# Synthesis of heteroatom-containing pyrrolidine derivatives based on Ti(O-iPr)<sub>4</sub> and EtMgBr-catalyzed carbocyclization of allylpropargyl amines with Et<sub>2</sub>Zn†

Rita N. Kadikova, \*\*D\* Ilfir R. Ramazanov, Azat M. Gabdullin, Oleg S. Mozgovoj and Usein M. Dzhemilev

The  $Ti(O-iPr)_4$  and EtMgBr-catalyzed regio and stereoselective carbocyclization of N-allyl-substituted 2-alkynylamines with  $Et_2Zn$ , followed by deuterolysis or hydrolysis, affords the corresponding methylenepyrrolidine derivatives in high yields. It was found that Ti-Mg-catalyzed carbocyclization of N-allyl-substituted 2-alkynylamines with  $Et_2Zn$  is equally selective in dichloromethane, hexane, toluene, and diethyl ether. The reaction was tolerant to the presence of aryl, alkyl, trimethylsilyl, methoxymethyl and aminomethyl substituents on the alkyne. A selective method was proposed for the preparation of bispyrrolidine derivatives using Ti-Mg-catalyzed carbocyclization of bis-allylpropargyl amines with  $Et_2Zn$ .

# Introduction

Five- and six-membered nitrogen-containing heterocycles are frequently encountered structural elements of lots of natural and biologically active compounds,1-4 such as pyrrolizidine alkaloids5,6 and carbapenems.<sup>7,8</sup> For example, nitrogen heterocycles with an aryl moiety in the  $\beta$ - or  $\gamma$ -position relative to nitrogen are of considerable interest as neuroactive compounds, as they are conformational constrained analogues of neurotransmitters such as serotonin and dopamine and opiate receptor ligands. 9,10 Of particular interest are 3-benzylpyrrolidine derivatives exhibiting biological activities such as protein kinase C inhibitors, 11,12 NK-3 receptor antagonists,13 and dopamine receptor antagonists.14 Thus, development of new efficient synthetic routes to five- and six-membered heterocycles is an important task. Transition metal-catalyzed cyclization of enynes is an efficient tool for the design of carbo and heterocyclic compounds.15-17 One of the earliest approach to intramolecular cyclization of enynes and substituted N-allylpropargylamines consists in the use of lowvalent zirconium complexes generated by treating Cp2ZrCl2 with Mg and HgCl<sub>2</sub>, or 2 equiv. of alkyllithium, such as n-BuLi, or a Grignard reagent, such as EtMgBr. 18,19 Low-valent iron complexes generated using Et2Zn were also active towards carbocyclization of activated enynes.20 A known method for the preparation of acyl-substituted pyrrolidines is Me<sub>2</sub>Zn/Ni(0)promoted cyclization of nitrogen-containing alkynyl enones.21

Institute of Petrochemistry and Catalysis of Russian Academy of Sciences, 141 Prospekt Oktyabrya, Ufa 450075, Russian Federation. E-mail: kadikritan@gmail.com

The cyclization of N-allyl-N-benzyl-3-(trimethylsilyl)-2-propynylamine on treatment with triallylmanganate is not stereoselective and gives a 1:1 mixture of Z/E isomers in 55% overall yield.22 Meanwhile, the reaction of N-benzyl-N-(3-(trimethylsilyl)prop-2yn-1-yl)prop-2-en-1-amine with four equivalents of methallylmagnesium chloride in the presence of catalytic amounts of CrCl<sub>3</sub> is stereoselective, giving the E-isomer in 73% yield.<sup>23</sup> The synthesis of acyl-substituted pyrrolidine derivatives with an exocyclic double bond by treatment of allyl-substituted propargylamines with methylmanganese carbonyl complex was reported.24 An unusual Pd(II)-catalyzed carbocyclization of nitrogencontaining 1,6-enynes accompanied by Pd-initiated migration of β-hydrogen to give 1,3- and 1,4-dienes was described.25 Palladiumcatalyzed intramolecular cyclization of nitrogen-containing enypyl acetate in the presence of ZnCl<sub>2</sub> followed by cross-coupling with alkenylstannane results in the selective formation of pyrrolidine derivative.26 A pyrrolidine derivative with a conjugated double bond is formed in a similar way upon Pd-catalyzed reaction of nitrogen-containing acetoxyenyne with tris(isopropenyl)indium.<sup>27</sup> An example involving low-valent titanium complex is the reaction of the Sato reagent, (η²-propene)Ti(O-i-Pr)<sub>2</sub> (obtained from Ti(O-i- $Pr)_4$  and *i*-PrMgCl in 1 : 2 ratio), with N-(4-methylbenzyl)-N-(prop-2-yn-1-yl)prop-2-en-1-amine with a terminal double bond giving the cyclization product in 53% yield.28 Now we demonstrate that the reaction of N,N-dialkyl-substituted 2-alkynylamines with Et<sub>2</sub>Zn catalyzed by the Ti(i-OPr)<sub>4</sub>-EtMgBr system results in the selective formation of 2-zincoethylzincation products.28,29 Relying on analysis of the above literature, we assumed that Ti-Mg-catalyzed carbozincation of functionalized allyl-substituted propargylamines could serve for the development of selective one-pot methods for the synthesis of various methylenepyrrolidine

derivatives. As a continuation of research on the Ti-Mg-catalyzed carbozincation of functionally substituted alkyne substrates, we studied here carbocyclization of a variety of allyl-substituted propargylamines.

Previously, we have showed that Zr-catalyzed carbocyclization of dialkyl-substituted propargylamines results in the selective formation of products of 2-aluminum ethylalumination in high yields. We were interested in studying the behavior of allyl-substituted propargylamines towards Zr-catalyzed cycloalumination. However, after 24 hours of the reaction of N-(4-methoxybenzyl)-N-(3-(trimethylsilyl)prop-2-yn1-yl)prop-2-en-1-amine, prepared from ethynyltrimethylsilane and N-(4-methoxybenzyl)prop-2-en-1-amine,  $^{31}$  with 3 equivalents of Et<sub>3</sub>Al in the presence of 20 mol% Cp<sub>2</sub>ZrCl<sub>2</sub> in hexane at 40 °C, the yield of the carbocyclization product did not exceed 5–10% (Scheme 1).

The increase in the amount of Et<sub>3</sub>Al taken in the reaction to 6 equivalents and increase in the reaction time to 3 days did not result in higher yields of the target product. The observed low conversion of the nitrogen-containing substrate may be attributable to steric and electronic factors involved in the coordination of low-valent Cp<sub>2</sub>Zr to a enyne molecule.<sup>30</sup> It should be borne in mind that coordination of the Et<sub>3</sub>Al aluminum atom to the nitrogen lone pair may not only decrease the triple bond nucleophilicity, but also generate additional steric hindrance for coupling of the olefinic and acetylenic moieties of the enyne substrate with the zirconium atom bearing bulky cyclopentadienyl ligand. The steric hindrance arising at the stage of coupling of the olefinic and acetylenic enyne moieties with the low-valent zirconocene may also be enhanced due to the presence of bulky benzyl substituent at the nitrogen atom.

### Results and discussion

We found that the reaction of N-allyl-substituted propargylamines 1 with 2.5 equivalents of Et<sub>2</sub>Zn (1 M in hexane) in the presence of 15 mol% of Ti(O-iPr)<sub>4</sub> (0.5 M in hexane) and 20 mol% of EtMgBr (2.5 M in Et<sub>2</sub>O) conducted in dichloromethane at room temperature for 18 hours gives, after deuterolysis or hydrolysis, methylenepyrrolidine derivatives 3 and 4 with Z-configuration of the double bond (Scheme 2). The structure of the resulting methylenepyrrolidine derivatives was established by 1D and 2D NMR spectroscopy of products of their hydrolysis 3a-g,i and deuterolysis 4h,f (Scheme 2). The Zconfiguration of the double bond of 3-methyl-4-

Scheme 2 Ti-Mg-catalyzed carbocyclization of allyl substituted propargylamines with  $Et_2Zn$  in  $CH_2Cl_2$ .

3i (91%)

5h (61%)

methylenepyrrolidines 3a-3g, 3i, 4h,f was established by NOESY experiments. For example, the NOESY spectra of 3a and 3b clearly show the cross-peaks between the hydrogen atom at the double bond ( $\delta=5.31$  and  $\delta=6.32$ , respectively) and the hydrogen atoms of the methyl substituent ( $\delta=1.09$  and  $\delta=1.30$ , respectively) of the pyrrolidine ring, that indicates the formation of Z-diastereomers in the reaction mixtures. The selective formation of methylenepyrrolidine derivatives 3 and 4 with the Z-configuration of the double bond is supported by the mechanism of the Ti-Mg-catalyzed allylpropargyl amines carbometallation reaction using  $Et_2Zn$  (the mechanism is described below in Scheme 7).

Our study demonstrated that the presence of furan (3e), thiophene (3f), *para*-methoxybenzyl (3a), and *para*-chlorobenzyl (3b) substituents at nitrogen atom does not prevent regio and stereoselective carbocyclization of enynes on treatment with  $Et_2Zn$  in the presence of catalytic amounts of  $Ti(O-iPr)_4$  and EtMgBr.

The carbocyclization of enynes with an aryl (3b, 3c, 3i), trimethylsilyl (3a, 3e, 3f, 3g, 4h, 5a), or butyl (3d) substituent at the triple bond is equally regio and stereoselective. The presence of two deuterium atoms (4h) or two iodine atoms (5a,h) in the

Paper **RSC Advances** 

methylenepyrrolidine molecules obtained after deuterolysis and iodinolysis attests to the oganometallic nature of intermediate 2. Similarly, Ti-Mg-catalyzed carbocyclization of nonactivated and oxygen-containing enynes with Et<sub>2</sub>Zn proceeds.<sup>32</sup> To our surprise, the reaction of the organozinc intermediate 2 with I2 leads to the selective formation of diiodo-substituted pyrrolidin-2-ones - cyclic amides 5a,h. It should be noted that tertiary cyclic amides are widespread structural units of many pharmaceuticals, such as lenalidomide, piperine, evodiamine, diazepam, etc.33-37 It is known that the alpha-carbon atom of tertiary amines can by easily oxidized to a carbonyl group under the action of such oxidizing agents as iodosobenzene, PhCO<sub>3</sub>-<sup>t</sup>Bu, <sup>t</sup>BuOOH and RuO<sub>2</sub>/NaIO<sub>4</sub>, <sup>38-42</sup> as well as under the action of O2 in the presence of Ru-, Au-, Fe- and Cu-containing catalysts. 43-47 However, the mechanism of the formation of the substituted pyrrolidin-2-ones 5a,h in our case will be the subject of our futher study. This issue deserves special consideration, as the obtained transformation is selective method for the preparation of cyclic amides of different structures. Thus, Ti-Mgcatalyzed carbocyclization of nitrogen-containing envnes on treatment with Et2Zn has benefits such as tolerance to bulky groups in the unsaturated substrate molecule and the possibility of carbometallation of enynes with a variety of heterofunctional substituents.

It is known that the reaction of Sato reagent ( $\eta^2$ -propene) Ti(Oi-Pr)<sub>2</sub> (obtained from Ti(Oi-Pr)<sub>4</sub> and i-PrMgCl in a ratio of 1:2) with N-(4-methylbenzyl)-N-(prop-2-yn-1-yl)prop-2-en-1amine that has a terminal triple bond, gives a cyclization product with 53% yield.25 However, our attempts to cyclize the 1,6-enynes described in the article using one equivalent of Ti(Oi-Pr)<sub>4</sub> and two equivalents of EtMgBr in the absence of Et<sub>2</sub>Zn led to the non-selective formation of a mixture of unidentified reaction products. The reaction of 1,6-enynes with 2 equivalents of EtMgBr in the presence of catalytic amounts of Ti(Oi-Pr)4 does not occur. Using a stoichiometric amount of Et<sub>2</sub>Zn and catalytic amounts of Ti(Oi-Pr)4 and EtMgBr the reaction gave only one reaction product in high yield. The question of the reasons for this selectivity is complex and we do not have enough data to provide a convincing theory. However coordination effects play a significant role in the reaction under study. So, the conversion of 2-alkynylamines and 1-alkynylphosphines<sup>28</sup> is excellent, but the reaction with decyne-5 proceeds poorly. Further, the reaction goes well in Et<sub>2</sub>O, CH<sub>2</sub>Cl<sub>2</sub>, hexane, toluene, benzene and anisole but does not proceed in 1,4dioxane, tetrahydrofuran, 1,2-dichloroethane, 1,2-dimethoxyethane, chloroform, and triethylamine.29

We studied carbocyclization of nitrogen-containing enynes in various solvents. At the same time, it must be taken into account that hexane (Et<sub>2</sub>Zn (1 M in hexane) and Ti(O-iPr)<sub>4</sub> (0.5 M in hexane)), and Et<sub>2</sub>O (EtMgBr (2.5 M in Et<sub>2</sub>O)) are always present in the reaction mixture. Quite recently, we reported that Ti-Mg-catalyzed 2-zincoethylzincation of substituted 2-alkynylamines with Et<sub>2</sub>Zn proceeds equally selectively in diethyl ether, anisole, dichloromethane, hexane, benzene, and toluene.29 In this study, we found that the formation of carbocyclization product 4f upon the reaction of N-(thiophen-2-ylmethyl)-N-(3-(trimethylsilyl)prop-2-yn-1-yl)prop-2-en-1-amine 1f with 2.5

Scheme 4 Ti-Mg-catalyzed carbocyclization of N,N'-(1,4-phenylenebis(methylene))bis(N-(3-(trimethylsilyl)prop-2-yn-1-yl)prop-2-en-1-amine) with Et<sub>2</sub>Zn in CH<sub>2</sub>Cl<sub>2</sub>.

equivalents of Et<sub>2</sub>Zn in the presence of 15 mol% of Ti(O-iPr)<sub>4</sub>, (0.5 M in hexane) and 20 mol% of EtMgBr (2.5 M in Et<sub>2</sub>O) is regio and stereoselective not only in dichloromethane (as shown in Scheme 2), but also in diethyl ether, hexane, and toluene (Scheme 3).

We obtained bis-methylenepyrrolidine derivative 7 by the reaction of N,N'-(1,4-phenylenebis(methylene))bis(N-(3-(trimethylsilyl) prop-2-yn-1-yl)prop-2-en-1-amine) 6 with 5 equivalents of Et<sub>2</sub>Zn in

5 Ti-Mg-catalyzed carbocyclization of  $N^1, N^{10}$ -diallyl- $N^{1}$ ,  $N^{10}$ -bis(4-methylbenzyl)deca-2,8-diyne-1,10-diamine with Et<sub>2</sub>Zn in CH<sub>2</sub>Cl<sub>2</sub>.

$$\begin{array}{c} R \\ 1M \text{ in hexanes} \\ 1H \text{ in hexan$$

Scheme 6 Ti–Mg-catalyzed carbocyclization of allyl substituted but-2-yne-1,4-diamines and N-allyl-substituted of oxygen-containing but-2-yn-1-amine with Et<sub>2</sub>Zn in CH<sub>2</sub>Cl<sub>2</sub>.

the presence of 30 mol% of  $Ti(O-iPr)_4$ , (0.5 M in hexane) and 40 mol% of EtMgBr (2.5 M in  $Et_2O$ ) in dichloromethane (Scheme 4).

We also succeeded to perform the carbocyclization of  $N^1$ , $N^{10}$ -diallyl- $N^1$ , $N^{10}$ -bis(4-methylbenzyl)deca-2,8-diyne-1,10-diamine **8**, prepared from 1,7-octadiyne, to give bis-methylenepyrrolidine derivative **9** (1,6-bis(4-methyl-1-(4-methylbenzyl)pyrrolidin-3-ylidene)hexane) (Scheme 5).

This study indicates that Ti-Mg-catalyzed carbocyclization of nitrogen-containing envnes with Et<sub>2</sub>Zn is equally efficient both for enynes with alkyl substituent at the triple bond (e.g., 3d and 9) and enynes with aryl and trimethylsilyl substituents at the triple bond (e.g., 3a-c, 3e-g, 3i, 4h,f, 5a,h). For example, it is known that cyclization of unfunctionalized enynes in the course of the Cp<sub>2</sub>ZrCl<sub>2</sub>-catalyzed cycloalumination occurs selectively if directing groups such as phenyl or trimethylsilyl group are present at the triple bond.48 Perhaps, the agostic interaction between the ortho-hydrogen atom of the phenyl group, 49 or the trimethylsilyl group, and the zirconium atom may be a favorable factor promoting the cyclization of enynes in the course of cycloalumination. From this standpoint, it was of interest to study the Ti-Mg-catalyzed reaction of Et2Zn with nitrogencontaining 1,6-enynes containing additional heterofunctional substituents at the triple bond. Carbocyclization of enynes with a bifunctionally substituted triple bond may serve, in the future, for the development of one-pot syntheses of polyfunctionalized pyrrolidine derivatives. Additionally, study of the behavior of these envne substrates towards carbocyclization would shed light on the electronic and steric effects of substituents at the triple bond in the reaction. We found that the reaction of Nallyl-substituted but-2-yn-1,4-diamines 10 with 2.5 equivalents of Et<sub>2</sub>Zn in the presence of 15 mol% of Ti(O-iPr)<sub>4</sub>, (0.5 M in hexane) and 20 mol% of EtMgBr (2.5 M in Et<sub>2</sub>O) in

Scheme 7 Putative mechanism of Ti-Mg-catalyzed reaction of allyl substituted but-2-yn-1,4-diamines with Et<sub>2</sub>Zn.

dichloromethane results in the regio and stereoselective formation of carbocyclization products **11** and **12** in high yields (Scheme 6). Thus, the presence of the second aminomethyl group at the triple bond in the nitrogen-containing enyne molecules **10** does not prevent the intramolecular cyclization.

The reaction of acetylenic ether **13** with 2.5 equivalents of  $\operatorname{Et_2Zn}$  in the presence of 15 mol% of  $\operatorname{Ti}(O-i\Pr)_4$ , (0.5 M in hexane) and 20 mol% of  $\operatorname{EtMgBr}$  (2.5 M in  $\operatorname{Et_2O}$ ) in dichloromethane results in regio and stereoselective formation of methoxy-substituted pyrrolidine derivative **14** (Scheme 6). It is worth noting that, unlike N,N-dialkyl substituted 2-alkynylamines, substituted acetylenic alcohols and their ethers are unreactive towards  $\operatorname{Ti-Mg-catalyzed}$  2-zincoethylzincation. <sup>28,29</sup>

According to the reaction scheme that we proposed (Scheme 7), ligand exchange between  $Ti(O-iPr)_4$  and EtMgBr gives  $(O-iPr)_2TiEt_2$ , which is converted to titanium(II)—ethylene complex (titanacyclopropane intermediate). The displacement of ethylene from the titanium coordination sphere by a enyne molecule affords intermediate complex **A**. The subsequent coupling of the acetylene and ethylene moieties of the enyne molecule gives titanacyclopentene intermediate **B**, which undergoes transmetallation with  $Et_2Zn$  to be converted to organozinc intermediate **C**. The deuterolysis (or hydrolysis) of the latter furnishes the pyrrolidine derivative.

# Conclusions

We report a regio and stereoselective  $Ti(O-iPr)_4$  and EtMgBr-catalyzed carbocyclization of allyl propargyl amines with  $Et_2Zn$ . It was demonstrated that the presence of amine and ether groups at the enyne triple bond does not prevent

Paper RSC Advances

carbocyclization of allyl-substituted 2-alkynylamines. The study resulted in the development of an efficient method for the synthesis of a variety of heteroatom-containing pyrrolidine derivatives *via* organozinc synthesis. The observed tolerance of the Ti–Mg-catalyzed carbocyclization of enynes to the presence of various heterofunctional substituents opens prospects for further use of organozinc synthesis to develop one-pot syntheses of polyfunctional pyrrolidine derivatives. In connection with the obtained carbocyclization reaction we plan to develop an effective method for preparing methylenepiperidine derivatives based on Ti–Mg-catalyzed carbocyclization of *N*-homoallyl substituted 2-alkynylamines.

# **Experimental section**

### **General information**

The reagents were obtained from Sigma-Aldrich or Acros. Hexane and dichloromethane were distilled over P2O5. Diethyl ether, tetrahydrofuran, 1,4-dioxane, toluene, benzene and anisole were dried over sodium. Dried 1,2-dimethoxyethane was obtained from Sigma-Aldrich. 2-Alkynylamines 1a-i and 6, 8 were prepared by aminomethylation of terminal alkynes with aqueous formaldehyde and secondary N-aryl-substituted allyl amines under CuBr catalysis.<sup>50</sup> Nitrogen-containing 1,6-enynes with terminal propargyl and allyl groups were prepared by alkylation of N-aryl-substituted allyl amines with propargyl bromide under NaH.51 Allyl substituted but-2-yne-1,4-diamines 10 were prepared by aminomethylation of nitrogen-containing 1,6-enynes (with terminal propargyl and allyl groups) by bisamine.52 Acetylenic ethers 13 were prepared by aminomethylation of ethers of acetylenic alcohols with aqueous formaldehyde and secondary N-aryl-substituted allyl amines

Anal. calcd for  $C_{17}H_{24}D_2N_2$ , (%): C, 78.41; N, 10.76. Found, %: C, 78.48; N, 11.08.

(*Z*)-3-(5-Methoxypentylidene)-4-methyl-1-(4-methylbenzyl) pyrrolidine (14). Using the procedure described above *N*-allyl-7-methoxy-*N*-(4-methylbenzyl)hept-2-yn-1-amine (570 mg, 2 mmol) and  $H_2O$  (instead of  $D_2O$ )gave crude product that was purified by column chromatography (diethyl ether: isopropyl alcohol: hexane = 1:1:8) to afford 14 (517 mg, 90%).  $R_f$  0.63.

<sup>1</sup>H NMR (500 MHz, CDCl<sub>3</sub>):  $\delta$  = 1.08 (d, J = 7 Hz, 3H, C(6)H<sub>3</sub>), 1.42 (p, J = 8 Hz, 2H, C(15)H<sub>2</sub>), 1.58 (p, J = 8 Hz, 2H, C(16)H<sub>2</sub>), 1.95 (q, J = 7 Hz, 2H, C(14)H<sub>2</sub>), 2.03 (t, J = 8 Hz, 1H(A), C(1)H<sub>2</sub>), 2.37 (s, 3H, C(19)H<sub>3</sub>), 2.96 (d, J = 13 Hz, 1H(A), C(4)H<sub>2</sub>), 2.99 (t, J = 8 Hz, C(1)H<sub>2</sub>), 3.34 (s, 3H, C(18)H<sub>3</sub>), 3.37 (t, J = 7 Hz, 2H, C(17) H<sub>2</sub>), 3.47 (d, J = 13 Hz, 1H(B), C(4)H<sub>2</sub>), 3.59 (d, J = 13 Hz, 1H(A), C(7)H<sub>2</sub>), 3.64 (d, J = 13 Hz, 1H(B), C(7)H<sub>2</sub>), 5.14 (m, 1H, C(5)H), 7.15 (d, J = 8 Hz, 2H, C(10, 12)H), 7.26 (d, J = 8 Hz, 2H, C(9, 13) H).

 $^{13}\text{C-}\{^1\text{H}\}$  NMR (500 MHz, CDCl<sub>3</sub>):  $\delta=17.68$  (C(6)), 21.12 (C(19)), 26.08 (C(15)), 29.20 (C(14)), 29.25 (C(16)), 37.30 (C(2)), 56.73 (C(4)), 58.55 (C(18)), 60.54 (C(7)), 62.22 (C(1)), 119.43 (C(5)), 128.77 (C(9, 13)), 128.93 (C(10, 12)), 135.95 (C(8)), 136.47 (C(11)), 144.32 (C(3)).

MS (EI): m/z, % = 287 (18) [M $^{+}$ ], 200 (38), 105 (100), 79 (9). Anal. calcd for  $C_{19}H_{29}NO$ , (%): C, 79.39; H, 10.17; N, 4.87. Found, %: C, 79.11; H, 10.00; N, 4.53.
