# Synthesis of heteroatom-containing pyrrolidine derivatives based on $\text{Ti}(\text{O-}i\text{Pr})_4$ and $\text{EtMgBr}$ -catalyzed carbocyclization of allylpropargyl amines with $\text{Et}_2\text{Zn}^\dagger$

 Rita N. Kadikova,<sup>✉\*</sup> Ilfir R. Ramazanov, Azat M. Gabdullin, Oleg S. Mozgovoj and Usein M. Dzhemilev

The  $\text{Ti}(\text{O-}i\text{Pr})_4$  and  $\text{EtMgBr}$ -catalyzed regio and stereoselective carbocyclization of *N*-allyl-substituted 2-alkynylamines with  $\text{Et}_2\text{Zn}$ , followed by deuterolysis or hydrolysis, affords the corresponding methylenepyrrolidine derivatives in high yields. It was found that Ti–Mg-catalyzed carbocyclization of *N*-allyl-substituted 2-alkynylamines with  $\text{Et}_2\text{Zn}$  is equally selective in dichloromethane, hexane, toluene, and diethyl ether. The reaction was tolerant to the presence of aryl, alkyl, trimethylsilyl, methoxymethyl and aminomethyl substituents on the alkyne. A selective method was proposed for the preparation of bis-pyrrolidine derivatives using Ti–Mg-catalyzed carbocyclization of bis-allylpropargyl amines with  $\text{Et}_2\text{Zn}$ .

## Introduction

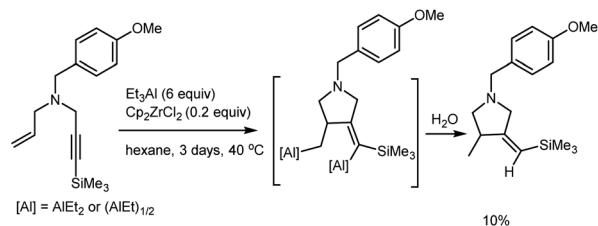

Five- and six-membered nitrogen-containing heterocycles are frequently encountered structural elements of lots of natural and biologically active compounds,<sup>1–4</sup> such as pyrrolizidine alkaloids<sup>5,6</sup> and carbapenems.<sup>7,8</sup> For example, nitrogen heterocycles with an aryl moiety in the  $\beta$ - or  $\gamma$ -position relative to nitrogen are of considerable interest as neuroactive compounds, as they are conformational constrained analogues of neurotransmitters such as serotonin and dopamine and opiate receptor ligands.<sup>9,10</sup> Of particular interest are 3-benzylpyrrolidine derivatives exhibiting biological activities such as protein kinase C inhibitors,<sup>11,12</sup> NK-3 receptor antagonists,<sup>13</sup> and dopamine receptor antagonists.<sup>14</sup> Thus, development of new efficient synthetic routes to five- and six-membered heterocycles is an important task. Transition metal-catalyzed cyclization of enynes is an efficient tool for the design of carbo and heterocyclic compounds.<sup>15–17</sup> One of the earliest approach to intramolecular cyclization of enynes and substituted *N*-allylpropargylamines consists in the use of low-valent zirconium complexes generated by treating  $\text{Cp}_2\text{ZrCl}_2$  with Mg and  $\text{HgCl}_2$ , or 2 equiv. of alkyllithium, such as *n*-BuLi, or a Grignard reagent, such as  $\text{EtMgBr}$ .<sup>18,19</sup> Low-valent iron complexes generated using  $\text{Et}_2\text{Zn}$  were also active towards carbocyclization of activated enynes.<sup>20</sup> A known method for the preparation of acyl-substituted pyrrolidines is  $\text{Me}_2\text{Zn}/\text{Ni}(0)$ -promoted cyclization of nitrogen-containing alkyne enones.<sup>21</sup>

The cyclization of *N*-allyl-*N*-benzyl-3-(trimethylsilyl)-2-propynylamine on treatment with triallylmanganate is not stereoselective and gives a 1 : 1 mixture of *Z/E* isomers in 55% overall yield.<sup>22</sup> Meanwhile, the reaction of *N*-benzyl-*N*-(3-(trimethylsilyl)prop-2-yn-1-yl)prop-2-en-1-amine with four equivalents of methylmagnesium chloride in the presence of catalytic amounts of  $\text{CrCl}_3$  is stereoselective, giving the *E*-isomer in 73% yield.<sup>23</sup> The synthesis of acyl-substituted pyrrolidine derivatives with an exocyclic double bond by treatment of allyl-substituted propargylamines with methylmanganese carbonyl complex was reported.<sup>24</sup> An unusual Pd(II)-catalyzed carbocyclization of nitrogen-containing 1,6-enynes accompanied by Pd-initiated migration of  $\beta$ -hydrogen to give 1,3- and 1,4-dienes was described.<sup>25</sup> Palladium-catalyzed intramolecular cyclization of nitrogen-containing enynyl acetate in the presence of  $\text{ZnCl}_2$  followed by cross-coupling with alkenylstannane results in the selective formation of pyrrolidine derivative.<sup>26</sup> A pyrrolidine derivative with a conjugated double bond is formed in a similar way upon Pd-catalyzed reaction of nitrogen-containing acetoxyenyne with tris(isopropenyl)indium.<sup>27</sup> An example involving low-valent titanium complex is the reaction of the Sato reagent,  $(\eta^2\text{-propene})\text{Ti}(\text{O-}i\text{Pr})_2$  (obtained from  $\text{Ti}(\text{O-}i\text{Pr})_4$  and *i*-PrMgCl in 1 : 2 ratio), with *N*-(4-methylbenzyl)-*N*-(prop-2-yn-1-yl)prop-2-en-1-amine with a terminal double bond giving the cyclization product in 53% yield.<sup>28</sup> Now we demonstrate that the reaction of *N,N*-dialkyl-substituted 2-alkynylamines with  $\text{Et}_2\text{Zn}$  catalyzed by the  $\text{Ti}(i\text{-OPr})_4$ – $\text{EtMgBr}$  system results in the selective formation of 2-zincoethylzincation products.<sup>28,29</sup> Relying on analysis of the above literature, we assumed that Ti–Mg-catalyzed carbocyclization of functionalized allyl-substituted propargylamines could serve for the development of selective one-pot methods for the synthesis of various methylenepyrrolidine

**Scheme 1** Ti–Mg-catalyzed reaction of *N*-(4-methoxybenzyl)-*N*-(3-(trimethylsilyl)prop-2-yn-1-yl)prop-2-en-1-amine with  $\text{Et}_2\text{Zn}$ .

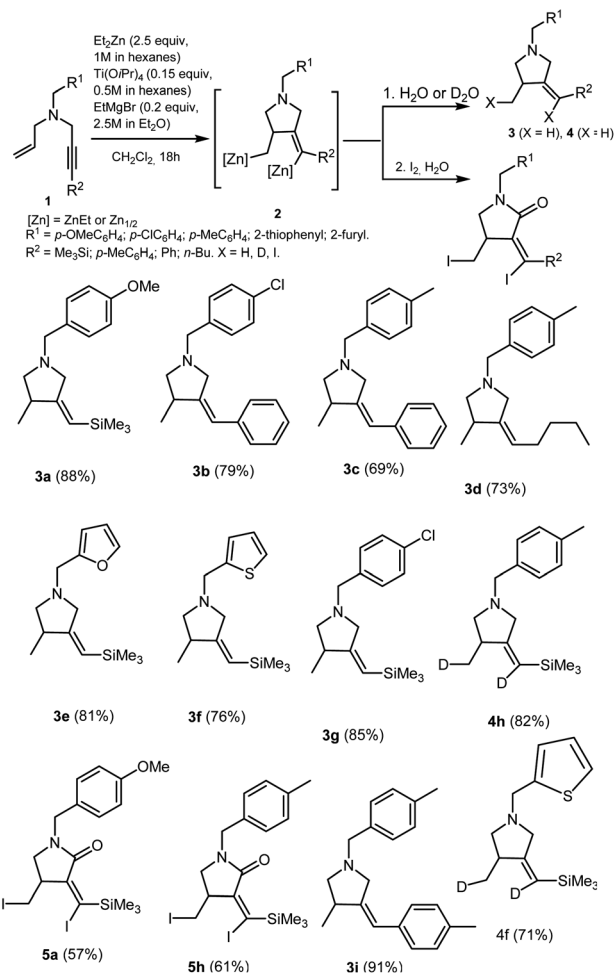

derivatives. As a continuation of research on the Ti–Mg-catalyzed carbocyclization of functionally substituted alkyne substrates, we studied here carbocyclization of a variety of allyl-substituted propargylamines.

Previously, we have showed that Zr-catalyzed carbocyclization of dialkyl-substituted propargylamines results in the selective formation of products of 2-aluminum ethyl-alumination in high yields.<sup>30</sup> We were interested in studying the behavior of allyl-substituted propargylamines towards Zr-catalyzed cycloalumination. However, after 24 hours of the reaction of *N*-(4-methoxybenzyl)-*N*-(3-(trimethylsilyl)prop-2-yn-1-yl)prop-2-en-1-amine, prepared from ethynyltrimethylsilane and *N*-(4-methoxybenzyl)prop-2-en-1-amine,<sup>31</sup> with 3 equivalents of  $\text{Et}_3\text{Al}$  in the presence of 20 mol%  $\text{Cp}_2\text{ZrCl}_2$  in hexane at 40 °C, the yield of the carbocyclization product did not exceed 5–10% (Scheme 1).

The increase in the amount of  $\text{Et}_3\text{Al}$  taken in the reaction to 6 equivalents and increase in the reaction time to 3 days did not result in higher yields of the target product. The observed low conversion of the nitrogen-containing substrate may be attributable to steric and electronic factors involved in the coordination of low-valent  $\text{Cp}_2\text{Zr}$  to a enyne molecule.<sup>30</sup> It should be borne in mind that coordination of the  $\text{Et}_3\text{Al}$  aluminum atom to the nitrogen lone pair may not only decrease the triple bond nucleophilicity, but also generate additional steric hindrance for coupling of the olefinic and acetylenic moieties of the enyne substrate with the zirconium atom bearing bulky cyclopentadienyl ligand. The steric hindrance arising at the stage of coupling of the olefinic and acetylenic enyne moieties with the low-valent zirconocene may also be enhanced due to the presence of bulky benzyl substituent at the nitrogen atom.

## Results and discussion

We found that the reaction of *N*-allyl-substituted propargylamines **1** with 2.5 equivalents of  $\text{Et}_2\text{Zn}$  (1 M in hexane) in the presence of 15 mol% of  $\text{Ti}(\text{O}-i\text{Pr})_4$  (0.5 M in hexane) and 20 mol% of  $\text{EtMgBr}$  (2.5 M in  $\text{Et}_2\text{O}$ ) conducted in dichloromethane at room temperature for 18 hours gives, after deuteration or hydrolysis, methylenepyrrolidine derivatives **3** and **4** with *Z*-configuration of the double bond (Scheme 2). The structure of the resulting methylenepyrrolidine derivatives was established by 1D and 2D NMR spectroscopy of products of their hydrolysis **3a–g,i** and deuteration **4h,f** (Scheme 2). The *Z*-configuration of the double bond of 3-methyl-4-

**Scheme 2** Ti–Mg-catalyzed carbocyclization of allyl substituted propargylamines with  $\text{Et}_2\text{Zn}$  in  $\text{CH}_2\text{Cl}_2$ .

methylenepyrrolidines **3a–3g**, **3i**, **4h,f** was established by NOESY experiments. For example, the NOESY spectra of **3a** and **3b** clearly show the cross-peaks between the hydrogen atom at the double bond ( $\delta = 5.31$  and  $\delta = 6.32$ , respectively) and the hydrogen atoms of the methyl substituent ( $\delta = 1.09$  and  $\delta = 1.30$ , respectively) of the pyrrolidine ring, that indicates the formation of *Z*-diastereomers in the reaction mixtures. The selective formation of methylenepyrrolidine derivatives **3** and **4** with the *Z*-configuration of the double bond is supported by the mechanism of the Ti–Mg-catalyzed allylpropargyl amines carbometallation reaction using  $\text{Et}_2\text{Zn}$  (the mechanism is described below in Scheme 7).

Our study demonstrated that the presence of furan (**3e**), thiophene (**3f**), *para*-methoxybenzyl (**3a**), and *para*-chlorobenzyl (**3b**) substituents at nitrogen atom does not prevent regio and stereoselective carbocyclization of enynes on treatment with  $\text{Et}_2\text{Zn}$  in the presence of catalytic amounts of  $\text{Ti}(\text{O}-i\text{Pr})_4$  and  $\text{EtMgBr}$ .

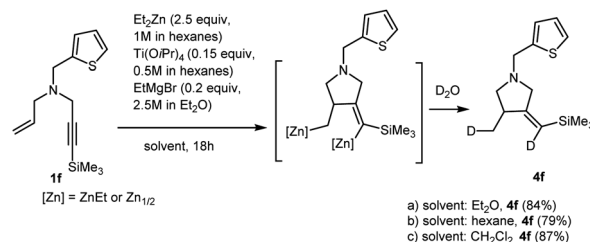

The carbocyclization of enynes with an aryl (**3b**, **3c**, **3i**), trimethylsilyl (**3a**, **3e**, **3f**, **3g**, **4h**, **5a**), or butyl (**3d**) substituent at the triple bond is equally regio and stereoselective. The presence of two deuterium atoms (**4h**) or two iodine atoms (**5a,h**) in the

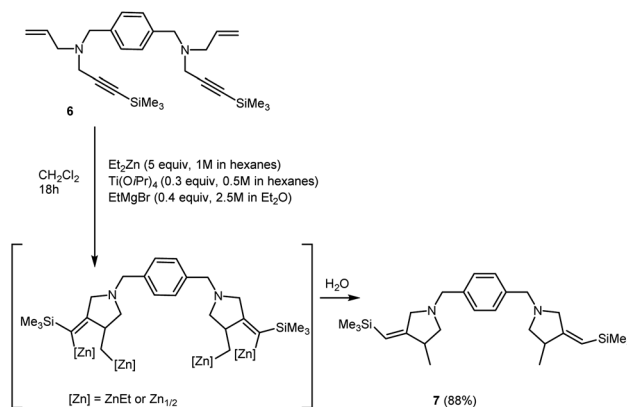

methylenepyrrolidine molecules obtained after deuteration and iodolysis attests to the organometallic nature of intermediate **2**. Similarly, Ti–Mg-catalyzed carbocyclization of non-activated and oxygen-containing enynes with  $\text{Et}_2\text{Zn}$  proceeds.<sup>32</sup> To our surprise, the reaction of the organozinc intermediate **2** with  $\text{I}_2$  leads to the selective formation of diiodo-substituted pyrrolidin-2-ones – cyclic amides **5a,h**. It should be noted that tertiary cyclic amides are widespread structural units of many pharmaceuticals, such as lenalidomide, piperine, evodiamine, diazepam, *etc.*<sup>33–37</sup> It is known that the alpha-carbon atom of tertiary amines can be easily oxidized to a carbonyl group under the action of such oxidizing agents as iodosobenzene,  $\text{PhCO}_3\text{-}^t\text{Bu}$ ,  $^t\text{BuOOH}$  and  $\text{RuO}_2/\text{NaIO}_4$ ,<sup>38–42</sup> as well as under the action of  $\text{O}_2$  in the presence of Ru-, Au-, Fe- and Cu-containing catalysts.<sup>43–47</sup> However, the mechanism of the formation of the substituted pyrrolidin-2-ones **5a,h** in our case will be the subject of our further study. This issue deserves special consideration, as the obtained transformation is selective method for the preparation of cyclic amides of different structures. Thus, Ti–Mg-catalyzed carbocyclization of nitrogen-containing enynes on treatment with  $\text{Et}_2\text{Zn}$  has benefits such as tolerance to bulky groups in the unsaturated substrate molecule and the possibility of carbometallation of enynes with a variety of heterofunctional substituents.

It is known that the reaction of Sato reagent ( $\eta^2$ -propene)  $\text{Ti}(\text{O}i\text{-Pr})_2$  (obtained from  $\text{Ti}(\text{O}i\text{-Pr})_4$  and  $i\text{-PrMgCl}$  in a ratio of 1 : 2) with  $N$ -(4-methylbenzyl)- $N$ -(prop-2-yn-1-yl)prop-2-en-1-amine that has a terminal triple bond, gives a cyclization product with 53% yield.<sup>25</sup> However, our attempts to cyclize the 1,6-enynes described in the article using one equivalent of  $\text{Ti}(\text{O}i\text{-Pr})_4$  and two equivalents of  $\text{EtMgBr}$  in the absence of  $\text{Et}_2\text{Zn}$  led to the non-selective formation of a mixture of unidentified reaction products. The reaction of 1,6-enynes with 2 equivalents of  $\text{EtMgBr}$  in the presence of catalytic amounts of  $\text{Ti}(\text{O}i\text{-Pr})_4$  does not occur. Using a stoichiometric amount of  $\text{Et}_2\text{Zn}$  and catalytic amounts of  $\text{Ti}(\text{O}i\text{-Pr})_4$  and  $\text{EtMgBr}$  the reaction gave only one reaction product in high yield. The question of the reasons for this selectivity is complex and we do not have enough data to provide a convincing theory. However coordination effects play a significant role in the reaction under study. So, the conversion of 2-alkynylamines and 1-alkynylphosphines<sup>28</sup> is excellent, but the reaction with decyne-5 proceeds poorly. Further, the reaction goes well in  $\text{Et}_2\text{O}$ ,  $\text{CH}_2\text{Cl}_2$ , hexane, toluene, benzene and anisole but does not proceed in 1,4-dioxane, tetrahydrofuran, 1,2-dichloroethane, 1,2-dimethoxyethane, chloroform, and triethylamine.<sup>29</sup>

We studied carbocyclization of nitrogen-containing enynes in various solvents. At the same time, it must be taken into account that hexane ( $\text{Et}_2\text{Zn}$  (1 M in hexane) and  $\text{Ti}(\text{O}i\text{-Pr})_4$  (0.5 M in hexane)), and  $\text{Et}_2\text{O}$  ( $\text{EtMgBr}$  (2.5 M in  $\text{Et}_2\text{O}$ )) are always present in the reaction mixture. Quite recently, we reported that Ti–Mg-catalyzed 2-zincoethylzincation of substituted 2-alkynylamines with  $\text{Et}_2\text{Zn}$  proceeds equally selectively in diethyl ether, anisole, dichloromethane, hexane, benzene, and toluene.<sup>29</sup> In this study, we found that the formation of carbocyclization product **4f** upon the reaction of  $N$ -(thiophen-2-ylmethyl)- $N$ -(3-(trimethylsilyl)prop-2-yn-1-yl)prop-2-en-1-amine **1f** with 2.5

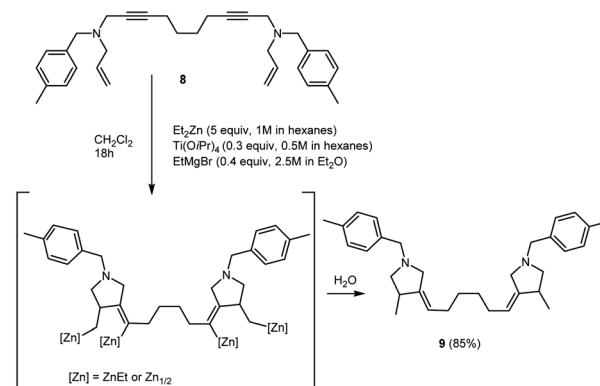

**Scheme 3** Ti–Mg-catalyzed carbocyclization reactions of  $N$ -(4-methylbenzyl)- $N$ -(3-(trimethylsilyl)prop-2-yn-1-yl)prop-2-en-1-amine with  $\text{Et}_2\text{Zn}$  in various solvents.

**Scheme 4** Ti–Mg-catalyzed carbocyclization of  $N,N'$ -(1,4-phenylenebis(methylene))bis( $N$ -(3-(trimethylsilyl)prop-2-yn-1-yl)prop-2-en-1-amine) with  $\text{Et}_2\text{Zn}$  in  $\text{CH}_2\text{Cl}_2$ .

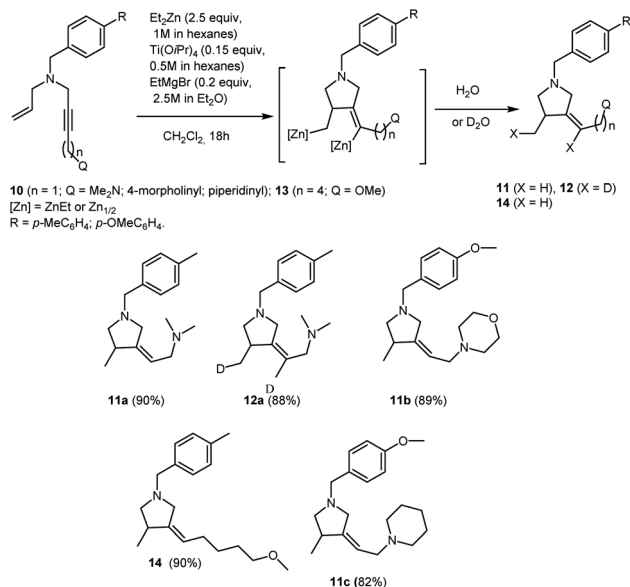

equivalents of  $\text{Et}_2\text{Zn}$  in the presence of 15 mol% of  $\text{Ti}(\text{O}i\text{-Pr})_4$ , (0.5 M in hexane) and 20 mol% of  $\text{EtMgBr}$  (2.5 M in  $\text{Et}_2\text{O}$ ) is regio and stereoselective not only in dichloromethane (as shown in Scheme 2), but also in diethyl ether, hexane, and toluene (Scheme 3).

We obtained bis-methylenepyrrolidine derivative **7** by the reaction of  $N,N'$ -(1,4-phenylenebis(methylene))bis( $N$ -(3-(trimethylsilyl)prop-2-en-1-yl)prop-2-en-1-amine) **6** with 5 equivalents of  $\text{Et}_2\text{Zn}$  in

**Scheme 5** Ti–Mg-catalyzed carbocyclization of  $N^1,N^{10}$ -diallyl- $N^1,N^{10}$ -bis(4-methylbenzyl)deca-2,8-diyne-1,10-diamine with  $\text{Et}_2\text{Zn}$  in  $\text{CH}_2\text{Cl}_2$ .

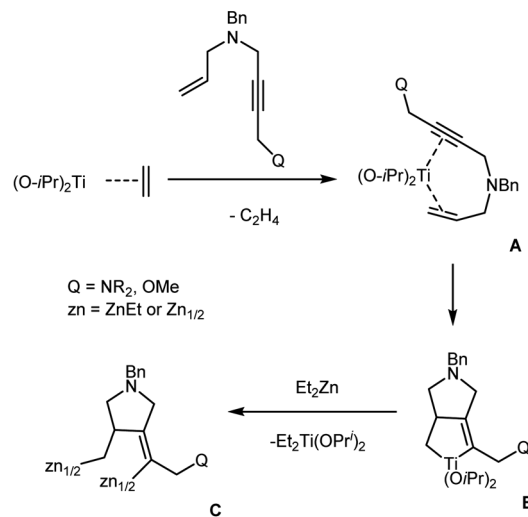

**Scheme 6** Ti–Mg-catalyzed carbocyclization of allyl substituted but-2-yne-1,4-diamines and *N*-allyl-substituted oxygen-containing but-2-yn-1-amine with  $\text{Et}_2\text{Zn}$  in  $\text{CH}_2\text{Cl}_2$ .

the presence of 30 mol% of  $\text{Ti}(\text{O-}i\text{Pr})_4$ , (0.5 M in hexane) and 40 mol% of  $\text{EtMgBr}$  (2.5 M in  $\text{Et}_2\text{O}$ ) in dichloromethane (Scheme 4).

We also succeeded to perform the carbocyclization of  $N^1, N^{10}$ -diallyl- $N^1, N^{10}$ -bis(4-methylbenzyl)deca-2,8-diyne-1,10-diamine **8**, prepared from 1,7-octadiyne, to give bis-methylenepyrrolidine derivative **9** (1,6-bis(4-methyl-1-(4-methylbenzyl)pyrrolidin-3-ylidene)hexane) (Scheme 5).

This study indicates that Ti–Mg-catalyzed carbocyclization of nitrogen-containing enynes with  $\text{Et}_2\text{Zn}$  is equally efficient both for enynes with alkyl substituent at the triple bond (e.g., **3d** and **9**) and enynes with aryl and trimethylsilyl substituents at the triple bond (e.g., **3a–c**, **3e–g**, **3i**, **4h,f**, **5a,h**). For example, it is known that cyclization of unfunctionalized enynes in the course of the  $\text{Cp}_2\text{ZrCl}_2$ -catalyzed cycloaluminumation occurs selectively if directing groups such as phenyl or trimethylsilyl group are present at the triple bond.<sup>48</sup> Perhaps, the agostic interaction between the *ortho*-hydrogen atom of the phenyl group,<sup>49</sup> or the trimethylsilyl group, and the zirconium atom may be a favorable factor promoting the cyclization of enynes in the course of cycloaluminumation. From this standpoint, it was of interest to study the Ti–Mg-catalyzed reaction of  $\text{Et}_2\text{Zn}$  with nitrogen-containing 1,6-enynes containing additional heterofunctional substituents at the triple bond. Carbocyclization of enynes with a bifunctionally substituted triple bond may serve, in the future, for the development of one-pot syntheses of polyfunctionalized pyrrolidine derivatives. Additionally, study of the behavior of these enyne substrates towards carbocyclization would shed light on the electronic and steric effects of substituents at the triple bond in the reaction. We found that the reaction of *N*-allyl-substituted but-2-yn-1,4-diamines **10** with 2.5 equivalents of  $\text{Et}_2\text{Zn}$  in the presence of 15 mol% of  $\text{Ti}(\text{O-}i\text{Pr})_4$ , (0.5 M in hexane) and 20 mol% of  $\text{EtMgBr}$  (2.5 M in  $\text{Et}_2\text{O}$ ) in

**Scheme 7** Putative mechanism of Ti–Mg-catalyzed reaction of allyl substituted but-2-yn-1,4-diamines with  $\text{Et}_2\text{Zn}$ .

dichloromethane results in the regio and stereoselective formation of carbocyclization products **11** and **12** in high yields (Scheme 6). Thus, the presence of the second aminomethyl group at the triple bond in the nitrogen-containing enyne molecules **10** does not prevent the intramolecular cyclization.

The reaction of acetylenic ether **13** with 2.5 equivalents of  $\text{Et}_2\text{Zn}$  in the presence of 15 mol% of  $\text{Ti}(\text{O-}i\text{Pr})_4$ , (0.5 M in hexane) and 20 mol% of  $\text{EtMgBr}$  (2.5 M in  $\text{Et}_2\text{O}$ ) in dichloromethane results in regio and stereoselective formation of methoxy-substituted pyrrolidine derivative **14** (Scheme 6). It is worth noting that, unlike *N,N*-dialkyl substituted 2-alkynylamines, substituted acetylenic alcohols and their ethers are unreactive towards Ti–Mg-catalyzed 2-zincoethylzincation.<sup>28,29</sup>

According to the reaction scheme that we proposed (Scheme 7), ligand exchange between  $\text{Ti}(\text{O-}i\text{Pr})_4$  and  $\text{EtMgBr}$  gives  $(\text{O-}i\text{Pr})_2\text{TiEt}_2$ , which is converted to titanium(II)–ethylene complex (titanacyclopropane intermediate). The displacement of ethylene from the titanium coordination sphere by a enyne molecule affords intermediate **A**. The subsequent coupling of the acetylene and ethylene moieties of the enyne molecule gives titanacyclopentene intermediate **B**, which undergoes transmetalation with  $\text{Et}_2\text{Zn}$  to be converted to organozinc intermediate **C**. The deuterolysis (or hydrolysis) of the latter furnishes the pyrrolidine derivative.

## Conclusions

We report a regio and stereoselective  $\text{Ti}(\text{O-}i\text{Pr})_4$  and  $\text{EtMgBr}$ -catalyzed carbocyclization of allyl propargyl amines with  $\text{Et}_2\text{Zn}$ . It was demonstrated that the presence of amine and ether groups at the enyne triple bond does not prevent

carbocyclization of allyl-substituted 2-alkynylamines. The study resulted in the development of an efficient method for the synthesis of a variety of heteroatom-containing pyrrolidine derivatives *via* organozinc synthesis. The observed tolerance of the Ti-Mg-catalyzed carbocyclization of enynes to the presence of various heterofunctional substituents opens prospects for further use of organozinc synthesis to develop one-pot syntheses of polyfunctional pyrrolidine derivatives. In connection with the obtained carbocyclization reaction we plan to develop an effective method for preparing methylenepiperidine derivatives based on Ti-Mg-catalyzed carbocyclization of *N*-homoallyl substituted 2-alkynylamines.

## Experimental section

### General information

The reagents were obtained from Sigma-Aldrich or Acros. Hexane and dichloromethane were distilled over P<sub>2</sub>O<sub>5</sub>. Diethyl ether, tetrahydrofuran, 1,4-dioxane, toluene, benzene and anisole were dried over sodium. Dried 1,2-dimethoxyethane was obtained from Sigma-Aldrich. 2-Alkynylamines **1a–i** and **6**, **8** were prepared by aminomethylation of terminal alkynes with aqueous formaldehyde and secondary *N*-aryl-substituted allyl amines under CuBr catalysis.<sup>50</sup> Nitrogen-containing 1,6-enynes with terminal propargyl and allyl groups were prepared by alkylation of *N*-aryl-substituted allyl amines with propargyl bromide under NaH.<sup>51</sup> Allyl substituted but-2-yne-1,4-diamines **10** were prepared by aminomethylation of nitrogen-containing 1,6-enynes (with terminal propargyl and allyl groups) by bis-amine.<sup>52</sup> Acetylenic ethers **13** were prepared by aminomethylation of ethers of acetylenic alcohols with aqueous formaldehyde and secondary *N*-aryl-substituted allyl amines

under CuBr catalysis.<sup>50</sup> Nuclear magnetic resonance spectroscopy was performed on a Bruker Avance 500. The <sup>1</sup>H NMR spectra were recorded at 500 MHz and <sup>13</sup>C-<sup>1</sup>H NMR spectra at 100 MHz in CDCl<sub>3</sub>. The chemical shifts are reported in ppm relative to tetramethylsilane (TMS) as the internal standard. The numbering of atoms in the <sup>13</sup>C-<sup>1</sup>H and <sup>1</sup>H NMR spectra of the compounds **3a–g**, **3i**, **4h,f**, **5a**, **5h**, **7**, **9**, **11a–c**, **12a**, **14** is shown in Fig. 1–3. Elemental analysis was performed using a Carlo-Erba CHN 1106 elemental analyser. Mass spectra were obtained on a Finnigan 4021 instrument. The yields were calculated from the isolated amount of pyrrolidine and pyrrolidone derivatives obtained from starting nitrogen-containing 1,6-enynes.

### Preparation of 3-methyl-4-methylenepyrrolidines **3a–g**, **3i**, **4h,f** and **5a,h** *via* Ti-Mg-catalyzed carbocyclization of *N*-allyl substituted propargylamines with Et<sub>2</sub>Zn in CH<sub>2</sub>Cl<sub>2</sub>

**(Z)-1-(4-Methoxybenzyl)-3-methyl-4-((trimethylsilyl)methylene)pyrrolidine; typical procedure.** To a solution of *N*-(4-methoxybenzyl)-*N*-(3-(trimethylsilyl)prop-2-yn-1-yl)prop-2-en-1-amine (574 mg, 2 mmol) and Et<sub>2</sub>Zn (1 M in hexanes, 5 mL, 5 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (6 mL) was added Ti(*i*-Pr)<sub>4</sub> (0.5 M in hexanes, 0.6 mL, 0.3 mmol). Ethylmagnesium bromide (2.5 M in Et<sub>2</sub>O, 0.16 mL, 0.4 mmol) was then added and the reaction mixture rapidly turned black. After 18 h at 23 °C, the reaction mixture was diluted with Et<sub>2</sub>O (5 mL), and 25 wt% KOH solution (3 mL) was added dropwise while the reaction flask was cooled in an ice bath. The aqueous layer was extracted with diethyl ether (3 × 5 mL). The combined organic layers were washed with brine (10 mL), dried over anhydrous CaCl<sub>2</sub>. The reaction mixture was filtered through a filter paper and concentrated *in vacuo* to give crude product as a yellow oil. Evaporation of solvent and purification of the residue by column chromatography (diethyl ether : isopropyl alcohol : hexane = 1 : 1 : 8) gave **3a** (509 mg, 88%) as colorless oil. *R*<sub>f</sub> 0.70.
