An approach to new chiral bicyclic imines and amines *via* Horner–Wadsworth–Emmons reaction†

Jakub Iwanejko,^a Mateusz Sowiński,^a Elżbieta Wojaczyńska,^{id} ^{*a}
Tomasz K. Olszewski^{id} ^{*a} and Marcin Górecki^b

New chiral bicyclic imines, enamines and amines were prepared *via* Horner–Wadsworth–Emmons reaction of hexahydroquinoxalin-2(1*H*)-one-derived phosphonate, as the source of a phosphonate carbanion, and a wide range of structurally diverse carbonyl substrates. The simplicity of the synthetic protocol, high selectivity, and broad substrate scope are the main advantages of the presented methodology.

Introduction

Chiral cyclic imines, particularly derivatives with five- and six-membered rings, have arisen as an important class of nitrogen containing heterocycles, useful as synthetic intermediates of drugs, agrochemicals and pharmacologically relevant compounds.¹ Among the latest examples, Zhang *et al.* described the preparation of an enantioenriched cyclic imine using Bosch's chiral lactam; the imine was applied for the construction of an important component in the total asymmetric syntheses of drugs, (–)-rhynchophylline and (+)-isrhynchophylline.² Wu *et al.* reported a rhodium-catalyzed asymmetric 1,2-addition of arylboronic acids to six-membered 1,2,6-thiadiazinane 1,1-dioxide-type cyclic imines to afford highly optically active sulfamides (95–99% ee).³ High diastereoselectivity and enantioselectivity was observed in a [4 + 2] reaction between cyclic sulfonic imine and Boc-protected indole aldehyde yielding polycyclic pyridoindoles.⁴ Aza-Darzens reaction of cyclic *N*-sulfonylimines with α -halogenated ketones provided a variety of tri- and tetrasubstituted aziridines, including benzofused heterocycles as well as spiro-structures in high yields, diastereo- and enantioselectivities (up to >20 : 1 dr and >99.9% ee).⁵ Among the known bicyclic heterocycles, the hexahydroquinoxaline-2(1*H*)-one derivatives represent an interesting new class of compounds with promising biological activity (Fig. 1),⁶ and can be considered as direct analogues of quinoxalin-2(1*H*)-ones, well known for their broad pharmacological properties *e.g.* inhibitors against Hepatitis C Virus (HCV) and potent candidates for antitumor therapeutics.⁷

Surprisingly in spite of interesting biological properties, preparation of hexahydroquinoxaline-2(1*H*)-one derivatives still remain problematic and there are only few synthetic strategies that allow access to those molecules (Scheme 1). Unfortunately, each of them suffers from some drawbacks and limitations. The classical approach is based on condensation of cyclohexane-1,2-diamine with pyruvates (the Hinsberg reaction) (Scheme 1a).^{8a,b} Unfortunately the chemical diversity using the latter methodology is limited by not always easy access to a wide range of pyruvates. Recently, a solid supported methodology was introduced by the group of Bräse using immobilized oxazolones in combination with difunctional nucleophiles and yielding heterocyclic products (Scheme 1b).^{8c} This method, however,

Scheme 1 Possible routes to hexahydroquinoxaline-2(1H)-one derivatives.

requires preparation in each case of new substituted oxazolone fragment and its subsequent introduction onto the resin which cannot be considered as straightforward process. Finally, palladium-catalyzed aminocarbonylation/cyclization synthetic strategy based on the use of carbon monoxide, cyclohexane-1,2-diamine and iodoindoles was introduced (Scheme 1c).^{8d} The need of using metal catalyst as well as narrow substrates scope are among the major limitations of this method.

In continuation of our interest in preparation of new heterocyclic compounds,⁹ we have recently reported on the synthesis of chiral hexahydroquinoxalin-2(1H)-one-derived phosphonates and identified them as intermediates for the asymmetric synthesis of hexahydroquinoxalin-2(1H)-one derivatives, especially bicyclic nitrogen-containing phosphonic acids but also imines and enamines.¹⁰ Importantly, the latter application, in contrast to the known approaches toward the preparation of those heterocycles, allows for an easy modification of the substituents around the carbon–nitrogen bond thus providing a selective and simple way to access those valuable building blocks. Herein, we present a detailed study on the scope and limitations of the application of

hexahydroquinoxalin-2(1H)-one-derived phosphonate, as the source of phosphonate carbanion, in the Horner–Wadsworth–Emmons reaction¹¹ leading selectively to chiral heterocyclic imines, and amines as well as the use of the obtained compounds as building blocks in the preparation of other interesting bicyclic derivatives.

Results and discussion

The core intermediate in our approach, chiral hexahydroquinoxalin-2(1H)-one derived dimethyl phosphonate **2**, can be easily accessed, even on a multigram scale, *via* a simple two-component phospho-Mannich reaction between chiral imine **1** and dimethyl *H*-phosphonate (Table 1).^{10a} Subsequent Horner–Wadsworth–Emmons (HWE) reaction performed in the presence of NaH in THF at 0 °C with a variety of aldehydes gave after total 2 h reaction time an access to structurally diverse products as tautomeric mixture of imine and enamine in which, in most cases, the imine form (**3**) predominated (Table 1). Composition of reaction mixtures in each case could be unambiguously established by ¹H NMR spectroscopy; measurements were

^a Pure imine isolated.

performed after an extraction step on the crude products (see ESI† for details of experimental procedures).

When simple aliphatic aldehydes, acetaldehyde and butyraldehyde (Table 1, entry 1 and 3) were used, imine : enamine ratio of *ca.* 3 : 2 was found. The use of reactants with longer aliphatic chains significantly improved the selectivity of the reaction, leading predominantly to stable imines with a chemical yield of up to 90% (Table 1, entries 5 and 6).

Application of branched aldehydes provided stable substituted imines with high selectivity and yield (entries 7–9). Importantly, the desired imines were also obtained in case of cyclic aldehydes (entries 10–12). It was observed that the selectivity of the HWE reaction increased with ring enlargement. The derivative with the cyclopropyl substituent proved to be unstable (Table 1 entry 10). While the use of benzaldehyde led mainly to enamine in 98% yield,^{10a} benzyl aldehyde afforded practically only imine product in 77% yield (Table 1, entry 13). Similarly, high chemoselectivity was observed for other aldehydes bearing phenyl substituent at the alkyl chain (entries 14 and 15). Since citronellal and 3-phenylbutyraldehyde were used as racemic mixtures (entries 6 and 15), the resulting products bear an additional asymmetric center.

Lower selectivity was noted for aldehydes containing heteroatoms in their structure (Table 1, entries 16–18). The presence of sulfonyl group resulted in the reversed selectivity (imine : enamine ratio of *ca.* 2 : 3); also enantiomerically pure bicyclic aldehyde-2-azabicycloalkane derivative resulted in unstable unsaturated products, predominantly enamine (Table 1, entry 18).

The crude mixtures were separated using column chromatography on silica gel. In general, we observed that the mixtures of tautomers containing above 90% of imine form were much

easier separable. Newly synthesized and isolated imines were found to be stable both in air atmosphere as well as in common organic solvents. On the other hand, mixtures containing at least 20% of enamine were inseparable neither by column chromatography nor crystallization, and were unstable. We observed slow decomposition of products (in solutions) into complex mixtures, and isolation of pure imine or enamine was not possible. However, immediate reduction of such reaction mixture obtained from HWE reaction could be performed yielding chiral amines (*vide infra*) (Table 2).

Additionally, HWE reaction was also performed with ketones. The use of acetophenone in the reaction with phosphonate 2 led to a complex mixture of olefination products that was reduced *in situ* and from the four possible diastereomeric products (two new stereogenic centers were formed) the pure main diastereomer was isolated in 32% overall yield (Scheme 2). The configuration of this product was determined on the basis of correlations found in 2D ¹H NMR spectra (see ESI† for details). To our delight, a nearly quantitative reaction was observed with acetone. Unfortunately, imine and enamine were formed in practically equimolar amounts (53 : 47 ratio) and we found them to be inseparable. Again, subsequent reduction of the crude reaction mixture was performed leading to mixture of chromatographically separable epimeric amines (71 : 29 diastereomeric ratio) from which both diastereomers was isolated in pure form with 63% and 25% overall yields (Scheme 2).

Subsequently, selected pure imines and also crude reaction mixtures containing imine and enamine were reduced with sodium borohydride (Table 2). An emphasis was put on the reduction of substrates bearing diverse substituents such as alkyl, cycloalkyl, alkylaryl groups as well as additional functional groups and heteroatoms. These reactions led to the

^a A tautomeric imine/enamine mixture was used. ^b In each case major diastereomer was isolated in pure form and absolute configuration was established (see ESI for details). ^c The value of dr established based on the ¹H NMR of crude reaction product. ^d Equimolar mixture of epimers.

formation of novel chiral amines with an additional stereogenic center. The resulting amines were purified by column chromatography and diastereomers were separated. Their configuration was established based on 2D NMR spectroscopy (Table 2). Reduction proceeded smoothly with a variable stereoselectivity which could be correlated with the steric hindrance exerted by the R substituent. This way, several enantiomerically pure amines **5a–e** bearing three or more stereogenic centers were isolated with moderate to good diastereoselectivity. It is noteworthy that there was no external source of chirality used – we have observed an induction of diastereoselectivity based on (R,R)-diaminocyclohexane fragment.

Finally, we decided to demonstrate the utility of the obtained hexahydroquinoxaline-2(1H)-one derivative imines as chiral building blocks in asymmetric preparation of other molecules. The imine **3i** was selected as model substrate (Scheme 3). Addition of phosphorus nucleophiles to imine **3i** provided corresponding aminophosphonic acid **6e** and aminophosphonate **6d** in high yield and excellent diastereoselectivity. In turn, reduction of the C=N bond in **3i** provided a mixture of epimeric amines **5a** (ca. 4 : 1 ratio) and the major epimer of **5a** could be separated by chromatography in 79% yield (Scheme 3). The latter was further subjected for reduction with lithium aluminum hydride to yield chiral cyclic diamine **6f** in 67% yield

(66% overall yield from **5a**, Scheme 3). In turn, to introduce sulfur functionality, cyclic imine **3i** and amine **5a** were treated with Lawesson's reagent (Scheme 3). Thioamide **6b** containing imine function was obtained with 63% yield from imine **3i** and also from amine **5a**, albeit in lower yield (34%). The reactivity of imine bond in this derivative was also checked. The aza-Pudovik reaction with dimethyl H-phosphonate appeared to proceed with a high diastereoselectivity comparable to **6d**, but with a low chemical efficiency (**6a**, 6% yield, not isolated). Finally, reduction of **6b** with sodium borohydride yielded amine **6c** bearing thiolactam fragment that was isolated in the form of two diastereomers that were isolated in pure form with 51% and 24% yield respectively (Scheme 3).

Determination of the absolute configuration of **6d** and **6e**

The assignment of absolute configuration (AC) of the main epimers **6d** and **6e** obtained in high diastereomeric excess was based on the comparison of their experimental and calculated electronic circular dichroism (ECD) spectra simulated using the time-dependent density functional theory (TDDFT). This combined methodology has illustrated its great efficiency in structural studies for many organic compounds having very different nature and origin.¹² The ECD spectra of **6d** and **6e** were measured in acetonitrile. They exhibit very similar profile which

Scheme 2 HWE reactions involving acetophenone and acetone.

is recognized by positive bands at *ca.* 240 and 200 nm, and negative one at *ca.* 220 nm (Fig. 2). This observation clearly indicates the same AC of newly formed chirality centre at C-4.

To rationalize the experimental observations and assign the AC at C-4, the TDDFT calculations were performed for (1*R*,4*R*,6*R*)-**6d** using CAM-B3LYP/def2-TZVP level of theory including a polarizable continuum solvent model (PCM) for CH₃CN. These simulations were preceded by a detailed

conformational search at the molecular mechanic level, and further re-optimization of the resultant structures at the DFT level by using the following combination: ω B97X-D/6-311+G(d,p)/PCM/CH₃CN. For computational details, see Experimental part and Table S1/ Fig. S1 and S2 in ESI† with structures of the most abundant conformers and their ECD spectra. As can be seen in Fig. 2, the calculated TDDFT spectrum perfectly stays in line with the experimental spectra. On

Scheme 3 The utility of imine **3i** as model substrate in further transformations.

Fig. 2 Experimental ECD spectra of the main epimers of **6d** and **6e** recorded in CH₃CN compared to simulated spectrum for (1*R*,4*R*,6*R*)-**6d** and (1*R*,4*S*,6*R*)-**6d** using CAM-B3LYP/def2-TZVP/PCM(CH₃CN) level of theory (UV shift = +17 nm, σ = 0.3 eV).

the strength of this, we can assign the AC of newly formed chirality centre for epimers obtained in high diastereomeric excess as 4*R*. At the same time, we confirmed that the AC at C-4 for the minor epimer is (4*S*). To improve this statement the same computational procedure was applied for simulating ECD spectrum of (1*R*,4*S*,6*R*)-**6d**. As a result, the obtained spectrum is contradictory to (1*R*,4*R*,6*R*)-**6d**, which further supports our assignment.

Conclusions

In summary, we have developed an efficient protocol based on the Horner–Wadsworth–Emmons reaction of easily available hexahydroquinoxalin-2(1*H*)-one-derived phosphonate and a wide range of carbonyl substrates leading to new diastereomerically pure bicyclic imines and amines. In most cases, reaction led selectively to the desired imines that were isolated in good to excellent yields. Subsequent reduction of the pure imines or tautomeric imine/enamine mixtures provided corresponding chiral amines in very good yields. We have also demonstrated that the obtained chiral heterocyclic compounds could be applied as useful synthetic intermediates in the synthesis of other useful derivatives in highly asymmetric manner and using simple transformations.

Experimental section

General information

Melting points were determined on the Schmelzpunkt Bestimmer Apotec melting-point apparatus using the standard open capillary method and are uncorrected. ¹H, ¹³C and ³¹P NMR spectra were collected on Jeol 400yh, Bruker Avance III 500 and Bruker Avance II 600 instruments. NMR spectra recorded in CDCl₃, D₂O and were referenced to the respective residual ¹H or ¹³C signals of the solvents. The reported *J* values are those observed from the splitting patterns in the spectrum and may not reflect the true coupling constant values. NOESY

experiments were carried out at 293 K. Infrared spectra (4000–400 cm^{−1}) were collected on a PerkinElmer 2000 FTIR spectrophotometer. High resolution mass spectra were collected using electrospray ionization on Waters LCT Premier XE TOF instrument. Optical rotations were measured using an Optical Activity Ltd. Model AA-5 automatic polarimeter; [α]^D values are given in 10^{−1} deg cm² g^{−1}. Chromatographic separations were performed on silica gel 60 (70–230 mesh). Thin layer chromatography was carried out using silica gel 60 precoated plates.

General procedure A for synthesis of cyclic imines 3a–s

Sodium hydride (60% dispersion in mineral oil, 1.30 mmol, 52.0 mg, 1.30 equiv.) was dispersed in anhydrous THF (10 mL) under argon atmosphere. The mixture was cooled to 273 K in an ice bath and then dimethyl-[(1*R*,6*R*)-3-oxo-2,5-diazabicyclo[4.4.0]dec-4-yl]phosphonate **2** (1.10 mmol, 288 mg, 1.10 equiv.) was added. The mixture was stirred for 30 minutes. The aldehyde was added (1.00 mmol, 1.00 equiv.) and the reaction continued for 30 minutes in 273 K and then for 60 minutes in a room temperature. Reaction mixture was washed with Et₂O (20 mL) and saturated NaHCO₃ solution (20 mL). The organic layer was dried (Na₂SO₄), filtered and evaporated under reduced pressure. Depending on yield and purity of crude product, the imines were described without additional purification or purified by silica gel column chromatography (eluent: CH₂Cl₂/MeOH 97 : 3 v/v).

General procedure B for synthesis of amines 4a–b

Sodium hydride (60% dispersion in mineral oil, 1.30 mmol, 52.0 mg, 1.30 equiv.) was dispersed in anhydrous THF (10 mL) under argon atmosphere. The mixture was cooled to 273 K in an ice bath and then dimethyl-[(1*R*,6*R*)-3-oxo-2,5-diazabicyclo[4.4.0]dec-4-yl]phosphonate **2** (1.10 mmol, 288 mg, 1.10 equiv.) was added. The mixture was stirred for 30 minutes. The ketone (acetophenone or acetone) was added (1.00 mmol, 1.00 equiv.) and the reaction continued for 30 minutes in 273 K and then for

60 minutes in a room temperature. Reaction mixture was washed with Et₂O (20 mL) and saturated NaHCO₃ solution (20 mL). The organic layer was dried (Na₂SO₄), filtered and evaporated under reduced pressure. The crude product was then dissolved in methanol (10 mL) at room temperature and sodium borohydride (1.30 mmol, 49.2 mg, 1.30 equiv. was added). The mixture was stirred for 3 hours. Solvent was evaporated under reduced pressure and the residue was subjected to column chromatography (eluent : CH₂Cl₂/MeOH 95 : 5 v/v) to obtain pure amines.

General procedure C for synthesis of amines 5a–e and 6c

To a solution of an appropriate imine (1.00 mmol, 1.00 equiv.) in methanol (10 mL) at room temperature was added sodium borohydride (1.30 mmol, 49.2 mg, 1.30 equiv.). The mixture was stirred for 3 hours. Solvent was evaporated under reduced pressure and the residue was subjected to column chromatography (eluent : CH₂Cl₂/MeOH 95 : 5 v/v) to obtain pure diastereomers of amine.

Procedure D for the synthesis of 6b

To a solution of imine **3i** (2.00 mmol, 444 mg, 2.00 equiv.) in toluene (15 mL), Lawesson's reagent (1.20 mmol, 485 mg, 0.600 equiv.) was added under an argon atmosphere. The reaction mixture was refluxed for 4 hours. Upon completion of the reaction (monitored by TLC), it was quenched with water (20 mL) and extracted with ethyl acetate (3 × 20 mL). The organic layer was dried over Na₂SO₄, filtered, and concentrated under reduced pressure. The crude product was purified by column chromatography (eluent : CH₂Cl₂/MeOH 98 : 2 v/v).

Procedure E for the synthesis of dialkyl aminophosphonic acid ester **6d** and aminophosphonic acid **6e**

Procedure E for the synthesis of dialkyl aminophosphonic acid ester **6d** and aminophosphonic acid **6e** can be found in the literature.^{10b}

Procedure F for reduction of 5a to bisamine **6f**

To a solution of **5a** (0.500 mmol, 112 mg, 1.0 equiv.) in anhydrous THF (5 mL) under argon atmosphere was added lithium aluminium hydride (0.750 mmol, 28.5 mg, 1.5 equiv.). The mixture was heated under reflux for 20 hours and then cooled down to room temperature. The reaction was quenched with addition of water (30 µL), NaOH (15% solution, 30 µL) and water (90 µL). Resulting suspension was filtered through Celite and washed with THF. The organic layer was dried (K₂CO₃), filtered and evaporated under reduced pressure and the resulting crude product was purified by column chromatography (eluent : CH₂Cl₂/MeOH 80 : 20 v/v).

4-Octyl-(1R,6R)-3-oxo-2,5-diazabicyclo[4.4.0]dec-4-ene (3e). Using general procedure A; colorless oil; 238 mg; yield = 90%; [α]_D²⁰ –109 (c 1.05, CH₂Cl₂); IR (KBr): 724, 1119, 1220, 1318, 1364, 1455, 1628, 1683, 2857, 2927, 3085, 3205 cm^{–1}; ¹H NMR (400 MHz, CDCl₃): δ 6.24 (br. s, 1H), 2.98–3.11 (m, 2H), 2.59–2.67 (m, 1H), 2.42–2.50 (m, 1H), 2.29–2.31 (m, 1H), 1.75–1.89

4-Cyclopentylmethyl-(1R,6R)-3-oxo-2,5-diazabicyclo[4.4.0]dec-4-ene (3k). Using general procedure A; off-white solid; 185 mg; yield = 79%; mp 121–123 °C; [α]_D²⁰ –105 (c 0.66, CH₂Cl₂); IR (KBr): 802, 1052, 1358, 1628, 1686, 2858, 2932, 3068, 3189 cm^{–1}; ¹H NMR (400 MHz, CDCl₃): δ 6.24 (br. s, 1H), 2.99–3.09 (m, 2H), 2.79 (ddd, *J* = 13.5, 6.7, 2.1 Hz, 1H), 2.29–2.39 (m, 2H), 2.17 (sept, *J* = 7.3 Hz, 1H), 1.14–1.89 (m, 15H); ¹³C NMR (100 MHz, CDCl₃): δ 165.7, 158.8, 62.5, 54.5, 39.6, 37.8, 32.6, 32.1, 31.9, 31.1, 25.2, 25.1, 25.0, 23.8; HRMS (ESI-TOF) calcd for C₁₄H₂₂N₂O [*M* + *H*]⁺ *m/z*: 235.1810, found: 235.1813.

4-Cyclohexylmethyl-(1R,6R)-3-oxo-2,5-diazabicyclo[4.4.0]dec-4-ene (3l). Using general procedure A; colorless solid; 169 mg; yield = 68%; mp 124–125 °C; [α]_D²⁰ –104 (c 0.98, CH₂Cl₂); IR (KBr): 810, 1222, 1364, 1444, 1618, 1677, 2851, 2931, 3065, 3095, 3184 cm^{–1}; ¹H NMR (400 MHz, CDCl₃): δ 6.31 (br. s, 1H), 3.02–3.10 (m, 2H), 2.69 (ddd, *J* = 13.3, 6.3, 1.8 Hz, 1H), 2.28–2.36 (m, 1H), 2.22 (dd, *J* = 13.1, 7.6 Hz, 1H), 1.59–1.89 (m, 8H), 1.09–1.41 (m, 8H), 0.88–1.02 (m, 2H); ¹³C NMR (100 MHz, CDCl₃): δ 165.6, 158.8, 62.5, 54.5, 41.1, 36.2, 33.5, 33.0, 31.9, 31.1, 26.4, 26.3, 26.2, 25.2, 23.7; HRMS (ESI-TOF) calcd for C₁₅H₂₄N₂O [*M* + *H*]⁺ *m/z*: 249.1967, found: 249.1960.

4-Phenethyl-(1R,6R)-3-oxo-2,5-diazabicyclo[4.4.0]dec-4-ene (3m). Known compound; using general procedure A; pale yellow solid; 179 mg; yield = 70%; mp 127–128 °C; [α]_D²⁰ –110 (c 0.55, CH₂Cl₂); IR (KBr): 499, 711, 756, 1358, 1624, 1678, 2863, 2934, 3064, 3188 cm^{–1}; ¹H NMR (400 MHz, CDCl₃): δ 7.14–7.28 (m, 5H), 6.52 (br. s, 1H), 2.82–3.03 (m, 6H), 2.29–2.32 (m, 1H), 1.76–1.90 (m, 3H), 1.25–1.41 (m, 4H); ¹³C NMR (100 MHz, CDCl₃): δ 164.9, 158.6, 141.5, 128.7 (2C overlapped), 128.4 (2C overlapped), 126.0, 62.6, 54.4, 35.4, 32.7, 31.2, 31.1, 25.3, 23.8; HRMS (ESI-TOF) calcd for C₁₆H₂₁N₂O [*M* + *H*]⁺ *m/z*: 257.1654, found: 257.1647.

4-Phenylpropyl-(1R,6R)-3-oxo-2,5-diazabicyclo[4.4.0]dec-4-ene (3n). Using general procedure A; off-white solid; 265 mg; yield = 98%; mp 115–117 °C; $[\alpha]_D^{20}$ –93 (c 0.40, CH₂Cl₂); IR (KBr): 701, 756, 1360, 1451, 1494, 1627, 1684, 2855, 2926, 3023, 3081, 3171 cm⁻¹; ¹H NMR (400 MHz, CDCl₃): δ 7.13–7.27 (m, 5H), 6.20 (br. s, 1H), 2.97–3.04 (m, 2H), 2.68 (q, *J* = 6.7 Hz, 1H), 2.66 (t, *J* = 7.6 Hz, 2H), 2.57 (q, *J* = 7.6 Hz, 1H), 2.29–2.31 (m, 1H), 1.69–1.94 (m, 5H), 1.24–1.41 (m, 4H); ¹³C NMR (100 MHz, CDCl₃): δ 165.5, 158.6, 142.2, 128.6 (2C overlapped), 128.4 (2C overlapped), 125.8, 62.5, 54.4, 35.7, 33.5, 31.9, 31.2, 28.5, 25.3, 23.8; HRMS (ESI-TOF) calcd for C₁₇H₂₂N₂O [M + H]⁺ *m/z*: 271.1810, found: 271.1806.

4-(3-Phenylbutyl)-(1R,6R)-3-oxo-2,5-diazabicyclo[4.4.0]dec-4-ene (3o). Using general procedure A; off-white solid; 196 mg; yield = 69%; mixture of epimers 1 : 1; mp 93–95 °C; IR (KBr): 696, 760, 1369, 1452, 1493, 1628, 1684, 2858, 2927, 3027, 3062, 3195 cm⁻¹; ¹H NMR (400 MHz, CDCl₃): δ 7.13–7.28 (m, 5H), 5.96 (br. s, 1H), 2.91–3.00 (m, 2H), 2.74 (sext, *J* = 7.6 Hz, 1H), 2.50 (q, *J* = 6.1 Hz, 1H), 2.27–2.30 (m, 1H), 1.62–1.94 (m, 5H), 1.21–1.41 (m, 5H), 1.27 (dd, *J* = 7.0, 2.3 Hz, 3H); ¹³C NMR (100 MHz, CDCl₃): δ 165.7, 158.5, 147.1, 128.4 (2C overlapped), 127.2 (2C overlapped), 126.0, 62.5, 54.3, 40.0, 34.9, 32.1, 31.9, 31.1, 25.3, 23.8, 22.3; HRMS (ESI-TOF) calcd for C₁₈H₂₄N₂O [M + H]⁺ *m/z*: 285.1967, found: 285.1963.

Full characteristic of compounds **3b**, **3d** and **3g** can be found in our previous paper.^{10a}

4-((S)-1-Phenylethyl)-(1R,4S,6R)-3-oxo-2,5-diazabicyclo[4.4.0]decane (4a). Using general procedure B; colorless oil; 83 mg; yield = 32%; $[\alpha]_D^{20}$ –16 (c 0.25, CH₂Cl₂); IR (KBr): 706, 772, 1121, 1343, 1357, 1452, 1664, 2855, 2929, 3178, 3447 cm⁻¹; ¹H NMR (400 MHz, CDCl₃): δ 7.31–7.34 (m, 2H), 7.23–7.28 (m, 2H), 7.18–7.21 (m, 1H), 5.95 (br. s, 1H), 3.78 (dq, *J* = 7.3, 3.4 Hz, 1H), 3.72 (d, *J* = 3.1 Hz, 1H), 2.37–2.41 (m, 2H), 1.60–1.85 (m, 4H), 1.45 (d, *J* = 7.3 Hz, 3H), 0.99–1.34 (m, 5H); ¹³C NMR (100 MHz, CDCl₃): δ 171.7, 141.7, 128.7 (2C overlapped), 128.2 (2C overlapped), 126.7, 64.4, 57.9, 57.7, 40.2, 31.6, 30.9, 24.9, 23.7, 18.1; HRMS (ESI-TOF) calcd for C₁₆H₂₃N₂O [M + H]⁺ *m/z*: 259.1810, found: 259.1812.

4-Isopropyl-(1R,4R,6R)-3-oxo-2,5-diazabicyclo[4.4.0]decane (4b). Using general procedure B; colorless solid; 123 mg; yield = 63%; mp 126–127 °C; $[\alpha]_D^{20}$ +27 (c 0.30, CH₂Cl₂); IR (KBr): 1157, 1364, 1464, 1643, 2862, 2935, 3188, 3327, 3449 cm⁻¹; ¹H NMR (400 MHz, CDCl₃): δ 6.89 (br. s, 1H), 3.41 (s, 1H), 2.92–2.98 (m, 1H), 2.42–2.48 (m, 1H), 1.73–1.93 (m, 5H), 1.15–1.46 (m, 4H), 1.30 (s, 3H), 1.25 (s, 3H), 1.02–1.15 (m, 1H); ¹³C NMR (100 MHz, CDCl₃): δ 173.1, 73.5, 63.5, 59.0, 55.8, 31.2, 30.8, 27.4, 26.6, 25.0, 23.7; HRMS (ESI-TOF) calcd for C₁₁H₂₁N₂O [M + H]⁺ *m/z*: 197.1654, found: 197.1649.

4-Isopropyl-(1R,4S,6R)-3-oxo-2,5-diazabicyclo[4.4.0]decane (4b'). Using general procedure B; colorless solid; 49 mg; yield = 25%; mp 120–122 °C; $[\alpha]_D^{20}$ +33 (c 0.30, CH₂Cl₂); IR (KBr): 827, 1352, 1364, 1465, 1658, 2860, 2931, 3195, 3321, 3418 cm⁻¹; ¹H NMR (400 MHz, CDCl₃): δ 6.04 (br. s, 1H), 3.32 (d, *J* = 4.6 Hz, 1H), 2.94–3.00 (m, 1H), 2.48–2.54 (m, 1H), 2.39 (dsep, *J* = 7.0, 4.9 Hz, 1H), 1.69–1.88 (m, 5H), 1.08–1.38 (m, 4H), 1.03 (d, *J* = 7.0 Hz, 3H), 0.93 (d, *J* = 7.0 Hz, 3H); ¹³C NMR (100 MHz, CDCl₃): δ 172.6, 77.3, 62.5, 58.9, 55.9, 31.6, 31.0, 24.9, 23.8, 20.3, 18.6; HRMS (ESI-TOF) calcd for C₁₁H₂₁N₂O [M + H]⁺ *m/z*: 197.1654, found: 197.1649.

4-Neopentyl-(1R,4S,6R)-3-oxo-2,5-diazabicyclo[4.4.0]decane (5a). Using general procedure C; colorless solid; 177 mg; yield = 79%; mp 182–184 °C; $[\alpha]_D^{20}$ –31 (c 0.16, CH₂Cl₂); IR (KBr): 1144, 1359, 1409, 1476, 1658, 2862, 2938, 3065, 3189, 3282 cm⁻¹; ¹H NMR (400 MHz, CDCl₃): δ 5.78 (br. s, 1H), 3.50 (dd, *J* = 8.4, 1.8 Hz, 1H), 2.97–3.03 (m, 1H), 2.45–2.51 (m, 1H), 2.23 (dd, *J* = 14.5, 2.5 Hz, 1H), 1.68–1.81 (m, 4H), 1.22–1.41 (m, 6H), 0.97 (s, 9H); ¹³C NMR (100 MHz, CDCl₃): δ 173.1, 58.7, 58.5, 58.3, 46.0, 31.7, 31.0, 30.6, 30.1 (3C overlapped), 24.8, 23.9; HRMS (ESI-TOF) calcd for C₁₃H₂₅N₂O [M + H]⁺ *m/z*: 225.1967, found: 225.1964.

4-Neopentyl-(1R,4R,6R)-3-oxo-2,5-diazabicyclo[4.4.0]decane (5a'). Using general procedure C; colorless solid; 43 mg; yield = 19%; mp 178–179 °C; $[\alpha]_D^{20}$ +32 (c 0.14, CH₂Cl₂); IR (KBr): 1120, 1362, 1408, 1467, 1659, 2860, 2936, 3058, 3180, 3300 cm⁻¹; ¹H NMR (400 MHz, CDCl₃): δ 5.70 (br. s, 1H), 3.60 (dd, *J* = 9.2, 4.5 Hz, 1H), 2.93–2.99 (m, 1H), 2.51–2.57 (m, 1H), 1.70–1.81 (m, 5H), 1.60 (dd, *J* = 14.4, 9.2 Hz, 1H), 1.54 (br. s, 1H), 1.12–1.40 (m, 4H), 0.99 (s, 9H); ¹³C NMR (100 MHz, CDCl₃): δ 174.1, 59.0, 56.4, 53.1, 46.3, 31.8, 31.1, 31.0, 29.9 (3C overlapped), 25.0, 23.9; HRMS (ESI-TOF) calcd for C₁₃H₂₅N₂O [M + H]⁺ *m/z*: 225.1967, found: 225.1964.

4-(Cyclohexylmethyl)-(1R,4S,6R)-3-oxo-2,5-diazabicyclo[4.4.0]decane (5b). Using general procedure C; colorless solid; 130 mg; yield = 52%; mp 155–156 °C; $[\alpha]_D^{20}$ +55 (c 0.29, CH₂Cl₂); IR (KBr): 1131, 1146, 1313, 1353, 1412, 1449, 1661, 2852, 2922, 3063, 3187, 3272 cm⁻¹; ¹H NMR (400 MHz, CDCl₃): δ 6.08 (br. s, 1H), 3.56 (dd, *J* = 9.6, 3.4 Hz, 1H), 2.98–3.03 (m, 1H), 2.45–2.51 (m, 1H), 1.93 (ddd, *J* = 13.8, 10.0, 3.4 Hz, 1H), 1.64–1.86 (m, 10H), 1.11–1.52 (m, 9H), 0.85–1.03 (m, 2H); ¹³C NMR (100 MHz, CDCl₃): δ 173.0, 58.5, 58.2, 56.9, 39.9, 34.4, 33.8, 31.9, 31.6, 30.8, 26.6, 26.4, 26.2, 24.8, 23.8; HRMS (ESI-TOF) calcd for C₁₅H₂₇N₂O [M + H]⁺ *m/z*: 251.2123, found: 251.2118.

4-(Cyclohexylmethyl)-(1R,4R,6R)-3-oxo-2,5-diazabicyclo[4.4.0]decane (5b'). Using general procedure C; colorless solid; 83 mg; yield = 33%; mp 174–175 °C; $[\alpha]_D^{20}$ +46 (c 0.34, CH₂Cl₂); IR (KBr): 1114, 1148, 1359, 1413, 1448, 1659, 2851, 2928, 3058, 3178, 3298 cm⁻¹; ¹H NMR (400 MHz, CDCl₃): δ 6.18 (br. s, 1H), 3.56 (dd, *J* = 7.2, 7.0 Hz, 1H), 2.93–2.99 (m, 1H), 2.48–2.54 (m, 1H), 1.60–1.81 (m, 12H), 1.08–1.30 (m, 8H), 0.84–1.04 (m, 2H); ¹³C NMR (100 MHz, CDCl₃): δ 174.0, 58.9, 55.6, 52.9, 39.9, 34.3, 34.2, 31.9, 31.6, 31.0, 26.6, 26.4, 26.1, 25.0, 23.9; HRMS (ESI-TOF) calcd for C₁₅H₂₇N₂O [M + H]⁺ *m/z*: 251.2123, found: 251.2118.

4-(3-Phenylpropyl)-(1R,4R,6R)-3-oxo-2,5-diazabicyclo[4.4.0]decane (5c). Using general procedure C; colorless solid; 114 mg; yield = 42%; mp 134–135 °C; $[\alpha]_D^{20}$ +36 (c 0.70, CH₂Cl₂); IR (KBr): 696, 752, 1364, 1417, 1452, 1496, 1655, 2857, 2931, 3059, 3174, 3296 cm⁻¹; ¹H NMR (400 MHz, CDCl₃): δ 7.24–7.28 (m, 2H), 7.14–7.19 (m, 3H), 6.29 (br. s, 1H), 3.47 (dd, *J* = 9.2, 4.0 Hz, 1H), 2.93–2.99 (m, 1H), 2.57–2.71 (m, 2H), 2.43–2.49 (m, 1H), 2.30 (br. s, 1H), 1.70–1.95 (m, 8H), 1.11–1.39 (m, 4H); ¹³C NMR (100 MHz, CDCl₃): δ 173.3, 142.3, 128.5 (2C overlapped), 128.4 (2C overlapped), 125.8, 58.9, 58.1, 53.3, 35.8, 32.6, 31.6, 30.9, 28.7, 25.0, 23.8; HRMS (ESI-TOF) calcd for C₁₇H₂₄N₂O [M + H]⁺ *m/z*: 273.1967, found: 273.1971.

4-(3-Phenylpropyl)-(1R,4S,6R)-3-oxo-2,5-diazabicyclo[4.4.0]decane (5c'). Using general procedure C; colorless solid; 95 mg;

yield = 35%; mp 58–60 °C; $[\alpha]_D^{20}$ –15 (c 0.48, CH₂Cl₂); IR (KBr): 696, 1352, 1409, 1453, 1496, 1659, 2854, 2934, 3026, 3061, 3190, 3269 cm^{–1}; ¹H NMR (400 MHz, CDCl₃): δ 7.25 (t, *J* = 7.0 Hz, 2H), 7.13–7.17 (m, 3H), 6.25 (br. s, 1H), 3.52–3.55 (m, 1H), 2.93–3.00 (m, 1H), 2.63 (t, *J* = 7.3 Hz, 2H), 2.43–2.49 (m, 1H), 2.00–2.05 (m, 1H), 1.69–1.81 (m, 8H), 1.21–1.36 (m, 4H); ¹³C NMR (100 MHz, CDCl₃): δ 172.3, 142.4, 128.5 (2C overlapped), 128.4 (2C overlapped), 125.8, 59.5, 58.4, 58.2, 36.1, 32.4, 31.5, 30.8, 28.1, 24.8, 23.9; HRMS (ESI-TOF) calcd for C₁₇H₂₄N₂O [M + H]⁺ *m/z*: 273.1967, found: 273.1971.

4-(3,7-Dimethyloct-6-en-1-yl)-(1*R*,4*S*,6*R*)-3-oxo-2,5-diazabicyclo[4.4.0]decane (5d). Using general procedure C; colorless solid; 120 mg; yield = 41%; mixture of epimers 1 : 1; IR (KBr): 812, 844, 1126, 1352, 1363, 1451, 1659, 2858, 2936, 3177, 3299, 3426 cm^{–1}; ¹H NMR (400 MHz, CDCl₃, both isomers present): δ 6.03 (br. s, 2H), 5.05–5.10 (m, 2H), 3.42 (ddd, *J* = 10.0, 3.7, 2.8 Hz, 2H), 2.96–3.02 (m, 2H), 2.49–2.56 (m, 2H), 1.41–2.03 (m, 18H), 1.66 (s, 6H), 1.58 (s, 6H), 1.09–1.54 (m, 18H), 0.88 (d, *J* = 6.4 Hz, 3H), 0.878 (d, *J* = 6.4 Hz, 3H); ¹³C NMR (100 MHz, CDCl₃, both isomers present): δ 173.3, 173.27, 131.2 (2C overlapped), 125.0, 124.9, 58.8, 58.77, 58.6 (2C overlapped), 53.3, 53.27, 37.2, 36.9, 34.2, 33.9, 32.6, 32.3, 31.6 (2C overlapped), 30.9 (2C overlapped), 30.5, 30.1, 25.8 (2C overlapped), 25.7, 25.5, 24.9 (2C overlapped), 23.8 (2C overlapped), 19.7, 19.5, 17.7 (2C overlapped); HRMS (ESI-TOF) calcd for C₁₈H₃₃N₂O [M + H]⁺ *m/z*: 293.2593, found: 293.2603.

4-(3,7-Dimethyloct-6-en-1-yl)-(1*R*,4*S*,6*R*)-3-oxo-2,5-diazabicyclo[4.4.0]decane (5d'). Dimethyl[4-neopentyl-(1*R*,4*R*,6*R*)-3-oxo-2,5-diazabicyclo[4.4.0]dec-4-yl]-phosphonate (6d). Using procedure E; colorless solid; 308 mg; yield = 87%; mp 103–105 °C; $[\alpha]_D^{20}$ +37 (c 0.35, CH₂Cl₂); IR (KBr): 1028, 1059, 1243, 1342, 1463, 1670, 2860, 2952, 3225, 3436 cm^{–1}; ¹H NMR (400 MHz, CDCl₃): δ 5.95 (br. s, 1H), 3.79 (d, *J* = 10.4 Hz, 6H), 3.05–3.07 (m, 2H), 2.36 (dd, *J* = 14.4, 3.1 Hz, 1H), 1.70–1.79 (m, 5H), 1.59 (dd, *J* = 14.4, 12.2 Hz, 1H), 1.15–1.41 (m, 4H), 1.00 (s, 9H); ¹³C NMR (100 MHz, CDCl₃): δ 169.4, 66.9 (d, *J* = 120.7 Hz), 57.5, 55.0, 54.0, 53.9, 53.8, 44.9, 32.2 (d, *J* = 15.0 Hz), 31.2 (3C overlapped), 30.7 (d, *J* = 13.2 Hz), 24.2, 23.9; ³¹P{¹H} NMR (162 MHz, CDCl₃): δ 27.2; HRMS (ESI-TOF) calcd for C₁₅H₂₉N₂O₄-PNa [M + Na]⁺ *m/z*: 355.1763, found: 355.1771.

[4-Neopentyl-(1*R*,4*R*,6*R*)-3-oxo-2,5-diazabicyclo[4.4.0]dec-4-yl]-phosphonic acid (6e). Using procedure E; colorless solid; 217 mg; yield = 72%; dr = 93 : 7; IR (KBr): 557, 1081, 1207, 1261, 1345, 1470, 1601, 1651, 2949, 3051, 3180 cm^{–1}; ¹H NMR (400 MHz, CDCl₃): δ 3.77–3.82 (m, 1H), 3.54–3.57 (m, 1H), 3.20 (s, 2H), 2.56 (dd, *J* = 15.9, 4.6 Hz, 1H), 1.51–2.05 (m, 5H), 1.16–1.30 (m, 2H), 0.92 (s, 9H); ¹³C NMR (100 MHz, CDCl₃): δ 167.9, 67.8 (d, *J* = 120.0 Hz), 57.0, 53.1, 48.9, 43.5, 30.3 (3C overlapped), 30.2, 26.8, 23.6, 22.4; ³¹P{¹H} NMR (162 MHz, CDCl₃): δ 9.9; HRMS (ESI-TOF) calcd for C₁₃H₂₆N₂O₄P [M + H]⁺ *m/z*: 303.1474, found: 303.1476.

4-Neopentyl-(1*R*,4*S*,6*R*)-2,5-diazabicyclo[4.4.0]decane (6f). Using procedure F; colorless solid; 70 mg; yield = 67%; mp 42–44 °C; $[\alpha]_D^{20}$ +24 (c 0.17, CH₂Cl₂); IR (KBr): 833, 1113, 1325, 1366,

1450, 1466, 1650, 2854, 2927, 3273, 3413 cm^{-1} ; ^1H NMR (400 MHz, CDCl_3): δ 2.92 (dd, $J = 11.6, 3.1$ Hz, 1H), 2.77–2.82 (m, 1H), 2.49 (dd, $J = 11.6, 10.4$ Hz, 1H), 2.25–2.31 (m, 1H), 2.16–2.21 (m, 1H), 1.58–1.71 (m, 4H), 1.56 (br. s, 2H), 1.14–1.33 (m, 6H), 0.91 (s, 9H); ^{13}C NMR (100 MHz, CDCl_3): δ 61.9, 60.5, 54.27, 54.25, 48.8, 32.3, 32.0, 30.5, 30.1 (3C overlapped), 25.1, 24.9; HRMS (ESI-TOF) calcd for $\text{C}_{13}\text{H}_{27}\text{N}_2$ $[\text{M} + \text{H}]^+$ m/z : 211.2174, found: 211.2169.

ECD measurement

ECD spectra were carried out using a Jasco J-815 spectrometer (Tokyo, Japan) at room temperature in spectroscopic grade CH_3CN (6.0×10^{-4} M) in quartz cells with a path length 0.1, 0.2 or 1 cm. All spectra were measured using a scanning speed of 100 nm min^{-1} , a step size of 0.2 nm, a bandwidth of 1 nm, a response time of 0.5 seconds, and an accumulation of 5 scans. The spectra were background-corrected using solvent recorded under the same conditions.

Conformational search and simulations of ECD spectra

The conformational search was carried out using CONFLEX 7 software¹³ with the MMFF94s force fields within 10 kcal mol^{-1} energy window. Next, all the obtained structures were submitted to the Gaussian16 (version C.01) program for DFT re-optimisation at the B97XD/6-311+G(d,p) using PCM model for CH_3CN . All conformers were confirmed to contain no imaginary frequencies. The final structures within 1.5 kcal mol^{-1} energy window were selected for subsequent simulations of ECD spectra. Boltzmann populations were calculated at 298 K. Theoretical ECD/UV spectra were simulated at the CAM-B3LYP/def2-TZVP level using the PCM model for CH_3CN . Furthermore, the ECD spectra were calculated using aug-cc-pVDZ basis set with B3LYP functional; the obtained results are similar to CAM-B3LYP/def2-TZVP. Calculations were performed for the first 50 excited electronic states. Rotatory strengths were calculated using both the length and the velocity formalisms. The differences between these two were less than 5%, so only the velocity representations (R_{vel}) were taken into account. The UV correction was applied according the experimental data recorder under the same conditions as mentioned beforehand.

Conflicts of interest

There are no conflicts to declare.
