g mL}^{-1}$ test concentration. The percentage of inhibition data of these compounds is summarized in Table 2. The above results revealed that spiropyrrolidines possessing halogen substituents on the phenyl ring displayed significant activity, in particular fluoro substituted spiroheterocyclic hybrids displayed excellent activity.

3. Conclusion

The present study describes a regio- and stereoselective synthesis of spiropyrrolo-indenoquinoxaline tethered indole heterocyclic hybrids in excellent yields *via* $[\text{bmim}] \text{Br}$ accelerated multicomponent cascade reaction protocol. It is pertinent to note that a new class of non-stabilized 1,3-dipole component generated from L-tryptophan and indenoquinolinone was employed. The spiroheterocyclic hybrids possess two C–C and three C–N bonds and four contiguous stereocenters, out of which one is a spirocarbon. *In vitro* antimycobacterial activity of

these synthesized compounds against *Mycobacterium tuberculosis* H37Rv revealed that the spiroheterocyclic hybrid bearing *o*-fluoro substituent on the phenyl ring (**6i**) displayed the most potent activity ($1.56 \mu\text{g mL}^{-1}$) and less toxicity on Raw 264.7

macrophage cell lines at $50 \mu\text{g mL}^{-1}$ concentration suggesting that this compound would be a promising hit for the development of new anti-TB lead compounds.

4. Material and methods

4.1 Synthesis of spiropyrrolo-indenoquinoxaline tethered indole heterocyclic hybrids, 6a–k

An equimolar mixture of aryl diamine **1**, triketone **2**, L-tryptophan **3** and β -nitrostyrene **4** in [bmim]Br (200 mg) were heated with stirring at 100 °C for 45 min. After completion of the reaction (TLC), ethyl acetate (10 mL) was added and the reaction mixture was further stirred for 10 min. The ethyl acetate layer was separated and the solvent was removed under reduced pressure to afford **6** in excellent yields.
