Tunable nanostructured distributed Bragg reflectors for III-nitride optoelectronic applications

Bin Wei,^{†ab} Yingkuan Han,^{†b} Yanhao Wang,^a Haonan Zhao,^b Bowen Sun,^b Xiaokun Yang,^b Lin Han,^{id a} Mingming Wang,^c Zhiyong Li,^d Hongdi Xiao^{id b} and Yu Zhang^{*a}

Highly reflective and conductive distributed Bragg reflectors (DBRs) are the key for high-performance III-nitride optoelectronic devices, such as vertical cavity surface emitting lasers (VCSELs), but they still suffer from lack of lattice-matched conductive DBR and uncontrollable processes. In this work, nanostructured GaN-based DBRs were fabricated and optimized both experimentally and simulatively using electrochemical etching (EC) in different electrolytes using the transfer-matrix method (TMM) to obtain uniform wafer scale, highly reflective and conductive reflectors for the application of GaN-based optoelectronics. The results revealed that a nanostructured GaN-based DBR with high reflectivity (>93%) and broad stopband (~80 nm) could be achieved in neutral sodium nitrate by EC, and the nanostructured GaN DBR with a full visible spectrum range could be designed by tuning the thickness of the nanostructured GaN DBR layers. The photoluminescence (PL) and light-out power enhancements of the GaN-based micro-LED by incorporating the fabricated nanostructured GaN-based DBR were 6 times and 150% without the degradation of electrical performance, respectively, which contributed to strong light scattering from the DBR layers. We believe that this work will pave a way to obtain high-performance GaN-based optoelectronic devices and guide the applications in the field of flexible devices and biomedical sensors.

1. Introduction

III-nitrides have been developed over twenty years for high-performance light emitting diodes (LEDs),¹ laser diodes (LDs),² and high-power and high-frequency power electronics³ since the first LED was reported.⁴ Nowadays, LEDs are indispensable in our life; GaN power electronics are on the way to practical applications in the fields of 5G (ref. 5) and fast portable chargers.⁶ However, GaN-based VCSEL, as an important optoelectronic device for use in the fields of displays, laser printing, and high-density optical storage, is still under development and needs further research.⁷ The main challenge is the absence of a suitable DBR with low strain, good conductivity, and high reflectivity for III-nitride materials. Several GaN-based DBRs have been developed, for instance, AlGaIn/GaN,⁸ AlInN/GaN,⁹ and air/GaN¹⁰ or air/AlN.¹¹ However, they suffer from either a difficult growth/fabrication process or non-conductivity.

Therefore, it is still necessary to develop a strain-free, conductive nitride-based DBR.

Recently, a simple technique was developed to produce single-crystal and conductive nano-porous structured GaN by using EC¹² or photo-assisted electrochemical etching (PEC) processing.¹³ By comparison, good EC etching selectivity could be achieved by tuning the applied bias and material conductivity during the EC process,¹² which provided flexibility of the design and application of the GaN nano-porous structure. Multiple applications have been demonstrated by using nano-porous structured GaN produced by the EC process, including epi-lift-off,¹⁴ chemical lift-off,¹⁵ hydrogen generation,¹⁶ gas sensors,¹⁷ biomedical applications,¹⁸ high-performance DBRs,¹⁹ LEDs,²⁰ and laser devices.²¹ There are several advantages of high quality GaN-based DBR fabrication by using the EC technique: (i) perfect lattice match between GaN and the nanostructured GaN strain, resulting in almost strain-free GaN/nanostructured GaN heterostructures, (ii) reflective index (n) tunable from $n = 2.5$ to $n = 1$ by either GaN doping or applied EC bias, (iii) good conductivity of Si-doped GaN, and (iv) the orientation independent isotropic etching of GaN materials. By taking these advantages, (Al)GaN nanostructured DBRs have been obtained by using Si-doped (Al)GaN and unconventionally doped (UID) (Al)GaN alternative stacks,^{22–24} and incorporated into GaN-based optoelectronics, including blue LEDs²¹ and UV LEDs.²⁵

However, the study of GaN/GaN nanostructured DBRs by using all Si-doped GaN layers is still lacking.

Besides, the EC process involves many parameters, such as electrolyte chemistry, applied bias, doping concentration of the semiconductor, and surface conditions, which making it very complex and difficult to control. In the literature, different parameters affecting the EC process and GaN nanostructure performance were reported, and different results were obtained. For instance, oxalic acid was used to produce nano-porous GaN with different Si-doping concentrations, and microdisk and cantilever devices were demonstrated;¹² ethanol/glycerol buffered HF was used to etch Si-doped GaN by the EC process and highly reflective air/GaN DBR (>98%) was achieved with four pairs of GaN/air stack;²⁶ HNO₃ and H₂SO₄ electrolytes were studied and highly reflective GaN/nanoporous DBR was obtained in HNO₃ by using a Si-doped GaN/UID GaN stack;²⁷ KOH and different 1-ethyl-3-methylimidazolium-based ionic liquid electrolytes were also used to produce porous GaN under UV illumination.^{13,28} Among these studies, many electrolytes are highly toxic and/or corrosive, which make the (P)EC process challenging and dangerous from the technical and safety point of view. Therefore, the EC process using neutral or non-aggressive electrolytes needs to be developed/studied together with the control of each parameter for the GaN nanostructure.

In this work, the selective etching of the n^+ -Ga_{0.99}N_{0.01}/Si/ n^- -Ga_{0.99}N_{0.01}/Si alternative layers was studied by EC in different environment friendly electrolytes for optoelectronic application. The effects of the neutral electrolyte and applied bias were investigated in terms of the etching nanostructure morphology and the reflectivity of nanostructured GaN. The tunability of the nanostructured-GaN DBR was explored through transfer-matrix method (TMM) simulation by varying thickness and stack pairs of the nanostructured GaN layer. Finally, we demonstrated that the performance improved the micro-LED by using the developed nanostructured GaN DBR.

2. Materials and methods

GaN and GaN LED structures with GaN nanostructured DBR were grown on a 2-inch patterned sapphire substrate using a metal-organic chemical vapor deposition (MOCVD) system.

The epitaxial structure consisted of a 20 nm-thick sputtered AlN and 2 μ m-thick unintentionally doped (UID) GaN buffer layer, a 1 μ m-thick heavily doped GaN layer ($1 \times 10^{19} \text{ cm}^{-3}$) to improve the etching uniformity of the porous GaN DBR, and a stack structure of 15 pairs of n^+ -Ga_{0.99}N_{0.01}/Si/ n^- -Ga_{0.99}N_{0.01}/Si epitaxial layers (46 nm/ $1 \times 10^{19} \text{ cm}^{-3}$, 60 nm/ $2 \times 10^{18} \text{ cm}^{-3}$), as shown in Fig. 1(a). 46 nm/60 nm was designed to form a stopband centered at about 450 nm. For the LED structure, as shown in Fig. 1(b), a 50 nm thin UID GaN cap layer was grown on the structure shown in Fig. 1(a), followed by an n -AlGa_{0.3}N electron blocking layer, an InGa_{0.3}N/GaN (well/barrier) multilayer, and heavily Mg-doped P-GaN layer. An *in situ* annealing process was used to activate the p-doping of the LED structure with nitrogen flow in the MOCVD reactor.

Electrochemical etching was carried out in the setup shown in Fig. 1(c). The GaN sample and platinum wire were used as the anode and cathode, respectively. Computer controlled power meter was used to supply power and record the process current and voltage. 0.3 M oxalic acid and 0.3 M sodium nitrate were chosen as the electrolytes for studying the electrolyte-dependent doped GaN etching selectivity because they are both environment friendly. The samples were rinsed in deionized water and blow dried by using a nitrogen gun after EC processing. Ideally, n^+ -Ga_{0.99}N_{0.01} ($1 \times 10^{19} \text{ cm}^{-3}$) was transferred into high-porosity nanostructured GaN as a low refractive index layer and n^- -Ga_{0.99}N_{0.01} ($2 \times 10^{18} \text{ cm}^{-3}$) was kept unetched or transferred into the low-porosity nanostructured GaN as the high refractive index layer during electrochemical etching. A highly reflective conductive nanostructured GaN based DBR was formed.

The LED wafer was processed to obtain rectangular LEDs of dimensions $100 \times 80 \mu\text{m}^2$. The fabrication process was as follows: GaN was patterned by chlorine-based inductively coupled plasma reactive ion etching process to reach the N-type region. GaN nanostructured DBR was formed by using electrochemical etching in 0.3 M sodium nitrate. P- and N-contacts were then patterned and deposited to obtain independently addressable LEDs. After that, a silicon dioxide (SiO₂) passivation layer was deposited and a lithographic step opened the P- and N-contact pads.

The top and cross-sectional micrographs of the samples were observed using a field-emission scanning electron microscope

Fig. 1 Schematic structures of the DBR (a) and LED (b) samples; (c) diagram of the electrochemical etching setup.

(SEM). The reflectance spectra and photoluminescence (PL) spectra were measured by using an Ideaoptics PG4000 spectrum system with a halogen light source and a 405 nm laser, respectively. The transfer-matrix method (TMM) was used to simulate the reflectivity of the nanostructured GaN DBR. The characterization of the LEDs was conducted on a semi-auto optoelectronic probe station with a 2 inch integrating sphere and a Keithley 2600 source meter.

3. Results and discussion

3.1 Morphology and reflectivity

Fig. 2 shows the top view (a) and (b) and cross-sectional (c) and (d) view SEM images and the corresponding reflectivity spectra (e) and (f) of GaN nanostructured DBR produced by electrochemical etching in 0.3 M oxalic acid electrolyte at different biases of 12 V (a, c and e) and 18 V (b, d and f), respectively. From the top SEM images of nanostructured GaN DBR, as shown in Fig. 2(a) and (b), we can see some nanoscale pores formed on the sample surface, whose the pore size is about 20–30 nm in diameter and increases with an increase in the applied bias; the pore density increases from $4.3 \times 10^8 \text{ cm}^{-2}$ to $7.6 \times 10^8 \text{ cm}^{-2}$ with an increase in the applied bias, which is comparable with the GaN defect density ($\sim 1 \times 10^8$ to $1 \times 10^9 \text{ cm}^{-2}$) grown on a sapphire substrate. These initial nanopore formations may be dislocation related EC etching.²⁹ From the cross-sectional view SEM images of the samples, as shown in Fig. 2(c) and (d), random pores were formed throughout the whole n^+ -GaN/ n^- -GaN alternative multilayer and there is no clear interface observed for both low and high applied bias conditions. The pore size and porosity of the samples increase with an increase in the applied bias. As shown in the inset of

Fig. 2(c), the nanoscale pores formed on the surface went through the top n^- -GaN extending to the underlying n^+ -GaN layer and enabled the underlying etched layers to form random nanostructures. The reflectance spectra of the samples are shown in Fig. 2(e) and (f) and the measured reflectivity of the samples was only 63.03% and 39.31% for low (12 V) and high (18 V) applied bias conditions, respectively. This implying that the samples had a bad optical performance and oxalic acid electrolyte is not suitable for making high quality nanostructured GaN-based DBRs.

By comparison, Fig. 3 shows the top view (a) and (b) and cross-sectional (c) and (d) view SEM images and the corresponding reflectance spectra (e) and (f) of nanostructured GaN-based DBR produced by electrochemical etching in 0.3 M NaNO_3 electrolyte at different biases of 12 V (a, c and e) and 18 V (b, d and f), respectively. From the top view SEM images of nanostructured GaN DBR, as shown in Fig. 3(a) and (b), we can see some much smaller nanoscale pores formed on the sample surface, whose pore size is about 10–20 nm in diameter and almost remains constant with an increase in the applied bias; the pore density also increases from $4.3 \times 10^8 \text{ cm}^{-2}$ to $7.2 \times 10^8 \text{ cm}^{-2}$ with an increase in the applied bias. The pore size and porosity of porous GaN are the functions of applied etching bias and Si-doping concentration of the GaN layer, and increase on increasing either/both GaN layer doping concentration or/and applied etching bias.^{18,19} The pore size of porous GaN is in the range of 10–100 nm regardless of the GaN layer doping concentration and the applied etching bias. Therefore, we believe that there are no pores with diameter less than 10 nm formed in the n -GaN layers. The porosity of the formed porous GaN is low for low Si-doping GaN layer and high for high Si-doping GaN layer at fixed applied etching bias in the porous

Fig. 2 Top view (a) and (b) and cross-sectional (c) and (d) view SEM images and the corresponding reflectance spectra (e) and (f) of GaN nanostructured DBR produced by electrochemical etching in 0.3 M oxalic acid electrolyte at different biases of 12 V (a, c and e) and 18 V (b, d and f), respectively.

Fig. 3 Top view (a) and (b) and cross-sectional (c) and (d) view SEM images and the corresponding reflectance spectra (e) and (f) of GaN nanostructured DBR produced by electrochemical etching in 0.3 M NaNO_3 electrolyte at different biases of 12 V (a, c and e) and 18 V (b, d and f), respectively.

etching regime of the phase diagram for GaN EC etching.¹⁸ From the cross-sectional view SEM images of the samples, as shown in Fig. 3(c) and (d), triangular and elongated pores were formed in the n^+ -GaN layers; only a few nanopores were observed in the n^- -GaN layer. The small pores and defects in n^- -GaN layers would be the vertical porosification routes for the bottom n^+ -GaN layers.²⁴ A clear interface between the n^+ -GaN layer and the n^- -GaN layer was observed for both low and high applied bias conditions, indicating that good selectivity between the n^+ -GaN and n^- -GaN layers can be achieved in NaNO_3 electrolyte. The ratio of the elongated pores to the triangular pores of the samples increases with an increase in the applied bias because lateral etching was enhanced in the highly conductive n^+ -GaN layer. The measured and simulated reflectance spectra of the samples are shown in Fig. 3(e) and (f), and

the measured reflectivity of the samples was 74.44% at 12 V and 86.39% at 18 V, respectively. The stopband width of the samples was 47 nm at 12 V and 67 nm at 18 V. The peak reflectivity wavelength of the samples shifted to shorter wavelength from 490 nm to 473 nm because of the increase in porosity of the nanostructured n^+ -GaN layer. The refractive index of the nanostructured GaN layer changed from 1.953 at 12 V to 1.926 at 18 V, which was obtained through the TMM simulation by taking 2.5 as the n^- -GaN refractive index. As we can see, a higher applied bias resulted in a smaller refractive index of the nanostructured GaN, leading to a smaller optical thickness of the nanostructured GaN, which made the blue-shifted the central reflective wavelength. All the results imply that the samples had a better optical performance and NaNO_3 electrolyte is a good

electrolyte for making nanostructured GaN-based DBRs by electrochemical etching.

To answer the question as to why the performance of nanostructured GaN-based DBR produced by using 0.3 M NaNO₃ electrolyte is better than that produced by using 0.3 M oxalic acid electrolyte, the principal mechanism of porous GaN by EC process must be considered. It has been reported³⁰ that porous GaN formation involves several stages during the EC process: (i) hole generation in GaN near the inside surface, (ii) GaN surface specific spot oxidation through hole transfer and recombination, and (iii) eventual dissolution of the oxidation complex in the electrolyte. The whole process includes potential distribution, ion drifting, mass transfer, and electrolyte flow and is very complex, which involves multifield dynamic theories in physics, chemistry, and nanofluidics.³¹ In our experiments, the GaN carrier concentration, applied bias, and electrolyte play a key role in the process. On comparing the EC conditions, the only difference is the ions in the electrolyte, which are Na⁺ and NO₃⁻ in NaNO₃ and (C₂O₄)²⁻ and H⁺ in oxalic acid. The most accepted reaction mechanism that the applied bias drove the generated holes in GaN to the surface resulted in the oxidation of the GaN surface has been proposed. Meanwhile, Ga³⁺ ions and N₂ gas were generated near the GaN surface; thus, the nanostructured nanoporous GaN could be achieved.³² Based on some reports,^{13,33} the process can be expressed as:

For eqn (1) and (2), both Ga₂(C₂O₄)₃ and Ga(NO₃)₃ are water soluble and easy to dissolve in the aqueous electrolyte. From the above analysis, we can predict that the different properties of nanostructured GaN-based DBR are attributed to different anions in the electrolytes because the only difference is the ions in the electrolyte in the whole process, as mentioned above. It may be due to (C₂O₄)²⁻ being larger than NO₃⁻ in volume and more difficult to sink to the bottom of the pores during the process, leading to the random nanostructured porous GaN in Fig. 2(c) and (d). On the other hand, NO₃⁻ can go through the nanoscale channel easily and reach the bottom of the pore to continue the etching of the pores. Therefore, a uniform nanostructured GaN layer can be formed in NaNO₃ electrolyte. We could estimate that (i) the performance of the nanostructured GaN-based DBR could be improved by tuning the EC etching condition and the thickness of the nanostructured GaN-based DBR alternative layer (*n*⁺-GaN and *n*⁻-GaN layer thickness); (ii) the other salt trinitrate, such as KNO₃,³³ also can be used as an electrolyte to produce uniform nanostructured GaN-based DBR.

The uniformity of DBR is an important property for real applications. To verify the uniformity of the nanostructured GaN-based DBR, we performed 2 inch wafer scale nanostructured GaN-based DBR in 0.3 M NaNO₃ by EC at 18 V. Fig. 4(a) shows a photograph of the wafer-scale nanostructured GaN-based DBR under room-light illumination and the reflection of a business card with a Shandong University logo. The clear reflective images of the Shandong University logo were observed in the DBR region, indicating the high reflectivity of DBR. However, the unetched region is transparent and there is no observation of a reflective image of the Shandong University logo in the unetched region. The high reflection in the DBR region demonstrates the uniformity of the EC process. In order to further confirm the uniformity of the DBR, the reflectivity of the sample shown in Fig. 4(a) was measured on 5 labelled spots over the whole wafer and the unetched region (GaN sample before etching), as shown in Fig. 4(b). The detailed uniformity analysis is listed in Table 1. As can be seen, the reflectivity of the unetched region is ~20%. On the other hand, the average reflectivity of DBR is about 83% with a small variation of 1.6%, which is consistent with the results shown in Fig. 3. The

**Fig. 5** Top view (a) and cross-sectional view (b) SEM images and the experimental and simulated reflectance spectra (c) of GaN nanostructured DBR produced by EC etching in 0.3 M NaNO₃ electrolyte at 22 V.

stopband width of the DBR is up to 80 nm with a negligible average variation of 0.02 nm over the 2 inch wafer scale. These results strongly confirmed the highly uniform DBR and the stable fabrication process.

3.2 Performance tuning of the nanostructured GaN-based DBR

Based on the comparison of the results for nanostructured GaN DBR fabricated in different electrolytes, the better results of nanostructured GaN DBR can be obtained by using 0.3 M NaNO_3 electrolyte in the electrochemical etching process. The nanostructured GaN-based DBR process was further optimized in 0.3 M NaNO_3 electrolyte by tuning the EC applied bias to higher voltage (22 V) to achieve a uniform GaN nanostructure and high reflectivity of the nanostructured GaN DBR. The results are shown in Fig. 5. Fig. 5(a) shows the top view SEM image of the DBR and a similar morphology of the DBR was observed with Fig. 3(a) and (b), which has some nanoscale pores on the surface that serve as the etching starting points. Fig. 5(b) shows the cross-sectional SEM image of the DBR. A uniform

porous GaN layer and a GaN layer alternative stack was formed, resulting in the high reflectivity of the nanostructured GaN-based DBR, as shown in Fig. 5(c). The reflectivity and stopband width of the DBR were measured to be 93.7% and 80 nm with the central wavelength of about 467 nm, respectively. The simulated reflectivity, central wavelength, and stopband width were matched with the measured results by taking 1.844 as the refractive index of the porous GaN layer.

Simulation is a powerful tool to study the properties of the DBR within a short time and low cost. By taking the advantages of the simulation, the properties of the nanostructured GaN-based DBR were analyzed by varying the thickness of the DBR alternative layer with other parameters fixed using Essential Macleod package based on the experimental results. The basic parameters of the DBR used in the simulation are listed in the Table 2. It is important to note that the refractive index of bulk GaN ($n = 2.5$) is used for alternate n^- -GaN layers in the simulation, assuming that the small pores in these layers would not influence its properties. We fixed all the parameters of the nanostructured GaN-based DBR except the alternative layer thickness to study its performance. Fig. 6(a) shows the

Table 2 The basic parameters of the GaN nanostructured DBR used for simulation

	Al_2O_3 substrate	GaN buffer layer	n^+ -GaN layer (nanostructured layer)	n^- -GaN layer
Thickness (nm)	—	3000	37	67
Refractive index (n)	1.67	2.5	1.844	2.5
Doping concentration ($1 \times 10^{18} \text{ cm}^{-3}$)	—	—	10	2

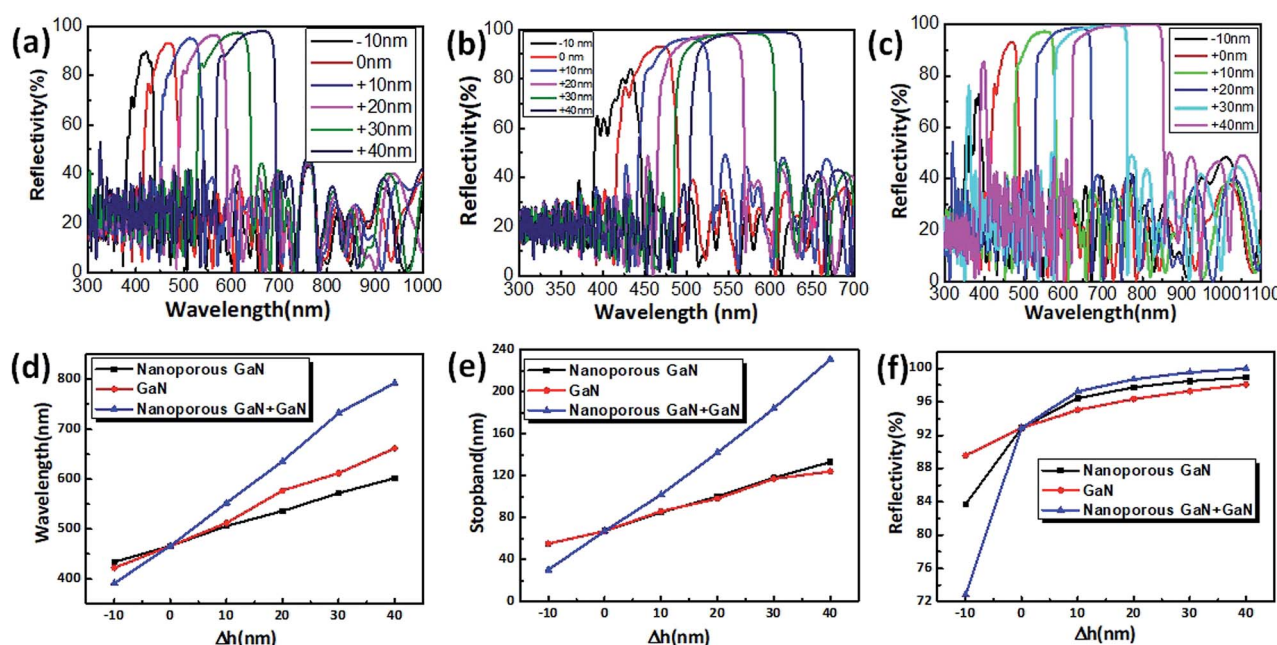

Fig. 6 Simulated reflectance spectra of nanostructured GaN-based DBR by tuning the (a) GaN layer thickness, (b) porous GaN layer thickness, and (c) both of the GaN and porous GaN layer thickness. (d) Central wavelength, (e) stopband width, and (f) reflectivity of the nanostructured GaN-based DBR as a function of the thickness of DBR alternative layers.

Fig. 7 Simulation reflectivity spectra of the nanostructured GaN-based DBR with different pairs.

reflectivity of the DBR with different n^- -GaN layer thickness in the range from 57 nm to 107 nm based on the fabricated DBR n^- -GaN layer thickness listed in Table 2. Fig. 6(b) shows the reflectivity of the DBR with different nanostructured GaN layer thickness in the range from 27 nm to 77 nm based on the fabricated DBR n^+ -GaN layer thickness listed in Table 2. Fig. 6(c) shows the reflectivity of the DBR with tuning of the nanostructured GaN layer from 27 nm to 77 nm and the n^- -GaN layer thickness from 57 nm to 107 nm. It can be seen that: (i) the peak reflective wavelength of the DBR shifted to longer wavelength from near UV to near IR with an increase in the thickness of the

DBR alternative layers because of $n_1 t_1 = n_2 t_2 = \lambda/4$; the thicker alternative layer resulted in longer peak wavelength, as shown in Fig. 6(d). (ii) The stopband width of the DBR became wider with an increase in the thickness of the alternative layer, which could be due to the more uniform porous nanostructure formed in the DBR. Up to 200 nm stopband width can be achieved by increasing the period layer thickness (as shown in Fig. 6(e)). (iii) The reflectivity of the DBR also increased gradually and reached near 100% on increasing the period layer thickness, as shown in Fig. 6(f).

The pair number of the DBR is another key parameter influencing the real applications. Fig. 7 shows the simulated reflective spectra of the nanostructured GaN-based DBR with a variation in the alternative layer pairs from 10 to 25. It can be seen that the reflectivity of the DBR does not always increase with the increase in the number of alternating layer pairs in the nanostructured GaN-based DBR. Only a little improvement in the reflectivity is observed on increasing the DBR pairs from 15 to 20 and almost the same reflectivity value is obtained on increasing the DBR pairs from 20 to 25. But the reflectivity of the DBR drops quickly when the DBR pairs reduce from 15 to 10. This could be due to the fact that there will be more scattering effect at the roughening interfaces in the porous layers of the DBR nanostructure.³⁴ The results implied that there is a minimum alternative period pair for maximum reflectivity of the nanostructured GaN-based DBR with certain alternative layer thickness. The reflectivity of the nanostructured GaN-based DBR would not increase on increasing the alternative pair after the DBR reached certain pairs. We have to tune the

Fig. 8 (a) Real lit-up blue LED with GaN nanostructured DBR on a 2 inch wafer, (b) the cross-sectional SEM image of the LED, (c) PL spectra and (d) L-I-V of LED with (blue line) and without (black line) nanostructured GaN-based DBR (inset: optical images of the LED).

other parameter, for instance, the alternative layer thickness and the applied bias, to reach higher reflectivity (near 100%). It should be noted that nearly 100% reflectivity of the nanostructured GaN-based DBR with 15 period pairs could be achieved by tuning the period thickness and the applied bias, which provided the DBR design and application flexibility.

3.3 Nanostructured GaN DBR for optoelectronic device application

To demonstrate the optoelectronic applications, the GaN-based LEDs with nanostructured GaN-based DBR were fabricated and characterized. Fig. 8(a) shows the wafer-level real lit-up blue LED with nanostructured GaN-based DBR on the testing probe station and the inset shows the optical microscope images of the processed micro-LED. Fig. 8(b) shows the cross-sectional SEM image of the LED sample with nanostructured GaN-based DBR. The clear nanostructured GaN-based DBR is formed under InGaN/GaN MQWs after the EC process in 0.3 M NaNO₃ electrolyte at 18 V without any degradation of the InGaN/GaN MQWs active layer. The room-temperature PL curves of the LEDs without and with nanostructured GaN-based DBR produced in 0.3 M NaNO₃ electrolyte at 18 V were obtained to explore the influence of the DBR layer on the LED optical properties, as shown in Fig. 8(c). All the LED samples emit at a wavelength of about 460 nm. A 6 times enhanced PL peak intensity can be observed for the LED with nanostructured GaN-based DBR. This is because the formed nanostructured GaN-based DBR can effectively increase light scattering, resulting in better light extraction.³⁵ The L-I-V characteristics of unpackaged LEDs from the LEDs with and without nanostructured GaN-based DBR are shown in Fig. 8(d) and the inset shows the optical microscope image of the lit-up LED with nanostructured GaN-based DBR. Under a driving current of 20 mA, the forward voltages of the LEDs with and without nanostructured GaN-based DBR were 3.5 V and 3.4 V, respectively. The output power of the LEDs with and without nanostructured GaN-based DBR was measured to be 4.7 mW and 3.1 mW, respectively. The light output power improvement of about 150% was obtained. Therefore, it can be concluded that the LED performance is enhanced as the light extraction is improved by the nanostructured GaN-based DBR layer.

4. Conclusions

In summary, the nanostructured GaN-based DBR was fabricated by using all Si-doped GaN layers and was optimized both experimentally and simulatively using electrochemical etching in different electrolytes and TMM method. High performance nanostructured GaN based DBR with high reflectivity (>93%) and broad stopband (~80 nm) was achieved in neutral sodium nitrate by EC, and nanostructured GaN DBR with nearly 100% reflectivity and full visible spectrum range can be designed by tuning the thickness of the alternative layers of nanostructured GaN DBR. The photoluminescence (PL) and light-out power enhancements of the GaN-based micro-LED are 6 times and 150% without the degradation of electrical performance,

respectively, which was achieved by the incorporation of the fabricated nanostructured GaN-based DBR in the micro-LED that contributes to the strong light scattering from the DBR layer. We believe that this work will pave a way to high performance GaN-based optoelectronics devices and guide the applications in the field of flexible devices and biomedical sensors.
