Ultrasonic-assisted preparation of highly active $\text{Co}_3\text{O}_4/\text{MCM-41}$ adsorbent and its desulfurization performance for low H_2S concentration gas

 Bolong Jiang,^{a*} Jiaojing Zhang,^b Yanguang Chen,^b Hua Song,^{a*} Tianzhen Hao^c and Junhu Kuang^d

$\text{Co}_3\text{O}_4/\text{MCM-41}$ adsorbents were successfully prepared by ultrasonic assisted impregnation (UAI) and traditional mechanical stirring impregnation (TMI) technologies and characterized by X-ray diffraction (XRD), N_2 adsorption desorption, Fourier transform infrared spectra (FT-IR), transmission electron microscopy (TEM), scanning electron microscopy (SEM) and thermogravimetry-differential thermal analysis (TG-DTA). The H_2S removal performances for a simulated low H_2S concentration gas were investigated in a fixed-bed. The effect of preparation and adsorption conditions on the H_2S removal over $\text{Co}_3\text{O}_4/\text{MCM-41}$ were systematically examined. The results showed that UAI promotes more and well defined highly dispersed active Co_3O_4 phase on MCM-41. As compared to the $\text{Co}_3\text{O}_4/\text{MCM-41-T}$ prepared via TMI, the saturated H_2S capacity of $\text{Co}_3\text{O}_4/\text{MCM-41-U}$ prepared via UAI improved by 33.2%. The desulfurization performance of adsorbents decreased in the order of $\text{Co}_3\text{O}_4/\text{MCM-41-U} > \text{Co}_3\text{O}_4/\text{MCM-41-T} > \text{MCM-41}$. The $\text{Co}_3\text{O}_4/\text{MCM-41-U}$ prepared using $\text{Co}(\text{NO}_3)_2$ concentration of 10%, ultrasonic time of 2 h, calcination temperature of 550 °C and calcination time of 3 h exhibited the best H_2S removal efficiency. At adsorption temperature of 25 °C with model gas flowrate of 20 mL min^{-1} , the breakthrough time of $\text{Co}_3\text{O}_4/\text{MCM-41-U}$ was 10 min, and the saturated H_2S capacity and H_2S removal rate was 52.6 mg g^{-1} and 47.8%, respectively.

1 Introduction

Industrial processes have produced large amount of hazardous materials which are harmful for humans and the environment.^{1,2} Hydrogen sulfide (H_2S) with its characteristic rotten egg smell is often present in a variety of hydrocarbon resources such as natural gas and biogas.³ H_2S is a poisonous, corrosive and flammable colorless gas. Therefore, removing this poisonous gas from hydrocarbon resources is an important global concern.⁴

Currently, methods of H_2S removal from hydrocarbon resources are mainly wet and dry desulfurization. An alcohol amine solution is commonly used in industrial H_2S absorption.^{5,6} However, disadvantages of this method for industrial application are large investment and high energy consumption. Comparatively, the dry method is preferred over the wet method

in terms of cost and environmental considerations. Moreover, adsorption is known as one of the most efficient candidates to adsorb H_2S from low H_2S concentration gases owing to its ability to produce a very low H_2S level gas under moderate conditions.⁷ So far, several types of adsorbents such as zeolites, activated carbons, metal organic frameworks, clays and molecular sieves have been investigated in dry adsorption of H_2S .^{8,9} However, low sulfur capacity and selectivity of these unmodified adsorbents requires frequent regeneration of spent adsorbents.¹⁰ In this concern, developing an adsorbent with a high sulfur capacity to achieve the targeted removal and a long lifetime are of great important.¹¹ Metal oxides, such as iron, zinc, manganese, copper and calcium oxides, have been widely investigated for H_2S removal.^{12–14} Metal oxides adsorb H_2S via a chemical reaction, which produces a metal sulfide. However, using metal oxides directly in their pure forms has several drawbacks. The main drawbacks are the difficult recovering and reusability properties, low adsorption properties owing to the low surface area and poor mass transfer ability of metal oxides, which limits their application for H_2S removal. An effective way to address the above drawbacks is to support metal oxides on high surface supports.¹⁵ Therefore, transition metal oxides loaded on proper supports have been widely investigated.¹⁶ The MCM-41 is commonly used as support in catalyst field, due to its high surface area, tunable pore diameter and large pore

volume.^{17,18} However, unmodified MCM-41 is poor in desulfurization due to the main adsorption way of which is physical adsorption. In this regard, supporting active metal oxide on MCM-41 porous materials is expected to be an effective way to take full advantages of metal oxides and MCM-41.^{10,19}

It is well known that loading method would greatly affect the dispersion of metal oxide on surface of support, which in turn affect its H₂S removal performance.²⁰ Ultrasonic assisted impregnation (UAI) has recently received much attention as its unique dispersion properties. The dispersion of active metal oxides on surface of support can be greatly improved by using this technique because ultrasonic wave can produce a powerful microjet flow through its “cavitation effect”, which in turn produce a great impact on the support.²¹ In addition, the harsh operating conditions (such as high temperatures), which usually needed to achieve a better dispersion for traditional mechanical stirring impregnation (TMI) methods, are not required. Mi *et al.*²² reported that as compared to TMI method, metal oxides can more evenly be dispersed in char when the UAI technology was applied.

Cobalt oxide, as well as its based composites, was investigated extensively as potential materials in many fields.²³ Silas *et al.*²⁴ synthesized activated carbon monolith supported tricobalt tetraoxide (Co₃O₄) adsorbent (Co₃O₄/ACM) for simultaneous SO₂/NO_x removal from flue gas and found that the Co₃O₄/ACM adsorbent exhibited a high affinity to NO_x adsorption. Therefore, it is reasonable to expect that combining the advantage of Co₃O₄ and high surface mesoporous MCM-41, coupled with UAI technology, might yield unexpected adsorbent for efficient H₂S removal. However, to the best of our knowledge, adsorbents based on Co₃O₄ supported on MCM-41 prepared by UAI for the H₂S removal from natural gas have not been reported. Therefore, we believe that Co₃O₄/MCM-41 adsorbent prepared by UAI method is worth studying.

In the present work, Co₃O₄/MCM-41 was prepared by UAI and TMI technologies, and their adsorptive removal performances for a simulated low H₂S concentration gas were investigated. As expected, Co₃O₄/MCM-41 prepared by UAI technology exhibited much higher surface area and H₂S removal performance. In addition, the effect of preparation and adsorption conditions on the H₂S removal performance of Co₃O₄/MCM-41 were systematically examined.

2 Experimental

2.1 Adsorbents preparation

The cobalt oxide supported mesoporous MCM-41 was prepared by ultrasonic assisted impregnation (UAI) method (Scheme 1). First, 1 g of precalcined MCM-41 (all-silicon, Nankai University Catalyst Factory) was dispersed in 25 mL cobalt nitrate (Co(NO₃)₂·6H₂O) solution with cobalt nitrate concentration of 10% and treated by ultrasonic wave for 2 h. The suspension was then filtered and washed with ethanol (Haerbin Chemical Reagent Company) and distilled water in turn, followed by drying in the oven at 110 °C for 12 h. Then the solid was transferred to muffle furnace and calcined at 550 °C for 3 h. The

Scheme 1 Schematic diagram for the synthesis of Co₃O₄/MCM-41-U via ultrasonic assisted impregnation.

obtained sample named as Co₃O₄/MCM-41-U, where U means prepared by UAI method. For comparison, the Co₃O₄/MCM-41 was also prepared by traditional impregnation (mechanical stirring for 24 h) method (TMI) with other conditions remained unchanged, which denoted as Co₃O₄/MCM-41-T. The Co₃O₄/MCM-41-U samples were also prepared at different conditions by varying the cobalt nitrate concentration (5%, 8%, 10%, 13% and 15%), ultrasound time (1.5 h, 2 h, 2.5 h and 3 h), calcination temperature (350 °C, 450 °C, 550 °C and 650 °C) and time (2 h, 3 h, 4 h and 5 h).

2.2 Characterization

The X-ray diffraction (XRD) measurement and analysis were obtained from X-ray diffractometer (a D/max-2200PC-X-ray diffractometer) by using Cu K α radiation conducted at 40 kV, 30 mA, and a scan range from 10° to 80° at a rate of 10° min⁻¹. The typical physicochemical properties of the supports and catalysts were analyzed by N₂-adsorption specific surface area measurements using the Brunauer–Emmett–Teller (BET, Micromeritics, NOVA 2000e: Surface Area & Pore Size Analyzer). The Fourier transform infrared spectra (FT-IR) of the catalysts were recorded with a Brook Tensor 27 Fu Liye infrared spectrometer in the optical range of 400–4000 cm⁻¹. The thermal stability of adsorbent was analyzed by (TG-DTA DuPont 2100) with heating rate: 10 K min⁻¹ under the protect flow of 20 mL min⁻¹. The reducibility of precursors was characterized by the H₂ temperature-programmed reduction (H₂-TPR) using (CHEMBET-3000, Quantachrome) a quartz U-tube reactor (inner diameter of 6 mm). Reduction was conducted at a heating rate of 10 K min⁻¹ in a 5 vol% H₂/N₂ flow (30 mL min⁻¹).

2.3 Fixed-bed ADS experiment

Measurements of adsorbent activity were conducted in a fixed-bed reactor (Scheme 2). The fixed-bed reactor (a quartz glass

Scheme 2 Schematic diagram of the experimental apparatus.

tube with diameter of 10 mm and length of 300 mm) placed vertically in a furnace. Typically, 0.2 g adsorbent was loaded into the reactor. The model fuel gas (H_2S , N_2 and O_2 mixture; N_2 as balance gas; the H_2S concentration was 20 mg L^{-1}) from a feed tank passed through a reducing valve and entered into the reactor at a flowrate of 20 mL min^{-1} . Any unadsorbed H_2S gas in the effluent gas would be absorbed by the liquid in the absorption bottle, and the H_2S content of the absorption liquid was determined by iodometry at intervals of 5 min. The saturated H_2S capacity and H_2S removal rate of the adsorbent were calculated by the analysis of H_2S breakthrough curves.

The saturated H_2S capacity is defined as the amount of adsorbed H_2S per gram of adsorbent when the H_2S concentrations in the effluent and in the initial gas are the same. It can be calculated as follows.¹⁰

$$q_m = \frac{V \times \omega_{\text{H}_2\text{S}} - (c_1 v_{\text{I}_2} - 0.5c_{\text{Na}_2\text{S}_2\text{O}_3} v_{\text{Na}_2\text{S}_2\text{O}_3}) \times 34}{m} \quad (1)$$

where q_m is the saturated H_2S capacity, mg g^{-1} ; ω is the H_2S concentration in the model gas, mg L^{-1} ; V is the total gas volume, L; c is the concentration in mol L^{-1} ; v is the volume in L; m is amount of adsorbent, g; and 34 is the molar mass of H_2S in g mol^{-1} .

The H_2S removal rate η can be expressed as

$$\eta = \frac{V \times \omega_{\text{H}_2\text{S}} - (c_1 v_{\text{I}_2} - 0.5c_{\text{Na}_2\text{S}_2\text{O}_3} v_{\text{Na}_2\text{S}_2\text{O}_3}) \times 34}{V \times \omega_{\text{H}_2\text{S}}} \times 100\% \quad (2)$$

2.4 Calculation of mass transfer zone

The mass transfer zone (MTZ) can be defined as the following equation:²⁵

$$\text{MTZ} = \frac{(\tau_e - \tau_a)}{\tau_e} \times Z_0 \quad (3)$$

where MTZ is the mass transfer zone with the unit of mm; τ_a is the breakthrough time to reach $c/c_0 = 0.10$; τ_e is the saturated adsorption time to reach $c/c_0 = 0.95$; Z_0 stands for the height of fixed bed column with the unit of mm (300 mm in this study).

3 Results and discussion

3.1 Characterization of adsorbents

3.1.1 XRD. As can be seen in Fig. 1, all the samples showed a strong broad peak at $2\theta = 15\text{--}30^\circ$ due to the amorphous nature of mesoporous MCM-41, showing the mesopores of MCM-41 were retained after successive impregnation and high temperature calcination.^{26,27} The $\text{Co}_3\text{O}_4/\text{MCM-41-T}$ which prepared by traditional impregnation (TMI) method showed diffraction peaks at $2\theta = 36.8^\circ$, 44.8° , 59.3° and 65.2° , which corresponded the cubic phase Co_3O_4 lattice planes of (311), (400), (511) and (440) [PDF # 23-1003]²⁸, respectively. For the $\text{Co}_3\text{O}_4/\text{MCM-41-U}$ which obtained *via* ultrasonic assisted impregnation (UAI) method, the diffraction peaks at $2\theta = 19^\circ$, 31.27° , 36.8° , 38.5° , 44.8° , 55.6° , 59.3° and 65.2° were observed, which can be assigned to the cubic phase Co_3O_4 lattice planes of (111), (220), (311), (222), (400), (422), (511) and (440),

Fig. 1 XRD patterns of blank MCM-41 and adsorbents prepared by different methods. (1) MCM-41, (2) $\text{Co}_3\text{O}_4/\text{MCM-41-T}$ and (3) $\text{Co}_3\text{O}_4/\text{MCM-41-U}$.

respectively.²⁹ This demonstrated that the cobalt oxide obtained by calcination the precursor was Co_3O_4 phase. It is interesting to note that all the diffraction peaks of the as-synthesized Co_3O_4 can be seen for $\text{Co}_3\text{O}_4/\text{MCM-41-U}$, but some peaks were disappeared for $\text{Co}_3\text{O}_4/\text{MCM-41-U}$, showing the UAI produce more and well defined regularly sorted Co_3O_4 crystal phase.

3.1.2 BET. The nitrogen adsorption isotherms, pore size distributions and textural properties of MCM-41, $\text{Co}_3\text{O}_4/\text{MCM-41-T}$ and $\text{Co}_3\text{O}_4/\text{MCM-41-U}$ are shown in Fig. 2 and Table 1. According to the new IUPAC technical report,³⁰ the isotherms of the these three samples identified as type IV isotherms, which is characteristic of microporous materials. And the hysteresis loop is classified as H1 type, which corresponds to the tubular pore model with openings at both ends.³¹ However, the inflection pressure and the slope of these curves at each stage are somewhat different after loading of Co_3O_4 . From the position of the hysteresis loop appeared, the average diameter of the pores can be estimated approximately 3 nm, which was consistent with

Fig. 2 N_2 adsorption–desorption isotherm (a) and BJH pore size distribution (b) of blank MCM-41 and adsorbents prepared by different methods.

Table 1 The pore structures of blank MCM-41 and adsorbents prepared by different methods

Sample	Surface area (m ² g ⁻¹)	Pore volume (cm ³ g ⁻¹)	Pore diameter (nm)
MCM-41	1140.7	1.07	3.74
Co ₃ O ₄ /MCM-41-T	648.6	0.45	2.75
Co ₃ O ₄ /MCM-41-U	919.2	0.67	2.93

the average pore diameter of 3.74, 2.75 and 2.93 nm (see Table 1), respectively. The low pressure hysteresis loop can be considered to be caused by capillary condensation of N₂ in the straight channel of MCM-41 itself.³² The high pressure hysteresis loop may be caused by capillary condensation of N₂ between interparticles of MCM-41.³³ For Co₃O₄/MCM-41-T and Co₃O₄/MCM-41-U, the hysteresis loop within the p/p_0 range of 0.45–0.65 indicates the ordered structure and uniform mesoporous channel of the MCM-41 were retained after loading of Co₃O₄. These results are consistent with the XRD results. As can be seen from Fig. 2 that the pores of blank MCM-41 were ranged in 2–5 nm. Upon loading of Co₃O₄ on MCM-41, the pore size decreased, showing the Co₃O₄ entered into the pores. The specific surface area and pore volume of blank MCM-41 were up to 1095.2 m² g⁻¹ and 1.22 cm³ g⁻¹ (Table 1). The loading of Co₃O₄ caused the decrease in specific surface area and pore volume. However, the decrease was less severe for Co₃O₄/MCM-41-U than that of Co₃O₄/MCM-41-T, which possibly because the UAI promotes evenly dispersed small Co₃O₄ particles on surface of the MCM-41.²¹

3.1.3 FT-IR. The surface functional groups on the samples were examined by Fourier-transform infrared (FTIR) spectra (Fig. 3). The similarity of the FTIR spectra of these three samples, featured the absorption peaks at the same wavelengths, showed that the types of functional groups of MCM-41 were basically remained after modification.³⁴ For MCM-41, the peak appeared at 1634 cm⁻¹ can be attributed to physically adsorbed water. However, the intensity of this peak was reduced for Co₃O₄/MCM-41-T and Co₃O₄/MCM-41-U, showing the loss of water.³⁵ The characteristic peaks at 450, 807, 1085 and 1250 cm⁻¹ is classified as the vibration of Si–O–Si.³⁶ For Co₃O₄/MCM-41-T and Co₃O₄/MCM-41-U, a new absorption peaks

**Fig. 3** The H₂-TPR profiles of blank MCM-41 and adsorbents prepared by different methods. (1) MCM-41, (2) Co₃O₄/MCM-41-T and (3) Co₃O₄/MCM-41-U.**Fig. 4** TG-DTA curves of Co₃O₄/MCM-41 precursor without calcination.

appeared at 960 cm⁻¹ as compared to the blank MCM-41. For the appearance of this shoulder peak, two different points of view have been proposed. Some researchers suggested that it is owing to the introduction of the heteroatom in the skeleton, while others suggested that it is owing to the asymmetry of the partial skeleton structure arising from defect sites.³⁷ Moreover, the new absorption peaks appeared at 660 cm⁻¹ and 562 cm⁻¹ belong to the stretching vibration of spinel phase Co–O in Co₃O₄,^{38,39} which confirms the formation of Co₃O₄. It should be noted that the intensities of these two peaks of Co₃O₄/MCM-41-U were obviously stronger than those of Co₃O₄/MCM-41-T, showing UAI promotes formation of more Co₃O₄ crystal active phase.

3.1.4 TG-DTA. The TG-DTA curve of Co₃O₄/MCM-41-U is shown in Fig. 4. For temperature range of 0–150 °C, the TG curve showed a weight loss of 14.3%, which corresponds to a strong endothermic peak in DTA curve. This weight loss can be assigned to the elimination of adsorbed water from the surface and pores.⁴⁰ While for the temperature range of 150–260 °C, the TG curve exhibited a weight loss of 18.7%, which corresponds to a sharp exothermic peak in DTA curve. This weight loss can be assigned to the decomposition of Co(NO₃)₂ in precursor to Co₃O₄. For the temperature higher than 260 °C to 650 °C, the weight loss became extremely slow (6.3%). This weight loss can be assigned to the sintering or decomposition of components and dehydration of adsorbent at high temperature.⁴¹

**Fig. 5** The H₂-TPR profiles of blank MCM-41 and adsorbents prepared by different methods. (1) MCM-41, (2) Co₃O₄/MCM-41-T and (3) Co₃O₄/MCM-41-U.

3.1.5 TPR. Fig. 5 shows the H₂-TPR curves of these three samples. It can be observed that two reduction peaks presented at temperature range of 100–600 °C. The reduction peak at lower temperature of 354 °C can be ascribed to the H₂ consumption due to the reduction of Co₃O₄ to CoO, while the reduction peak at higher temperature of 383 °C can be ascribed to the H₂ consumption owing to the reduction of CoO to Co.⁴² The corresponding reduction reactions are shown as follows:

It should be noted that the intensity of these two peaks of Co₃O₄/MCM-41-U was obviously stronger than those of Co₃O₄/MCM-41-T, showing UAI promotes formation of more Co₃O₄ crystal active phase. This observations are consistent with the results obtained in the FT-IR.

3.2 Adsorptive desulfurization

3.2.1 Effect of preparation methods. The adsorbents were evaluated at 25 °C with model gas flowrate of 20 mL min⁻¹ in the fixed-bed reactor using 0.2 g of adsorbent (Fig. 6). It can be seen that the breakthrough time of blank MCM-41 is the shortest. Upon loading of Co₃O₄ on MCM-41, the breakthrough time extended, showing loading of Co₃O₄ can enhance the H₂S removal efficiency. The saturated H₂S capacity of adsorbent showed similar trends. The saturated H₂S capacity of Co₃O₄/MCM-41-T and Co₃O₄/MCM-41-U were 18.4 and 24.5 mg g⁻¹, respectively, which are increased by 23.5% and 64.4% as compared to that of the original MCM-41. It should be noted

Scheme 3 Explanation for the improved H₂S removal efficiency over Co₃O₄/MCM-41-U.

that the Co₃O₄/MCM-41-U prepared *via* UAI showed a better H₂S removal performance than that of Co₃O₄/MCM-41-T prepared *via* TMI. This is possibly because UAI promotes more and well defined highly dispersed active Co₃O₄ phase (see XRD, FT-IR and TPR analysis) loading on the MCM-41 due to its “cavitation effect”, and therefore would lead to a higher H₂S removal efficiency (Scheme 3). Moreover, Co₃O₄/MCM-41-U possessed a higher surface area (BET analysis) as compared to that of Co₃O₄/MCM-41-T, which facilitate exposure more active sites to H₂S. The similar results were observed by Dou,²¹ who found that Fe–Zn supported on activated-char *via* UAI showed much better performance than that *via* TMI. They explained that UAI enhanced the chemical reaction and mass transfer *via* acoustic cavitation during preparation process,⁴³ which can improve the H₂S removal performance. The H₂S removal performance of the adsorbents decreased in the order of Co₃O₄/MCM-41-U > Co₃O₄/MCM-41-T > MCM-41.

Fig. 6 H₂S breakthrough curves (a) and saturated H₂S capacity and desulfurization rate (b) of samples prepared by different methods.

Fig. 7 H₂S breakthrough curves (a) and saturation sulfur capacity and desulfurization rate (b) of Co₃O₄/MCM-41-U prepared using different cobalt nitrate concentration.

3.2.2 Effect of preparation conditions. All of the adsorbents were evaluated at adsorption temperature of 25 °C with model gas flowrate of 20 mL min⁻¹ in the fixed-bed reactor using 0.2 g of adsorbent in this section. The effect of concentration of Co(NO₃)₂ on performance of H₂S removal over Co₃O₄/MCM-41-U is shown in Fig. 7. With increasing the concentration of Co(NO₃)₂, the breakthrough and saturated adsorption time both increased first and then decreased, reached the maximums at Co(NO₃)₂ concentration of 10%, which are 7 min and 53 min, respectively. This is possibly because that for the very low Co(NO₃)₂ concentration, the loading of active Co₃O₄ on adsorbent would be low, which in turn led to a poor H₂S adsorption. However, with an excess of active Co₃O₄ loading, the agglomeration of Co₃O₄ and blockage of some pores of adsorbent would occur, which could decrease the H₂S removal performance. The saturated H₂S capacity and desulfurization rate of adsorbents exhibited the similar trends, which shows the maximum saturated H₂S capacity and desulfurization rate of 38.7 and 45.1%, respectively, at Co(NO₃)₂ concentration of 10%.

The effect of ultrasonic time on performance of H₂S removal over Co₃O₄/MCM-41-U with Co(NO₃)₂ concentration of 10% remained unchanged is shown in Fig. 8. With increasing the ultrasonic time, the breakthrough and saturated adsorption time both increased first and then decreased, reached the maximums at ultrasonic time of 2 h, which are 7 min and 53 min, respectively. Ultrasonic wave, can produce a powerful microjet flow *via* its “cavitation effect”, which in turn can produce a great impact on the support. As a results, the active components can be more evenly dispersed in the support channel, and thus UAI improves the H₂S removal activity. However, when ultrasonic time is too long, it would causes

a local accumulation of Co species at the standing wave node of ultrasonic and lead to a poor dispersion of active Co₃O₄ on support, which in turn decreases the H₂S removal performance. The saturated H₂S capacity and desulfurization rate of adsorbents exhibited the similar trends, which shows the maximum saturated H₂S capacity and desulfurization rate of 38.7 and 45.1%, respectively, at ultrasonic time of 2 h.

The effect of calcination temperature on performance of H₂S removal over Co₃O₄/MCM-41-U with Co(NO₃)₂ concentration of 10% and ultrasonic time of 2 h remained unchanged is shown in Fig. 9. With increasing the calcination temperature, the breakthrough and saturated adsorption time both increased first and then decreased, reached the maximums at calcination temperature of 550 °C, which are 7 min and 53 min, respectively. The calcination is a thermal treatment process which will bring about a thermal decomposition, phase transition, or removal of a volatile fraction. The TG-DTA analysis is evident that the decomposition of Co(NO₃)₂ occurred between 150–260 °C and continued weight loss till 650 °C owing to the sintering or decomposition of components at high temperature. From XRD analysis, it can be known that at 550 °C, the metal oxide was well defined Co₃O₄ crystal phase, which is high in activity. Further increase the calcination temperature would cause the sintering, which would lead to an aggregation of active Co₃O₄ and thus poor H₂S removal efficiency.⁴⁴ The saturated H₂S capacities of the adsorbents decreased in the order: 550 °C > 450 °C > 650 °C > 350 °C. The calculated values were 38.7, 26.2, 26.1 and 23.5 mg g⁻¹, respectively. The saturated H₂S capacity and desulfurization rate of adsorbents exhibited the similar trends, which shows the maximum saturated H₂S

capacity and desulfurization rate of 38.7 and 45.1%, respectively, at calcination temperature of 550 °C.

The effect of calcination time on performance of H_2S removal over $Co_3O_4/MCM-41-U$ with $Co(NO_3)_2$ concentration of 10%, ultrasonic time of 2 h and calcination temperature of 550 °C remained unchanged is shown in Fig. 10. With increasing the calcination time, the breakthrough and saturated adsorption time both increased first and then decreased, reached the maximums at calcination time of 3 h, which are 7 min and 53 min, respectively. Similar to the effect of calcination temperature the overlong calcination time would lead to an aggregation of active Co_3O_4 and reduce exposed active sites, thus exhibit a poor H_2S removal efficiency. The saturated H_2S capacity and desulfurization rate of adsorbents exhibited the similar trends, which shows the maximum saturated H_2S capacity and desulfurization rate of 38.7 and 45.1%, respectively, at calcination time of 3 h.

3.2.3 Effect of adsorption conditions. The $Co_3O_4/MCM-41-U$ was prepared using $Co(NO_3)_2$ concentration of 10%, ultrasonic time of 2 h, calcination temperature of 550 °C and calcination time of 3 h. The effect of adsorption time on performance of H_2S removal of $Co_3O_4/MCM-41-U$ was evaluated at model gas flowrate of 20 mL min^{-1} in the fixed-bed reactor using 0.2 g of adsorbent (Fig. 11). With increasing the adsorption temperature, the breakthrough and saturated adsorption time both increased first and then decreased, reached the maximum at adsorption temperature of 45 °C (10 min). The breakthrough time at different adsorption temperatures was decreased in the order of 45 °C > 35 °C > 25 °C > 55 °C > 65 °C. This is because at excessive low adsorption temperature, the

H_2S adsorbed onto adsorbent mainly *via* weak van der Waals force by physical adsorption, which is usually reversible without selectivity. With increasing the adsorption temperature, the system temperature is able to provide enough energy to activate H_2S molecules, and the chemical adsorption *via* the strong

Fig. 12 H_2S breakthrough curves (a) and saturation sulfur capacity and desulfurization rate (b) of $Co_3O_4/MCM-41-U$ at different gas flowrates.

chemical bond gradually became the predominant adsorption mode. As a result, a much improved H₂S removal efficiency was observed. The saturated H₂S capacity and desulfurization rate of adsorbents exhibited the similar trends, which shows the maximum saturated H₂S capacity and desulfurization rate of 52.6 and 47.8%, respectively, at adsorption temperature of 45 °C.

The effect of model gas flowrate on performance of H₂S removal over Co₃O₄/MCM-41-U is evaluated at adsorption temperature of 45 °C in the fixed-bed reactor using 0.2 g of adsorbent (Fig. 12). With increasing the model gas flowrate, the breakthrough and saturated adsorption time both decreased, showing that increasing the gas flowrate would decrease the H₂S removal efficiency. This is understandable because the increase of gas flowrate, can eliminate the influence of external diffusion, but reduces the residence time of H₂S molecules in the fixed bed, which could cause some of the H₂S molecules are taken away by the rapid flow before they are adsorbed onto adsorbent. In other words, the contact between H₂S molecules and adsorbent is inadequate, as a result, a decrease in the breakthrough and saturated adsorption time H₂S removal efficiency with increasing gas flowrate was observed. Therefore, appropriate gas flowrate is beneficial to H₂S purification. The saturated H₂S capacity and desulfurization rate of adsorbents exhibited the similar trends, which shows the maximum saturated H₂S capacity and desulfurization rate of 52.6 and 47.8%, respectively, at gas flowrate of 20 mL min⁻¹. The breakthrough time (τ_a) and saturated adsorption time (τ_s) were 10 min and 50 min at gas flowrate of 20 mL min⁻¹. It can be calculated by eqn (3) that for this situation, the mass transfer zone (MTZ) of Co₃O₄/MCM-41-U is about 240 mm.

3.2.4 Adsorption mechanism. Watanabe *et al.*⁴ proposed that at ambient temperature H₂S removal from natural gas underwent through weak chemisorption over the activated carbon and zeolite/molecular sieve, while for metal oxides, such as ZnO, CuO, and Fe₂O₃, underwent through a dissociative chemisorption. Based on the reported adsorption mechanisms^{44,45} and our previous study,⁴⁶ a possible mechanism of H₂S removal over Co₃O₄/MCM-41-U adsorbent can be described by the following steps (Scheme 4): (1) H₂S molecules are adsorbed over Co₃O₄/MCM-41-U surface. (2) Dissociation of H₂S into H⁺ and HS⁻ or S²⁻ on Co₃O₄ active sites (eqn (5) and (6)); (3) subsequently sulfidation of the active Co₃O₄ by HS⁻ or S²⁻ leads

Scheme 4 Possible mechanism for the H₂S removal over Co₃O₄/MCM-41-U.

Table 2 Relation between regeneration times and desulfurization performance of Co₃O₄/MCM-41-U

Regeneration times	0	1	2
Breakthrough time (min)	10.0	9.6	9.1
Saturated H ₂ S capacity (mg g ⁻¹)	52.6	47.8	42.1
H ₂ S removal rate (%)	47.8	46.3	42.1

to the formation of cobalt sulfide and water at the surface of adsorbent (eqn (7) and (8)).

Formation of cobalt sulfide at the surface layers incorporating eqn (7) and (8)

3.2.5 Regeneration studies. Regeneration was performed *in situ*. Typically, the fixed-bed reactor with deactivated Co₃O₄/MCM-41-U was purged in a flowing nitrogen gas at 200 °C for 3 h and then cool down to the adsorption temperature. Relation between regeneration times and desulfurization performance of Co₃O₄/MCM-41-U is shown in Table 2. The breakthrough time of Co₃O₄/MCM-41-U after 2 times of regeneration decreased from 10.0 min to 9.1 min, which recovered by 91.0%. The recovered saturated H₂S capacity of Co₃O₄/MCM-41-U after 2 times of regeneration was 42.1 mg g⁻¹, still much higher than that of MCM-41, showing that the Co₃O₄/MCM-41-U possessed a good regenerability performance.

4 Conclusions

The Co₃O₄/MCM-41 adsorbents were successfully prepared by UAI and TMI technologies. XRD result demonstrated that UAI method promotes more and well defined highly dispersed active Co₃O₄ phase on MCM-41. All the adsorbents retained the mesoporous nature of MCM-41 with average pore diameter ranged in 2.75 to 374 nm after loading of Co₃O₄. The Co₃O₄/MCM-41-U which prepared *via* UAI method possessed much higher BET specific surface area and pore volume than those of Co₃O₄/MCM-41-T which prepared *via* TMI method. The fixed-bed adsorption desulfurization experiments showed H₂S removal was improved by loading Co₃O₄, showing that supporting active metal oxide on MCM-41 porous materials can take full advantages of metal oxides and MCM-41. The desulfurization performances decreased in the order of Co₃O₄/MCM-41-U > Co₃O₄/MCM-41-T > MCM-41. The Co₃O₄/MCM-41-U

prepared using $\text{Co}(\text{NO}_3)_2$ concentration of 10%, ultrasonic time of 2 h, calcination temperature of 550 °C and calcination time of 3 h exhibited the best H_2S removal efficiency. At adsorption temperature of 25 °C with model gas flowrate of 20 mL min^{-1} , the breakthrough time of $\text{Co}_3\text{O}_4/\text{MCM-41-U}$ was 10 min, and the saturated H_2S capacity and H_2S removal rate were 52.6 mg g^{-1} and 47.8%, respectively.
