## Catalytic oxidation of NO over $\text{MnO}_x\text{--CoO}_x\text{/TiO}_2$ in the presence of a low ratio of $\text{O}_3\text{/NO}$ : activity and mechanism†

 Meng Si,  <sup>a</sup> Boxiong Shen, <sup>\*a</sup> Lijun Liu, <sup>a</sup> Haohao Zhang, <sup>a</sup> Wenjun Zhou, <sup>a</sup> Jianqiao Wang, <sup>a</sup> Xiao Zhang, <sup>a</sup> Zhikun Zhang <sup>a</sup> and Chunfei Wu <sup>b</sup>

In order to broaden the temperature range of NO oxidation reaction in flue gas and maintain high oxidation efficiency, various loading amounts of  $\text{MnO}_x\text{--CoO}_x\text{/TiO}_2$  mesoporous catalysts were tested in the catalytic oxidation of NO. It was found that 15% $\text{MnO}_x\text{--CoO}_x(2:1)\text{/TiO}_2$  demonstrated the best adsorption performance to oxygen species and contained more oxygen vacancies, as well as the best surface oxygen mobility, thus exhibiting excellent NO catalytic oxidation activity.  $\text{O}_3$  ( $\text{O}_3\text{/NO} < 1$ ) combined with 15% $\text{MnO}_x\text{--CoO}_x(2:1)\text{/TiO}_2$  improved the oxidation efficiency of NO at 50–400 °C, especially below 250 °C. When the temperatures were less than 250 °C, the oxidation efficiencies of NO by  $\text{O}_3$  over 15% $\text{MnO}_x\text{--CoO}_x(2:1)\text{/TiO}_2$  were 5–13% higher than the calculated theoretical efficiencies. This indicated that there was a synergistic effect between  $\text{O}_3$  and 15% $\text{MnO}_x\text{--CoO}_x(2:1)\text{/TiO}_2$  below 250 °C. Based on the results of *in situ* DRIFTS studies, it was deduced that monodentate nitrates were the main intermediates that produced a synergistic effect due to the introduction of  $\text{O}_3$ . In addition,  $\text{O}_3$  accelerated the transformation between nitrate species, decreased the decomposition temperature of nitrate species, and inhibited the accumulation of nitrate ions, thus improving the oxidation efficiency of NO.

### 1. Introduction

$\text{NO}_x$  (including NO and  $\text{NO}_2$ ) are major pollutants emitted from fossil fuel combustion. In the last two decades, there has been much concern on techniques to control  $\text{NO}_x$  emission. Selective catalytic reduction and selective non-catalytic reduction are widely used in industry,<sup>1</sup> but the problems of high reaction temperature requirement,  $\text{NH}_3$  escape in flue gas, and difficulty in removing low concentrations of  $\text{NO}_x$  still exist.<sup>2–4</sup> In recent years, the oxidation technology of NO to  $\text{NO}_2$  has received attention.<sup>5–8</sup> In particular, the applications of transition metal oxides to catalytic oxidation of NO were studied.<sup>9–12</sup> Among them,  $\text{MnO}_x$  and  $\text{CoO}_x$  have been reported to show good activity for NO catalytic oxidation. Qiu<sup>13</sup> prepared  $\text{Mn}\text{--Co/TiO}_2$  catalysts with different loadings by wet impregnation method. Their results indicated that the efficiency of NO oxidation by  $\text{O}_2$  was the best using 10Mn–5Co/ $\text{TiO}_2$  (loading ratio of Mn was 10 wt%

and Co was 5 wt%) at 300 °C. Li<sup>14</sup> found that the interaction between Co and Mn promoting the generation of  $\text{Mn}_2\text{O}_3$  improved the NO oxidation by  $\text{O}_2$  above 250 °C. Nevertheless, the catalytic oxidation of NO by catalysts combined with oxygen is inefficient when the temperature was below 150 °C. To obtain higher efficiency of NO oxidation at low temperature, ozone has been widely used considering the lower secondary pollutants.<sup>6,15</sup> Jōgi<sup>16</sup> reported the NO oxidation by ozone over  $\text{TiO}_2$  catalyst and Lin<sup>17</sup> reported the NO oxidation by  $\text{O}_3$  combined with  $\text{MnO}_x$  catalyst supported by spherical alumina. It is agreed in these papers that when the temperature was less than 200 °C and the molar ratio of  $\text{O}_3\text{/NO} < 1$ , the catalysts had no promoting effect on NO oxidation by  $\text{O}_3$ , and the oxidation efficiency of NO to  $\text{NO}_2$  was the same as that when ozone oxidized NO alone. When the ratio of  $\text{O}_3\text{/NO}$  was greater than 1, the presence of catalysts could promote the deep oxidation of  $\text{NO}_2$  to  $\text{N}_2\text{O}_5$  by  $\text{O}_3$  and reduce the consumption of ozone. However, higher  $\text{O}_3\text{/NO}_x$  could result in the leakage of ozone and the increase in capital cost. Therefore, NO oxidation by catalysts combined with low concentration of  $\text{O}_3$  has become a new research target. Han<sup>18</sup> found that black- $\text{TiO}_2$  catalyst could increase the removal rate of NO in ozonation system at 60 °C when  $\text{O}_3\text{/NO} = 0.6$ . However, so far, there have been few reports about the NO catalytic oxidation mechanism with low molar ratios of  $\text{O}_3$  to NO.

In this study,  $\text{MnO}_x\text{--CoO}_x\text{/TiO}_2$  catalysts with different loadings were prepared with 2 : 1 molar ratio of Mn to Co. The

performance of these catalysts was investigated in NO catalytic oxidation. The optimum catalyst was selected for the research of NO oxidation by low molar ratios of  $O_3/NO$  ( $O_3/NO < 1$ ) at 50–400 °C. A series of characterization techniques, such as  $N_2$  adsorption, X-ray diffraction (XRD), thermogravimetric-differential scanning calorimetry (TG-DSC),  $H_2$ -temperature program reduction ( $H_2$ -TPR),  $O_2$ -temperature program desorption ( $O_2$ -TPD) and X-ray photoelectron spectroscopy (XPS), were used to identify the physicochemical characteristics of the catalysts. The technology of *in situ* DRIFTS was introduced to explore the promotion mechanism of NO oxidation by low concentration of  $O_3$  in presence of  $MnO_x$ – $CoO_x$ /TiO<sub>2</sub>.

## 2. Materials and methods

### 2.1 Catalyst preparation

The catalysts were prepared by impregnation method. Specific amounts of manganese nitrate solution (50 wt%, analytical grade) and  $Co(NO_3)_2 \cdot 6H_2O$  crystals (99 wt%, analytical grade) were added into 100 mL deionized water and the mixture was stirred for 30 min. A certain amount of anatase TiO<sub>2</sub> powder (commercial anatase titanium dioxide) was added into the solution and stirring was continued for 2 hours. Then, the mixture was heated in a thermostatic water bath at 80 °C until the water was fully evaporated. The catalyst precursors were dried at 110 °C for 12 hours, and then calcined under air atmosphere at 500 °C for 4 hours. The calcined catalysts were ground to 40–60 mesh size for the activity tests. For the as-prepared  $MnO_x$ – $CoO_x$  supported catalysts, the molar ratio of Mn to Co was 2 : 1 and total loadings of Mn and Co to TiO<sub>2</sub> were 7 wt%, 10 wt%, 15 wt% and 20 wt%. Accordingly, they were denoted as 7% $MnO_x$ – $CoO_x$ (2 : 1)/TiO<sub>2</sub>, 10% $MnO_x$ – $CoO_x$ (2 : 1)/TiO<sub>2</sub>, 15% $MnO_x$ – $CoO_x$ (2 : 1)/TiO<sub>2</sub> and 20% $MnO_x$ – $CoO_x$ (2 : 1)/TiO<sub>2</sub>, respectively.

### 2.2 Catalyst characterization

The specific surface areas and pore size distributions were determined by  $N_2$  adsorption at liquid nitrogen temperature 77 K using a Micromeritics ASAP 2020 HD88 instrument. XRD patterns were recorded by a D8 FOCUS X-ray diffractometer (Bruker) with Cu K $\alpha$  radiation operated at 40 kV and 40 mA. TGA curves were recorded on a TA-Q600 analyzer over the temperature range from 20 °C to 1000 °C at the rate of 10 °C min<sup>-1</sup> under  $N_2$ .  $H_2$ -TPR,  $O_2$ -TPD and NO-TPD were carried out on PCA-1200 chemical adsorption instrument with a thermal conductivity detector. For  $H_2$ -TPR, samples were pretreated at 200 °C for 90 min in nitrogen atmosphere, then cooled down to room temperature. Catalysts were flushed in a flow of  $H_2$  (5%)/ $N_2$  and then heated to 900 °C at a rate of 10 °C min<sup>-1</sup>. The  $H_2$  consumption of the test samples were calculated by the  $H_2$  consumption of 50 mg of CuO under the same reaction conditions. For  $O_2$ -TPD, catalysts were purged at room temperature for 30 min and then at 200 °C for 2 h in He atmosphere. Subsequently,  $O_2$  was adsorbed at 100 °C for 1 h. The adsorbed catalyst was blown by He for 30 min at 100 °C, and then raised to 900 °C in He atmosphere (30 mL min<sup>-1</sup>) at a rate of 10 °C min<sup>-1</sup>.

The  $O_2$  desorption quantity of each sample was calculated by standard pulse peak calibration method. For NO-TPD, catalysts were purged at 300 °C for 1 h in He atmosphere and then cooled down to room temperature. Subsequently, NO was adsorbed at room temperature for 1 h. The adsorbed catalysts were blown by He for 1 h at room temperature, and then raised to 500 °C in He atmosphere (30 mL min<sup>-1</sup>) at a rate of 10 °C min<sup>-1</sup> for desorption experiments. Desorption signals were detected by a thermal conductivity detector. XPS data were collected using a ThermoScientific Escalab 250Xi photoelectron spectrometer with a standard Al K $\alpha$  source ( $h\nu = 1486.6$  eV). All binding energies were referenced to the C 1s line at 284.8 eV.

### 2.3 Catalytic tests

Activity tests of catalysts were carried out at 50–400 °C in a fixed-bed reactor that was 0.8 cm in diameter and 20 cm in length; the experimental system is shown in Fig. S1.† The simulated flue gases included 500 ppm NO, 4%  $O_2$  and  $N_2$  as carrier.  $O_3$  was generated from  $O_2$ -ozone generator (SK-CFG-10A, 1–10 g h<sup>-1</sup>, Sankang, Jinan, China), and was monitored by ozone detector (GM-6000-OEM, 0–200 g m<sup>-3</sup>, Anseros, Germany). The molar ratio of  $O_3/NO$  was 0.1 to 0.9. The total gas flow rate was 400 mL min<sup>-1</sup> with a gaseous hourly space velocity (GHSV) of 24 000 h<sup>-1</sup>. The inlet and outlet NO concentrations were determined by flue gas analyzer (KM940, Kane, UK). The conversion efficiency of NO was calculated by eqn (1):

$$\text{NO oxidation efficiency} = \frac{NO_{\text{inlet}} - NO_{\text{outlet}}}{NO_{\text{inlet}}} \times 100\% \quad (1)$$

where  $NO_{\text{inlet}}$  and  $NO_{\text{outlet}}$  denote the inlet and outlet NO concentrations (ppm), respectively.

### 2.4 *In situ* DRIFTS

*In situ* diffuse reflectance infrared Fourier transform spectroscopy (DRIFTS) was performed using a Bruker Tensor II instrument and Harrick Scientific DRIFTS cell with ZnSe windows. The total gas flow rate was 200 mL min<sup>-1</sup> containing 500 ppm NO, 250 ppm  $O_3$ , 4%  $O_2$  and  $N_2$  as carrier. The samples were pretreated under  $N_2$  atmosphere in DRIFTS cell at 400 °C for 1 h, and then cooled down to the target temperature to collect the background spectra. The spectra of  $NO_x$  desorption as a function of temperature (25–400 °C) were recorded. The simultaneous adsorption data of NO and  $O_3$  or NO and  $O_2$  on 15%  $MnO_x$ – $CoO_x$ (2 : 1)/TiO<sub>2</sub> as a function of time were recorded at 100 °C and 350 °C, respectively. Static reaction spectra without fed gases, after NO and  $O_3$  co-adsorbed on 15% $MnO_x$ – $CoO_x$ (2 : 1)/TiO<sub>2</sub> at 100 °C, was also recorded.

## 3. Results and discussion

### 3.1 Catalyst characterization

**3.1.1  $N_2$  adsorption analysis.** The results of  $N_2$  adsorption analysis of  $MnO_x$ – $CoO_x$ (2 : 1)/TiO<sub>2</sub> catalysts with different loading amounts are shown in Fig. 1. The BET surface area, total pore volume and average pore width decreased with the increase in total loading amount (listed in Table 1). It was found

Fig. 1 (a)  $N_2$  adsorption–desorption curves and (b) pore size distribution curves of  $MnO_x$ – $CoO_x$ (2 : 1)/ $TiO_2$ .

that  $N_2$  adsorption and desorption isotherm curves (shown in Fig. 1(a)) were inconsistent at high  $P/P_0$  ( $>0.6$ ). The curves belonged to a typical type IV isotherm, which indicated that these catalysts were all mesoporous materials. The catalysts exhibited a uniform pore size distribution with a mesoporous developed pore structure. The increase in catalyst loading amount resulted in a slight decrease in pore size distribution (shown in Fig. 1(b)).

**3.1.2 TG-DSC analysis.** Fig. 2 shows the results of TG-DSC analysis. All the catalysts showed a significant weight loss at around  $600\text{ }^\circ\text{C}$ . Four decalescence points were observed on 15%  $MnO_x$ – $CoO_x$ (2 : 1)/ $TiO_2$  from the DSC curves, but other catalysts had three. The decalescence points less than  $100\text{ }^\circ\text{C}$  indicated the evaporation of the remaining water in the catalysts. The wide decalescence valleys from  $500\text{ }^\circ\text{C}$  to  $700\text{ }^\circ\text{C}$  represented the transformation of  $MnO_2$  to  $Mn_2O_3$ , and the decalescence valleys from  $700\text{ }^\circ\text{C}$  to  $850\text{ }^\circ\text{C}$  represented the transformation of  $Mn_2O_3$  to  $Mn_3O_4$ .<sup>19–21</sup> In the DSC curve of 15% $MnO_x$ – $CoO_x$ (2 : 1)/ $TiO_2$  at  $271\text{ }^\circ\text{C}$ , there was a decalescence point and a weight-loss point, which indicated that  $Co_2O_3$  hydrate was dehydrated to  $Co_3O_4$ .<sup>20</sup> The continuous weight-loss from room temperature to approximately  $600\text{ }^\circ\text{C}$  confirmed that most of  $MnO_2$  probably existed in amorphous form and only a small amount of it might exist as crystallites.<sup>19</sup>

**3.1.3 XRD analysis.** XRD patterns were recorded to determine the crystal phases of the four catalysts and  $TiO_2$  carrier. As shown in Fig. 3, the distinct diffraction peaks of anatase  $TiO_2$  crystal (ICDD 01-089-4921) were detected on each catalyst and no characteristic peaks of  $CoO_x$  were found. However, very weak

characteristic peaks of  $Mn_2O_3$  were detected on 15% $MnO_x$ – $CoO_x$ (2 : 1)/ $TiO_2$  and 20% $MnO_x$ – $CoO_x$ (2 : 1)/ $TiO_2$  with higher loading of Mn oxides, and no diffraction peaks of  $MnO_2$  were detected. Combined with the results of TG-DSC analysis, it could be speculated that the crystallinity of  $MnO_2$  on the catalyst was very low and might exist primarily in an amorphous form. Manganic oxide species and cobalt oxide species were well-dispersed on the surface of catalysts and/or had poor crystal structure,<sup>22</sup> which would be beneficial to the catalytic reaction.<sup>23</sup> Average grain sizes calculated by the most intense reflexion characterizing of anatase  $TiO_2$  using Scherrer formula are listed in Table 1. Decrease in average grain size of anatase  $TiO_2$  carrier with the increase in loading of  $MnO_x$ – $CoO_x$  was probably due to that the increase in active components was not conducive to the agglomeration of the carrier crystal.

**3.1.4  $H_2$ -TPR analysis.** The results of  $H_2$ -TPR of the catalysts are displayed in Fig. 4.  $TiO_2$  carrier exhibited a reduction peak at  $611\text{ }^\circ\text{C}$ . For 7% $MnO_x$ – $CoO_x$ (2 : 1)/ $TiO_2$  and 10% $MnO_x$ – $CoO_x$ (2 : 1)/ $TiO_2$ , two reduction peaks were observed at  $332\text{ }^\circ\text{C}$  and  $490\text{ }^\circ\text{C}$ . The results of TG-DSC indicating  $MnO_2$  was present in the catalysts. According to the comparison of single supported catalyst and manganese cobalt co-supported catalyst in Fig. S3,<sup>†</sup> reduction peak at  $332\text{ }^\circ\text{C}$  could be assigned to the reduction of  $MnO_2$  to  $Mn_2O_3$ ,<sup>19</sup> and  $Co_3O_4$  to  $CoO$ .<sup>20</sup> The reduction peak at  $490\text{ }^\circ\text{C}$  was due to the reduction of  $Mn_2O_3$  occurred through  $Mn_3O_4$  to  $MnO$  (ref. 24) and the reduction of  $CoO$  to  $Co$ .<sup>20</sup> The interaction among metals might cause the reduction peaks changed in temperature or be covered by other peaks. For 15% $MnO_x$ – $CoO_x$ (2 : 1)/ $TiO_2$  and 20% $MnO_x$ –

Table 1 Physical parameters of catalysts

Catalyst	BET surface area ( $\text{m}^2 \text{ g}^{-1}$ )	Total pore volume ( $\text{cm}^3 \text{ g}^{-1}$ )	Average pore width (nm)	Average grain size ( $\text{\AA}$ )
$TiO_2$	102.90	0.43	18.26	211
7% $MnO_x$ – $CoO_x$ (2 : 1)/ $TiO_2$	95.86	0.41	16.13	156
10% $MnO_x$ – $CoO_x$ (2 : 1)/ $TiO_2$	94.47	0.39	15.90	155
15% $MnO_x$ – $CoO_x$ (2 : 1)/ $TiO_2$	88.29	0.33	15.02	152
20% $MnO_x$ – $CoO_x$ (2 : 1)/ $TiO_2$	82.04	0.30	14.70	149

Fig. 2 TG-DSC profiles of catalysts.

$\text{CoO}_x(2:1)/\text{TiO}_2$ , the reduction peak at 350 °C corresponded to the reduction of  $\text{MnO}_2$  to  $\text{Mn}_2\text{O}_3$  and  $\text{Co}_3\text{O}_4$  to  $\text{CoO}$ . According to Fig. S3,† the peak at 511 °C with a shoulder peak at 533 °C and the peak at 515 °C with a shoulder peak at 543 °C could be ascribed to the reduction of  $\text{CoO}$  to  $\text{Co}$  and the reduction of  $\text{Mn}_2\text{O}_3$  occurred through  $\text{Mn}_3\text{O}_4$  to  $\text{MnO}$ .<sup>19,20</sup> The reduction temperatures of  $\text{Mn}_2\text{O}_3$  and  $\text{CoO}$  on 15% $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$  catalyst were slightly lower than those of 20% $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$ , which meant that the reduction of  $\text{Mn}_2\text{O}_3$  and  $\text{CoO}$  on 15% $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$  occurred easier when compared to that of 20% $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$ . As shown in Table 2, the consumption of  $\text{H}_2$  gradually increased as the loading amount

increased, reflecting the improvement of redox performance with the increase in loading amount.

**3.1.5  $\text{O}_2$ -TPD analysis.**  $\text{O}_2$ -TPD results of the different loaded catalysts and  $\text{TiO}_2$  carrier are shown in Fig. 5. Except for  $\text{TiO}_2$ , all the samples exhibited two desorption ranges (100–500 °C and 500–900 °C). The desorption range below 500 °C corresponded to the desorption of chemisorption oxygen ( $\text{O}_\beta$ ), which was considered to be the desorption of oxygen species adsorbed on oxygen vacancies.<sup>25</sup> The desorption range above 500 °C was ascribed to the desorption of lattice oxygen ( $\text{O}_\alpha$ ).<sup>26</sup> The desorption peak temperatures of  $\text{O}_\alpha$  were almost corresponding to the decomposition temperature of manganese oxide in TG-DSC analysis. The quantities of  $\text{O}_2$  desorption of each sample are listed in Table 3. The quantities of low-temperature  $\text{O}_2$  desorption peaks ( $\text{O}_\beta$ ) increased with the loading of  $\text{MnO}_x$  and  $\text{CoO}_x$  and then decreased. The desorption

Fig. 3 XRD patterns of catalysts.

Fig. 4  $\text{H}_2$ -TPR profiles of catalysts.

Table 2  $H_2$  consumption of  $H_2$ -TPR

Catalyst	$H_2$ consumption ( $\mu\text{mol g}^{-1}$ )	
	Low-temperature peak (100–400 °C)	High-temperature peak (400–700 °C)
$\text{TiO}_2$	—	29
7% $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$	43	185
10% $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$	59	188
15% $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$	124	245
20% $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$	140	269

Fig. 5  $O_2$ -TPD profiles of catalysts.

quantity of chemisorption oxygen ( $O_\beta$ ) of 20% $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$  was significantly lower than that of 15% $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$ . This reflected that 15% $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$  might contain more oxygen vacancies to adsorb  $O_2$ , so it had the most desorption quantity of oxygen. Moreover, 15% $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$  demonstrated the lowest desorption peak temperature of chemisorption oxygen ( $O_\beta$ ). The lower desorption peak temperature of chemisorption oxygen ( $O_\beta$ ) and the more desorption quantity of  $O_\beta$  would be beneficial to the oxidation activity.<sup>27</sup>

**3.1.6 NO-TPD analysis.** The NO-TPD profiles of the four catalysts and  $\text{TiO}_2$  carrier are shown in Fig. 6. The desorption peaks of NO had two regions. The desorption peaks below 160 °C could be classified as weakly adsorbed species on the catalyst surface, such as physically adsorbed NO, monodentate nitrates and nitrites. The desorption peaks above 160 °C could be classified as bidentate nitrates and bridged nitrates, which had higher thermal stability.<sup>17,28</sup> The desorption and

decomposition of nitrates and nitrites will be discussed by *in situ* infrared spectroscopy *via* the thermal stability of nitrogen oxides adsorbed on the catalyst. Through NO-TPD profiles, it could be seen that with the increase in loading amount, the peak strength of NO desorption increased first and then decreased slightly, especially for the weakly adsorbed NO below 160 °C. The weakly adsorbed NO desorption peak on 15% $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$  was the largest when compared with other catalysts, indicating that 15% $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$  could adsorb more nitrate and nitrite species and participate in the oxidation reaction of NO, which is helpful to improve the oxidation efficiency of NO.

**3.1.7 XPS analysis.** The XPS spectra of Mn 2p, Co 2p and O 1s are shown in Fig. 7. In Fig. 7(a), the Mn 2p<sub>3/2</sub> could be resolved into three sub-bands: Mn<sup>2+</sup>, Mn<sup>3+</sup> and Mn<sup>4+</sup>.<sup>29,30</sup> The binding energies (eV) and valence composition ratios (%) of Mn (Mn<sup>n+</sup>/Mn) are listed in Table 4. As the loading amount increased, Mn<sup>2+</sup>/Mn ratio increased first and then decreased; hence, 15% $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$  contained the highest Mn<sup>2+</sup>/Mn ratio. However, the Mn<sup>4+</sup>/Mn ratio decreased with the increase in loading while Mn<sup>3+</sup>/Mn increased. The presence of Mn<sup>3+</sup> in manganese oxides could promote the formation of oxygen vacancies.<sup>31</sup> The Co 2p in Fig. 7(b) had two main peaks at around 796.0 eV and 780.0 eV, belonging to Co 2p<sub>1/2</sub> and Co 2p<sub>3/2</sub>, respectively. The satellite peaks at around 785.0–790.0 eV appeared representing the existence of Co<sup>2+</sup>.<sup>14</sup> The binding energies of Co<sup>2+</sup> and Co<sup>3+</sup> are very close, which need to be judged by the split energy level difference of the spin orbits.  $\Delta E(2p_{1/2} - 2p_{3/2}) = 16.0$  eV indicates that cobalt ions in the sample is mainly Co<sup>2+</sup>, while  $\Delta E(2p_{1/2} - 2p_{3/2}) = 15.0$  eV indicates that cobalt ions in the sample is mainly Co<sup>3+</sup>.<sup>14,32</sup> The binding energies (eV),  $\Delta E(2p_{1/2} - 2p_{3/2})$  and valence composition ratios (%) of Co (Co<sup>n+</sup>/Co) are listed in Table 5.  $\Delta E(2p_{1/2} -$

Table 3 Quantities of  $O_2$  desorption of  $O_2$ -TPD

Catalyst	Quantities of $O_2$ desorption ( $\mu\text{mol g}^{-1}$ )

Fig. 7 XPS spectra of catalysts. (a) and (d) Mn 2p; (b) and (e) Co 2p; (c) and (f) O 1s.

$2p_{3/2}$ ) of the fresh catalysts were 15.72–15.88 eV, indicating that cobalt ions in these catalysts were mainly  $\text{Co}^{2+}$ . Therefore, the peaks at around 780.27 eV could be classified as  $\text{Co}^{2+}$ , and the peaks at around 782.12 eV could be classified as  $\text{Co}^{3+}$ . As the loading amount increased,  $\Delta E(2p_{1/2} - 2p_{3/2})$  decreased first and then increase. It meant that the content of  $\text{Co}^{3+}$  increased first and then decreased, which corresponded to the  $\text{Co}^{3+}/\text{Co}$  ratio listed in Table 5.  $\text{Co}^{3+}/\text{Co}$  was the highest in 15% $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$  among all the catalysts, while the opposite trend was observed for  $\text{Co}^{2+}/\text{Co}$ . Fig. 7(c) shows the XPS spectra of O 1s. The corresponding binding energies (eV) and relative composition ratios (%) are listed in Table 6. The peaks at around 529.89 eV were assigned to lattice oxygen  $\text{O}_\alpha$ ,<sup>33</sup> and the peaks at around 531.55 eV were assigned to oxygen species  $\text{O}_\beta$ .

Table 4 Mn 2p<sub>3/2</sub> binding energies (eV) and valence composition (%)

Catalyst	Binding energies (eV)				Valence composition ratios (%)		
	Mn 2p <sub>3/2</sub>	Mn <sup>2+</sup>	Mn <sup>3+</sup>	Mn <sup>4+</sup>	Mn <sup>2+</sup> /Mn	Mn <sup>3+</sup> /Mn	Mn <sup>4+</sup> /Mn
7%MnO <sub>x</sub> –CoO <sub>x</sub> (2 : 1)/TiO <sub>2</sub>	642.08	641.41	642.48	645.34	10.54	44.25	45.21
10%MnO <sub>x</sub> –CoO <sub>x</sub> (2 : 1)/TiO <sub>2</sub>	642.08	641.42	642.50	645.36	15.18	50.13	34.69
15%MnO <sub>x</sub> –CoO <sub>x</sub> (2 : 1)/TiO <sub>2</sub>	642.07	641.40	642.50	645.32	17.11	53.39	29.50
20%MnO <sub>x</sub> –CoO <sub>x</sub> (2 : 1)/TiO <sub>2</sub>	642.07	641.42	642.49	645.32	9.56	67.07	23.37
15%MnO <sub>x</sub> –CoO <sub>x</sub> (2 : 1)/TiO <sub>2</sub> (O <sub>3</sub> )	642.09	641.44	642.53	645.30	10.71	55.72	33.57
15%MnO <sub>x</sub> –CoO <sub>x</sub> (2 : 1)/TiO <sub>2</sub> (NO)	642.07	641.40	642.55	645.28	42.27	46.26	11.47
15%MnO <sub>x</sub> –CoO <sub>x</sub> (2 : 1)/TiO <sub>2</sub> (NO + O <sub>3</sub> )	642.07	641.40	642.51	645.28	16.84	52.77	30.39

which were chemically adsorbed to oxygen vacancies.<sup>34</sup> With the increase in loading of MnO<sub>x</sub> and CoO<sub>x</sub>, the relative composition ratios of O<sub>x</sub>/O decreased first and then increased, while O<sub>B</sub>/O increased first and then declined. Consequently, O<sub>B</sub>/O was the highest in 15%MnO<sub>x</sub>–CoO<sub>x</sub>(2 : 1)/TiO<sub>2</sub> among all the catalysts. This variation trend was consistent with the result of O<sub>2</sub>-TPD, which confirmed that 15%MnO<sub>x</sub>–CoO<sub>x</sub>(2 : 1)/TiO<sub>2</sub> contained the largest amount of oxygen vacancies among the four catalysts, and was advantageous to adsorb oxygen species to be used in catalytic oxidation reaction.

The XPS spectra of the used 15%MnO<sub>x</sub>–CoO<sub>x</sub>(2 : 1)/TiO<sub>2</sub> catalyst after the separate adsorption of O<sub>3</sub> and NO, and the co-adsorption of O<sub>3</sub> and NO at 100 °C are shown in Fig. 7(d)–(f). From Fig. 7(d) and Table 4, it showed that Mn<sup>2+</sup>/Mn on the surface of 15% Mn–Co(2 : 1)/TiO<sub>2</sub> decreased significantly after O<sub>3</sub> adsorption, while Mn<sup>3+</sup>/Mn and Mn<sup>4+</sup>/Mn on the surface of 15% Mn–Co(2 : 1)/TiO<sub>2</sub> increased, which manifested that some of the manganese oxide were probably oxidized by O<sub>3</sub> through eqn (2) and (3).<sup>17</sup> While after NO adsorption, Mn<sup>3+</sup>/Mn and Mn<sup>4+</sup>/Mn on the surface of 15% Mn–Co(2 : 1)/TiO<sub>2</sub> decreased, but Mn<sup>2+</sup>/Mn increased. This illustrated that NO adsorbed on the catalyst probably reacted with manganese oxide in high valence state through eqn (4) and (5).<sup>17</sup> The changes in valence composition ratios of Mn<sup>2+</sup>/Mn, Mn<sup>3+</sup>/Mn and Mn<sup>4+</sup>/Mn on the surface of 15% Mn–Co(2 : 1)/TiO<sub>2</sub> were not significant after NO and O<sub>3</sub> co-adsorbed. It illustrated that the transformations among Mn<sup>2+</sup>, Mn<sup>3+</sup> and Mn<sup>4+</sup> in the NO catalytic oxidation process were almost in balance state. Similarly, Co<sup>3+</sup>/Co on the

surface of 15% Mn–Co(2 : 1)/TiO<sub>2</sub> increased while Co<sup>2+</sup>/Co decreased after O<sub>3</sub> adsorption, in Fig. 7(e) and Table 5, which was probably due to the reaction of eqn (6). Co<sup>2+</sup>/Co increased while Co<sup>3+</sup>/Co decreased after NO adsorption, which was probably due to the reaction of eqn (7). Simultaneous adsorption of O<sub>3</sub> and NO, the valence composition ratios of Co<sup>3+</sup>/Co and Co<sup>2+</sup>/Co were not changed obviously. It also illustrated that the transformations between Co<sup>3+</sup> and Co<sup>2+</sup> in the NO catalytic oxidation process were almost in balance state. The relative composition ratio of O<sub>B</sub>/O on the surface of 15% Mn–Co(2 : 1)/TiO<sub>2</sub> (in Fig. 7(f) and Table 6) increased after O<sub>3</sub> adsorption. O<sub>B</sub>/O decreased slightly after NO adsorption, which may be due to the consumption of chemisorption oxygen by NO reaction on the catalyst surface. After the co-adsorption of NO and O<sub>3</sub>, the change in relative composition ratio of O<sub>B</sub>/O was not obvious, illustrating that a balance state O<sub>B</sub> was set up during this process. It reflected that during the process of NO catalytic oxidation, reactive oxygen species decomposed from O<sub>3</sub> could adsorb on the oxygen vacancies of catalyst, which could supplement the chemisorption oxygen consumed by NO oxidation.

Table 5 Co 2p<sub>3/2</sub> binding energies (eV) and valence composition (%)

Catalyst	Binding energies (eV)				Valence composition ratios (%)	
	Co 2p <sub>3/2</sub>	ΔE(2p <sub>1/2</sub> – 2p <sub>3/2</sub> )	Co <sup>2+</sup>	Co <sup>3+</sup>	Co <sup>2+</sup> /Co	Co <sup>3+</sup> /Co
7%MnO <sub>x</sub> –CoO <sub>x</sub> (2 : 1)/TiO <sub>2</sub>	780.91	15.88	780.29	782.08	54.89	45.11

15%MnO <sub>x</sub> –CoO <sub>x</sub> (2 : 1)/TiO <sub>2</sub> (NO + O <sub>3</sub> )	529.90	529.89	531.55	75.73	24.27

### 3.2 NO oxidation properties

The results of NO oxidation efficiencies at different oxidation modes are shown in Fig. 8. With different loadings of MnO<sub>x</sub>–CoO<sub>x</sub>(2 : 1)/TiO<sub>2</sub>, NO oxidation efficiencies first increased with the increase in temperature, reaching the maximum value at 350 °C, and then decreased, as shown in Fig. 8(a). In the H<sub>2</sub>-TPR test, the low temperature reduction peak was around 332–350 °C, indicating that at the reaction temperature range of 50–400 °C, the active catalytic components were MnO<sub>2</sub> and Co<sub>3</sub>O<sub>4</sub>. 15%MnO<sub>x</sub>–CoO<sub>x</sub>(2 : 1)/TiO<sub>2</sub> exhibited the best catalytic efficiency, which can be owned to the best adsorption capacity of oxygen species by the results of O<sub>2</sub>-TPD and XPS. For NO oxidation only by O<sub>3</sub>, shown in Fig. 8(b), the efficiencies increased with the increase in O<sub>3</sub>/NO molar ratio, and decreased rapidly with the increase in temperature. Fig. 8(c) presents the NO oxidation efficiencies using varying loadings of MnO<sub>x</sub>–CoO<sub>x</sub>(2 : 1)/TiO<sub>2</sub> combined with O<sub>3</sub>/NO = 0.5. With the increase in temperature, NO oxidation efficiencies increased first (50–100 °C), then decreased (100–300 °C) and again increased from 300 °C to 350 °C, after then decreased again (350–400 °C). Because of the excellent low temperature oxidation performance of ozone and high temperature activity of catalyst, the efficiencies of NO oxidation by ozone combined with catalyst showed this trend with the change in temperature. The introduction of O<sub>3</sub> increased the NO oxidation efficiency, especially at low temperatures (<250 °C), when compared with NO catalytic oxidation by O<sub>2</sub> in Fig. 8(a). This could be ascribed to the good desorption ability of adsorbed oxygen O<sub>β</sub>, as seen from the results of O<sub>2</sub>-TPD, and the good oxidation performance of O<sub>3</sub> at low temperatures.

N<sub>2</sub> adsorption analysis showed that the specific surface area of the catalysts decreased with the increase in loading capacity. High specific surface area is helpful for the adsorption

performance of the catalyst.<sup>22,35</sup> However, as shown in Fig. 8(a) and (c), NO oxidation efficiencies increased with the total loading from 7% to 15%, which demonstrated that the loading amount or the content of active component was the main factor influencing the catalytic activity when compared to the specific surface area. The NO oxidation efficiency of 20%MnO<sub>x</sub>–CoO<sub>x</sub>(2 : 1)/TiO<sub>2</sub> was slightly lower than that of 15%MnO<sub>x</sub>–CoO<sub>x</sub>(2 : 1)/TiO<sub>2</sub>. Although the highest content of Mn<sup>3+</sup> was found in 20%MnO<sub>x</sub>–CoO<sub>x</sub>(2 : 1)/TiO<sub>2</sub>, which was favorable for the formation of oxygen vacancies due to the electrostatic balance,<sup>36</sup> 15%MnO<sub>x</sub>–CoO<sub>x</sub>(2 : 1)/TiO<sub>2</sub> had the highest Co<sup>3+</sup>/Co and chemisorption oxygen O<sub>β</sub> in XPS analysis. It is likely that the interaction of manganese–cobalt produced the most oxygen vacancies at loading amount of 15 wt%, which could adsorb more oxygen species, thereby promoting NO catalytic oxidation.<sup>37,38</sup> Therefore, NO catalytic oxidation efficiency of 15% MnO<sub>x</sub>–CoO<sub>x</sub>(2 : 1)/TiO<sub>2</sub> was slightly higher than that of 20% MnO<sub>x</sub>–CoO<sub>x</sub>(2 : 1)/TiO<sub>2</sub>. Fig. 8(d) presents the efficiencies of NO oxidation by O<sub>3</sub> (O<sub>3</sub>/NO = 0.1–0.9) over 15%MnO<sub>x</sub>–CoO<sub>x</sub>(2 : 1)/TiO<sub>2</sub>. Comparing Fig. 8(d) to Fig. 8(b), it was evident that NO oxidation efficiency was improved, especially in the high temperature region (250–400 °C). Therefore, the moderate concentration of O<sub>3</sub>/NO = 0.5 and 15%MnO<sub>x</sub>–CoO<sub>x</sub>(2 : 1)/TiO<sub>2</sub> were selected as the experimental condition in the following analyses.

The comparisons of NO oxidation efficiencies by different modes are shown in Fig. 8(e) and (f) shows the production of NO<sub>2</sub> by using different oxidation modes. In the experiment, the production of NO<sub>2</sub> was almost corresponding to the oxidation efficiency of NO, indicating that NO<sub>2</sub> was the main products when NO were oxidized by the methods of only using O<sub>2</sub> (4%), only using 15%MnO<sub>x</sub>–CoO<sub>x</sub>(2 : 1)/TiO<sub>2</sub> catalysts, only using O<sub>3</sub> (O<sub>3</sub>/NO = 0.5), and using 15%MnO<sub>x</sub>–CoO<sub>x</sub>(2 : 1)/TiO<sub>2</sub> combined with O<sub>3</sub> (O<sub>3</sub>/NO = 0.5). In Fig. 8(e), without O<sub>3</sub> and catalyst, the efficiencies of NO oxidation by O<sub>2</sub> were lower than 5.4%, and decreased with the increase in temperature. This is because NO + O<sub>2</sub> → NO<sub>2</sub> is an exothermic reaction and its spontaneous reaction is inefficient at low concentration of O<sub>2</sub>.<sup>39</sup> The oxidation efficiency of NO during oxidation by O<sub>3</sub> was much higher than that during catalytic oxidation by O<sub>2</sub> using 15%MnO<sub>x</sub>–CoO<sub>x</sub>(2 : 1)/TiO<sub>2</sub> when the temperature was below 250 °C,

**Fig. 8** NO oxidation efficiencies at different oxidation modes. (a) Different loadings of  $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$ ; (b)  $\text{O}_3/\text{NO}$ ; (c) different loadings of  $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$  combined with  $\text{O}_3/\text{NO} = 0.5$ ; (d) 15%  $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$  combined with  $\text{O}_3$ ; (e) comparison of NO oxidation by different modes; (f)  $\text{NO}_2$  yield by using different oxidation modes. Reaction conditions: flow = 400 mL min<sup>-1</sup>, NO = 500 ppm,  $\text{O}_2$  = 4%, GHSV = 24 000 h<sup>-1</sup>.

whereas the catalytic reaction occurred more easily above 250 °C. The efficiencies of NO during catalytic oxidation by  $\text{O}_3$  using 15%  $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$  were higher than that during either catalytic oxidation by  $\text{O}_2$  using 15%  $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$  or oxidation by  $\text{O}_3$  only. According to the placement of the catalyst in the reactor (Fig. S1†), when NO and  $\text{O}_3$  were simultaneously fed into the fixed-bed reactor, NO was first oxidized by  $\text{O}_3$ , and then the rest of NO was oxidized by  $\text{O}_2$  on the catalyst. The theoretical efficiency for combined oxidation was calculated using eqn (8):

$$(1 - \eta_{\text{O}_3}) \times \eta_{\text{catalyst}} + \eta_{\text{O}_3} \quad (8)$$

where, “ $\eta_{\text{O}_3}$ ” refers to the NO oxidation efficiency by  $\text{O}_3$  and “ $\eta_{\text{catalyst}}$ ” represents the NO oxidation efficiency by  $\text{O}_2$  using 15%  $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$ .

It can be seen from Fig. 7(e) that the measured efficiencies of NO oxidation by  $\text{O}_3$  ( $\text{O}_3/\text{NO} = 0.5$ ) using 15%  $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$  were 5–13% higher than the theoretical efficiencies calculated by eqn (8) below 250 °C, while the measured and theoretical efficiency values were very close above 300 °C. This result indicated that 15%  $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$  and  $\text{O}_3$  exerted a synergistic effect on NO oxidation at temperatures below 250 °C, while the synergistic effect was not evident above 250 °C. The synergistic mechanism between 15%  $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$  and  $\text{O}_3$  and its effect on NO oxidation will be discussed further in the later sections.

### 3.3 *In situ* DRIFTS studies

Fig. 9 presents the thermal stability of absorbed  $\text{NO}_x$  species after 15%  $\text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$  was exposed to different

Fig. 9 *In situ* DRIFTS data of absorbed  $\text{NO}_x$  species desorption as a function of temperature without fed gases after  $15\% \text{MnO}_x\text{--CoO}_x(2:1)/\text{TiO}_2$  was exposed to: (a) NO (500 ppm) for 30 min; (b) NO (500 ppm) +  $\text{O}_2$  (4%) for 30 min; (c) NO (500 ppm) +  $\text{O}_3$  ( $\text{O}_3/\text{NO} = 0.5$ ) for 30 min.

atmospheres. The fed gases were adsorbed on the catalyst surface at 25 °C for 30 min, then cut off the fed gases and conducted temperature desorption experiment. After NO adsorbed for 30 min at 25 °C, several peaks appeared at  $1619\text{ cm}^{-1}$ ,  $1568\text{ cm}^{-1}$ ,  $1319\text{ cm}^{-1}$ ,  $1213\text{ cm}^{-1}$  and  $1169\text{ cm}^{-1}$  on the surface of  $15\% \text{MnO}_x\text{--CoO}_x(2:1)/\text{TiO}_2$ , as shown in Fig. 9(a). The assignments of  $\text{NO}_x$  species are listed in Table 7. As the temperature increased, the peak at  $1619\text{ cm}^{-1}$  (bridging bidentate nitrates) gradually declined. The band at  $1568\text{ cm}^{-1}$  (bidentate nitrates) increased first and then decreased from 250 °C until it disappeared at 350 °C. The bands at  $1213\text{ cm}^{-1}$  and  $1169\text{ cm}^{-1}$  (nitrites) vanished at 100 °C. The band at  $1319\text{ cm}^{-1}$  (nitro-nitrito) gradually increased and shifted to  $1270\text{ cm}^{-1}$ . At 100 °C, the peak at  $1270\text{ cm}^{-1}$  (monodentate nitrates) appeared and then decreased with the increase in temperature. The bands at  $1325\text{ cm}^{-1}$  and  $1375\text{ cm}^{-1}$  (nitrate ions) gradually appeared from 200 °C and then declined from 300 °C, disappearing at 400 °C. The above results indicated that

bridging bidentate nitrates, bidentate nitrates, nitro-nitrito, and nitrites were formed at low temperatures, and nitrites were easy to decompose. Bridging bidentate nitrates were decomposed or desorbed with the increase in temperature. The transformation or decomposition of nitro-nitrito and unstable nitrates formed monodentate nitrates and decomposed above 150 °C, while bidentate nitrates were slightly more stable than monodentate nitrates. Nitrate ions gradually accumulated with the conversion of other absorbed  $\text{NO}_x$  species, which were thermally stable and did not decompose until above 300 °C.

After  $15\% \text{MnO}_x\text{--CoO}_x(2:1)/\text{TiO}_2$  co-adsorbed NO and  $\text{O}_2$  for 30 min at 25 °C, four peaks appeared at  $1601\text{ cm}^{-1}$ ,  $1571\text{ cm}^{-1}$ ,  $1435\text{ cm}^{-1}$ ,  $1317\text{ cm}^{-1}$  and  $1186\text{ cm}^{-1}$ , as shown in Fig. 9(b). The peaks at  $1601\text{ cm}^{-1}$  (bridging bidentate nitrates) and  $1571\text{ cm}^{-1}$  (bidentate nitrates) increased with the rise in temperature but started to weaken from 200 °C. The band at  $1435\text{ cm}^{-1}$  (monodentate nitrates) disappeared at 150 °C, and the band at  $1186\text{ cm}^{-1}$  (nitrites) almost disappeared at 50 °C. The band at

Table 7 Assignments of NO adsorbing species on  $15\% \text{MnO}_x\text{--CoO}_x(2:1)/\text{TiO}_2$  in *in situ* DRIFTS studies<sup>11,28,32,40–42</sup>

Assignment	Wavenumber (cm <sup>-1</sup> )
Bridging bidentate nitrates	$1619, 1609, 1608, 1600, 1602, 1601$
Bidentate nitrates	$1581, 1578, 1576, 1571, 1568, 1564, 1254, 1252, 1247, 1246, 1245$
Monodentate nitrates	$1516, 1512, 1445, 1435, 1297, 1293, 1286, 1285, 1270$
Nitrate ions	$1375, 1365, 1359, 1349, 1331, 1327, 1325,$
Nitro-nitrito	$1319, 1317$
Nitrites	$1213, 1203, 1186, 1169, 1167, 1149, 1144$

1317  $\text{cm}^{-1}$  (nitro-nitrito) moved to high wavenumber and a band at 1247  $\text{cm}^{-1}$  (bidentate nitrates) gradually appeared at 100  $^{\circ}\text{C}$ , and then faded away from 200  $^{\circ}\text{C}$ . With the transformation and decomposition of absorbed  $\text{NO}_x$  species, nitrate ions accumulate gradually at 1327  $\text{cm}^{-1}$ , and gradually moved to 1349  $\text{cm}^{-1}$ , which did not vanish at 400  $^{\circ}\text{C}$ . Comparing these results to Fig. 9(a), it was inferred that after 15% $\text{MnO}_x$ – $\text{CoO}_x$ (2 : 1)/ $\text{TiO}_2$  was exposed to NO and  $\text{O}_2$ , the desorption of absorbed  $\text{NO}_x$  species promoted the transformation of other nitrate species to bridging bidentate nitrates and bidentate nitrates, and also increased the accumulation of nitrate ions.

In Fig. 9(c), after 15% $\text{MnO}_x$ – $\text{CoO}_x$ (2 : 1)/ $\text{TiO}_2$  adsorbed NO and  $\text{O}_3$  for 30 min at 25  $^{\circ}\text{C}$ , four peaks appeared at 1609  $\text{cm}^{-1}$ , 1576  $\text{cm}^{-1}$ , 1445  $\text{cm}^{-1}$  and 1317  $\text{cm}^{-1}$ . The very distinct band at 1445  $\text{cm}^{-1}$  (monodentate nitrates) increased and shifted to 1512  $\text{cm}^{-1}$  as the temperature rose, and was almost covered by the band at 1576  $\text{cm}^{-1}$  (bidentate nitrates) at 100  $^{\circ}\text{C}$ . The peaks at 1609  $\text{cm}^{-1}$  (bridging bidentate nitrates) and 1576  $\text{cm}^{-1}$  (bidentate nitrates) increased with rise in temperature. Nevertheless, the peaks at 1609  $\text{cm}^{-1}$  and 1576  $\text{cm}^{-1}$  gradually declined above 150  $^{\circ}\text{C}$ . The band at 1317  $\text{cm}^{-1}$  (nitro-nitrito) moved to 1293  $\text{cm}^{-1}$  (monodentate nitrates) with the rise in temperature and declined from 150  $^{\circ}\text{C}$ . Moreover, the band at 1246  $\text{cm}^{-1}$  (bidentate nitrates) appeared at 100  $^{\circ}\text{C}$  and declined from 150  $^{\circ}\text{C}$ . The decomposition rate of monodentate nitrates was faster than that of bidentate nitrates. Comparing Fig. 9(a) and (b), it can be seen that the desorption of absorbed  $\text{NO}_x$  species, after 15% $\text{MnO}_x$ – $\text{CoO}_x$ (2 : 1)/ $\text{TiO}_2$  was exposed to NO and  $\text{O}_3$ , promoted the generation and transformation of monodentate nitrates and inhibited the formation of nitrate ions. Except for monodentate nitrates and nitrites at 1144–1213  $\text{cm}^{-1}$ , the decomposition of other absorbed  $\text{NO}_x$  species in Fig. 9(a) and (b) occurred at 200  $^{\circ}\text{C}$  or more, but the decomposition occurred at 150  $^{\circ}\text{C}$  in Fig. 9(c). Therefore, NO oxidation by  $\text{O}_3$  combined with 15% $\text{MnO}_x$ – $\text{CoO}_x$ (2 : 1)/ $\text{TiO}_2$  lowered the transformation and decomposition temperature of absorbed  $\text{NO}_x$  species, and inhibited the aggregation of nitrate ions on the catalyst surface. These effects were beneficial to the oxidation of NO.

*In situ* DRIFTS studies of  $\text{NO}_x$  adsorbed on 15% $\text{MnO}_x$ – $\text{CoO}_x$ (2 : 1)/ $\text{TiO}_2$  as a function of time were performed to reveal the effect of synergistic mechanism between 15% $\text{MnO}_x$ – $\text{CoO}_x$ (2 : 1)/ $\text{TiO}_2$  and  $\text{O}_3$  on NO oxidation. The fed gases were continued to introduce into the reaction cell for 1 h, and the infrared absorption spectra were recorded at intervals of one minute. Fig. 10(a) shows the temporal evolution of *in situ* DRIFTS curve during NO oxidation by  $\text{O}_2$  on 15% $\text{MnO}_x$ – $\text{CoO}_x$ (2 : 1)/ $\text{TiO}_2$  at 100  $^{\circ}\text{C}$  (NO = 500 ppm,  $\text{O}_2$  = 4%). After NO and  $\text{O}_2$  were introduced together into the DRIFTS cell, there was gradual appearance of peaks at 1609  $\text{cm}^{-1}$  (bridging bidentate nitrates), 1581  $\text{cm}^{-1}$  (bidentate nitrates), 1331  $\text{cm}^{-1}$  (nitrate ions), 1254  $\text{cm}^{-1}$  (bidentate nitrates), 1286  $\text{cm}^{-1}$  (monodentate nitrates), and 1203  $\text{cm}^{-1}$  (nitrites). The *in situ* DRIFTS curves in the range of 1100–1800  $\text{cm}^{-1}$  were fitted by Gauss function to obtain the area of each sub-peak (for example, the sub-peaks at 1609  $\text{cm}^{-1}$ , 1581  $\text{cm}^{-1}$ , 1331  $\text{cm}^{-1}$ , 1286  $\text{cm}^{-1}$ , 1254  $\text{cm}^{-1}$  and 1203  $\text{cm}^{-1}$ ). The maximum area of each sub-peak during the

first 30 minutes of reaction time was chosen as the standard. The relative intensity of each band was obtained by comparing the band area to the standard area. The slope of each relative intensity curve represented the rate of production or decomposition of each species. It can be seen clearly in Fig. 10(b) that the relative intensity of the peaks at 1609  $\text{cm}^{-1}$ , 1331  $\text{cm}^{-1}$  and 1286  $\text{cm}^{-1}$  progressively increased. Moreover, the peaks at 1581  $\text{cm}^{-1}$  and 1254  $\text{cm}^{-1}$  increased rapidly from 10 min and outpaced the other nitrate species. However, the peak at 1203  $\text{cm}^{-1}$  appeared quickly within 3 min, and then declined especially after 10 min. These results indicated that nitrites were transformed or decomposed, which accelerated the production of bidentate nitrates.

Fig. 10(c) shows the *in situ* DRIFTS curves during NO oxidation by  $\text{O}_3$  on 15% $\text{MnO}_x$ – $\text{CoO}_x$ (2 : 1)/ $\text{TiO}_2$  at 100  $^{\circ}\text{C}$  (NO = 500 ppm,  $\text{O}_2$  = 4%,  $\text{O}_3$ /NO = 0.5). The peaks at 1608  $\text{cm}^{-1}$  (bridging bidentate nitrates), 1578  $\text{cm}^{-1}$  (bidentate nitrates), 1516  $\text{cm}^{-1}$  (monodentate nitrates), 1297  $\text{cm}^{-1}$  (monodentate nitrates) and 1254  $\text{cm}^{-1}$  (bridging bidentate nitrates) appeared gradually. No characteristic peaks of nitrate ions and nitrites appeared which were consistent with the thermal stability test in Fig. 9(c). A new band appeared at 1516  $\text{cm}^{-1}$  (monodentate nitrates) in the  $\text{O}_3$  oxidation system at 100  $^{\circ}\text{C}$  compared to Fig. 10(a). The intensity of the peak at 1608  $\text{cm}^{-1}$  was higher than that of 1578  $\text{cm}^{-1}$  and intensity of the peak at 1297  $\text{cm}^{-1}$  was higher than that of 1254  $\text{cm}^{-1}$  in Fig. 10(c) when compared with Fig. 10(a). This might due to that  $\text{O}_3$  accelerated the generation of bridging bidentate nitrates at 1608  $\text{cm}^{-1}$ , which promoted the production of monodentate nitrates at 1516  $\text{cm}^{-1}$  and 1297  $\text{cm}^{-1}$ . The relative intensities of all species increased significantly within 10 min in Fig. 10(d), and then closed to adsorption saturation. By comparing the relative intensities in Fig. 10(b) and (d), it can be concluded that the oxidation of NO by  $\text{O}_3$  was much stronger than that by  $\text{O}_2$  on 15% $\text{MnO}_x$ – $\text{CoO}_x$ (2 : 1)/ $\text{TiO}_2$  at 100  $^{\circ}\text{C}$ .

Fig. 10(e) shows the *in situ* DRIFTS curves during NO oxidation by  $\text{O}_2$  on 15% $\text{MnO}_x$ – $\text{CoO}_x$ (2 : 1)/ $\text{TiO}_2$  at 350  $^{\circ}\text{C}$  (NO = 500 ppm,  $\text{O}_2$  = 4%). There were seven major bands located at 1600  $\text{cm}^{-1}$  (bridging bidentate nitrates), 1564  $\text{cm}^{-1}$  (bidentate nitrates), 1359  $\text{cm}^{-1}$  (nitrate ion), 1286  $\text{cm}^{-1}$  (monodentate nitrates), 1252  $\text{cm}^{-1}$  (bidentate nitrates), 1169  $\text{cm}^{-1}$  and 1144  $\text{cm}^{-1}$  (nitrites). When NO and  $\text{O}_2$  were simultaneously injected into DRIFTS cell at 350  $^{\circ}\text{C}$ , all the bands appeared quickly within 1 min, but did not increase significantly thereafter. This indicated that the reaction of NO and  $\text{O}_2$  on the surface of 15% $\text{MnO}_x$ – $\text{CoO}_x$ (2 : 1)/ $\text{TiO}_2$  at 350  $^{\circ}\text{C}$  was rapid. Fig. 10(f) shows the relative intensity of each band. It can be seen that the relative intensities of all the species remained greater than 60%, indicating that the accumulation and decomposition of all the intermediate products were in dynamic equilibrium.

Fig. 10(g) presents the *in situ* DRIFTS curves during NO oxidation by  $\text{O}_3$  on 15% $\text{MnO}_x$ – $\text{CoO}_x$ (2 : 1)/ $\text{TiO}_2$  at 350  $^{\circ}\text{C}$  (NO = 500 ppm,  $\text{O}_2$  = 4%,  $\text{O}_3$ /NO = 0.5). Similar to Fig. 10(e), seven peaks appeared within 1 min, including 1602  $\text{cm}^{-1}$  (bridging bidentate nitrates), 1578  $\text{cm}^{-1}$  (bidentate nitrates), 1365  $\text{cm}^{-1}$  (nitrate ion), 1285  $\text{cm}^{-1}$  (monodentate nitrates), 1245  $\text{cm}^{-1}$

**Fig. 10** *In situ* DRIFTS data of NO adsorbed on  $15\% \text{MnO}_x\text{-CoO}_x(2:1)/\text{TiO}_2$  as a function of time: (a)  $\text{NO} + \text{O}_2$  at 100 °C; (b) relative intensity of  $\text{NO} + \text{O}_2$  at 100 °C; (c)  $\text{NO} + \text{O}_3$  at 100 °C; (d) relative intensity of  $\text{NO} + \text{O}_3$  at 100 °C; (e)  $\text{NO} + \text{O}_2$  at 350 °C; (f) relative intensity of  $\text{NO} + \text{O}_2$  at 350 °C; (g)  $\text{NO} + \text{O}_3$  at 350 °C; (h) relative intensity of  $\text{NO} + \text{O}_3$  at 350 °C; (i) static reaction after NO and  $\text{O}_3$  adsorbed at 100 °C.

(bidentate nitrates), 1167  $\text{cm}^{-1}$  and 1149  $\text{cm}^{-1}$  (nitrites). The relative intensity of each intermediate species is presented in Fig. 10(h). All the bands in the presence of  $\text{O}_3$  at 350 °C rapidly

generated but then grew slowly. Therefore, it can be concluded that the effect of ozone on the intermediates formed during catalytic oxidation was weakened at high temperature, but it

Fig. 11 The pathway of NO oxidation by  $O_3$  ( $O_3/NO < 1$ ) over  $15\%MnO_x-CoO_x(2:1)/TiO_2$ .

still enhanced the NO catalytic oxidation. In addition, the peaks at  $1167\text{ cm}^{-1}$  and  $1149\text{ cm}^{-1}$  fluctuated greatly, indicating that there was partial decomposition of nitrites at  $350\text{ }^\circ\text{C}$  compared to that at  $100\text{ }^\circ\text{C}$ . Comparing the reaction of NO catalytic oxidation by  $O_3$  on  $15\%MnO_x-CoO_x(2:1)/TiO_2$  at  $100\text{ }^\circ\text{C}$  (Fig. 10(c)), there was no significant increase in monodentate nitrates around  $1516\text{ cm}^{-1}$  and  $1297\text{ cm}^{-1}$  during NO oxidation by  $O_2$  or  $O_3$  on  $15\%MnO_x-CoO_x(2:1)/TiO_2$  at  $350\text{ }^\circ\text{C}$  (Fig. 10(e) and (g)). In combination with the results of catalyst activity test, it was evident that the synergistic effect appeared only during NO oxidation by  $O_3$  ( $O_3/NO = 0.5$ ) on  $15\%MnO_x-CoO_x(2:1)/TiO_2$  below  $250\text{ }^\circ\text{C}$  (Fig. 8(e)). Thus, it can be speculated that monodentate nitrates were the pivotal intermediate products involved in the synergistic effect promoting the NO catalytic oxidation.

Fig. 10(i) presents the static reaction after NO and  $O_3$  co-adsorbed at  $100\text{ }^\circ\text{C}$  on  $15\%MnO_x-CoO_x(2:1)/TiO_2$ . The peaks at  $1608\text{ cm}^{-1}$  (bridging bidentate nitrates),  $1578\text{ cm}^{-1}$  (bidentate nitrates),  $1516\text{ cm}^{-1}$  (monodentate nitrates),  $1297\text{ cm}^{-1}$  (monodentate nitrates) and  $1254\text{ cm}^{-1}$  (bidentate nitrates) formed after NO and  $O_3$  co-adsorbed at  $100\text{ }^\circ\text{C}$  for 30 min. When all the gases were cut off and the adsorbed catalyst was left to stand for a period, the changes in the infrared absorption peaks of nitrate species were recorded. With the extension of the standing time, the characteristic peaks of bridging bidentate nitrates and bidentate nitrates at around  $1608-1578\text{ cm}^{-1}$  were significantly reduced, while the characteristic peaks of monodentate nitrates at  $1516\text{ cm}^{-1}$  and  $1297\text{ cm}^{-1}$  were enhanced, and the peak at  $1254\text{ cm}^{-1}$  was covered by the peak at  $1297\text{ cm}^{-1}$ . This indicated that bridging bidentate nitrates and bidentate nitrates could convert to monodentate nitrates.

From the *in situ* DRIFTS tests of  $NO_x$  desorption with increase in temperature, and the tests of NO oxidation by  $O_3$  or  $O_2$  using  $15\%MnO_x-CoO_x(2:1)/TiO_2$  at  $100\text{ }^\circ\text{C}$  and  $350\text{ }^\circ\text{C}$ , the transformations occurring between bridging bidentate nitrates, bidentate nitrates, monodentate nitrates and nitro-nitrito were determined. The results of characterization analyses showed that  $15\%MnO_x-CoO_x(2:1)/TiO_2$  contained oxygen vacancies, which could promote  $O_3$  to decompose an active oxygen atom at oxygen vacancy and desorbed an oxygen molecule.<sup>43</sup> After NO

reacted with active oxygen atom forming  $NO_2$ , the oxygen vacancy was available to adsorb the next active oxygen atom.<sup>17</sup> The pathway of NO catalytic oxidation by  $O_3$  using  $15\%MnO_x-CoO_x(2:1)/TiO_2$  is depicted in Fig. 11 and “□” represents oxygen vacancy.

In the *in situ* DRIFTS results of  $NO_x$  desorption shown in Fig. 9, nitro-nitrito was formed on the surface of  $15\%MnO_x-CoO_x(2:1)/TiO_2$  after NO was adsorbed at  $25\text{ }^\circ\text{C}$ . Therefore, NO was adsorbed on the active metal atom of the catalyst to form nitro-nitrito, which then reacted with the adsorbed oxygen to form other nitrate species. The rise in reaction temperature accelerated the transformation and decomposition of nitrate species, leading to the increase in NO oxidation efficiency. However, in the *in situ* DRIFTS curves of NO oxidation by  $O_3$  on  $15\%MnO_x-CoO_x(2:1)/TiO_2$  at  $100\text{ }^\circ\text{C}$  (Fig. 10(c)), nitro-nitrito could not be observed. This was because it transformed to other nitrate species at  $100\text{ }^\circ\text{C}$  (Fig. 9(c)), especially to monodentate nitrates. Mass-produced monodentate nitrates could decompose into gaseous  $NO_2$ , facilitating the oxidation of NO to  $NO_2$ . This could be the reason for the synergistic effect on NO oxidation by  $O_3$  using  $15\%MnO_x-CoO_x(2:1)/TiO_2$  at low temperature.

## 4. Conclusions

In this work,  $TiO_2$ -supported catalysts with various loading amounts of  $MnO_x-CoO_x$  (molar ratio of Mn to Co = 2 : 1) were prepared and evaluated in the oxidation of NO in presence of low ratio of  $O_3$  ( $O_3/NO < 1$ ). It was found that  $15\%MnO_x-CoO_x(2:1)/TiO_2$  displayed the optimal catalytic oxidation of NO due to its good redox performance, high surface oxygen mobility, most oxygen vacancies and chemisorbed oxygen. The NO oxidation efficiency was increased by  $O_3$  ( $O_3/NO < 1$ ) combined with  $15\%MnO_x-CoO_x(2:1)/TiO_2$  at  $50-400\text{ }^\circ\text{C}$ , especially below  $250\text{ }^\circ\text{C}$ . The synergistic effect of NO oxidation efficiency in the presence of  $O_3$  ( $O_3/NO < 1$ ) over  $15\%MnO_x-CoO_x(2:1)/TiO_2$  was observed below  $250\text{ }^\circ\text{C}$ . The results of *in situ* DRIFTS studies confirmed that  $O_3$  accelerated the transition between nitrate species, reduced the decomposition temperature of nitrate species, speeded up the rate of NO oxidation and

inhibited the formation of nitrate ions. Below 250 °C, the mass-produced monodentate nitrates were responsible for the synergistic enhancement when both 15% $\text{MnO}_x\text{-CoO}_x$ (2 : 1)/ $\text{TiO}_2$  and  $\text{O}_3$  were present. This conclusion can provide theoretical basis for the study of NO catalytic oxidation by low concentration ozone in the future.
