## Mg–Ni–La based small hydrogen storage tank: kinetics, reversibility and reaction mechanisms

Palmarin Dansirima,<sup>a</sup> Lappawat Ngamwongwan,<sup>b</sup> Suwit Suthirakun,<sup>b</sup> Oliver Utke<sup>d</sup> and Rapee Utke<sup>a</sup>

The improvement of de/rehydrogenation kinetics and reversibility of a Mg–Ni–La based small hydrogen storage tank by doping with  $TiF_4$  and MWCNTs is reported for the first time. During sample preparation,  $MgH_2$  milled with 20 wt%  $LaNi_5$  and 5 wt%  $TiF_4$  and MWCNTs produces  $Mg_2NiH_4$  and  $LaH_3$ . Two-step dehydrogenation of  $Mg_2NiH_4$  and  $MgH_2$  is detected at 295 and 350 °C, respectively. Hydrogen desorption and absorption of the tank complete within 150 and 16 min, respectively, together with reversible hydrogen storage capacity up to 4.00 wt%  $H_2$  (68% of theoretical value) upon 16 de/rehydrogenation cycles. Heat release from exothermic hydrogenation is removed effectively at the end of a double tube heat exchanger, where the reaction heat and heat transfer fluid are first in contact. Co-catalytic effects of  $Mg_2NiH_4$  and  $LaH_3$  as well as good hydrogen diffusion benefit dehydrogenation kinetics and reversibility of the tank.

### Introduction

Due to its low cost, good reversibility, and high gravimetric storage capacity (7.6 wt%  $H_2$ ),  $MgH_2$  has been considered as one of the promising candidates for storing hydrogen.<sup>1,2</sup> However, high thermodynamic stability ( $\Delta H = 75 \text{ kJ mol}^{-1} H_2$ ) and poor hydrogen sorption kinetics (high desorption activation energy,  $E_A \sim 160 \text{ kJ mol}^{-1}$ ), leading to high desorption temperature ( $T_{des} \geq 400 \text{ }^\circ\text{C}$ ) obstruct its practical uses.<sup>2–6</sup> Thermodynamic destabilization of  $MgH_2$  by forming solid solutions with other metals, such as,  $Mg_2Ni$ ,  $Mg_2In_{0.1}Ni$ ,<sup>7</sup>  $Mg_{90}Ag_{7.5}Zn_{2.5}$ ,<sup>8</sup>  $Mg$ (In) doped with Al and Ti ( $Mg_{85}In_5Al_5Ti_5$ )<sup>6</sup> and  $MgF_2$  (ref. 9) have been reported. These solid solutions showed not only significant reduction of dehydrogenation enthalpies to 64.5–68.1  $\text{kJ mol}^{-1} H_2$  but also kinetic improvement.<sup>6,7,9</sup> Another promising approach to improve hydrogen sorption kinetics of  $MgH_2$  is addition of several catalysts and additives, including transition metals, halides, and oxides as well as intermetallic and ternary alkaline compounds.<sup>10–20</sup> New active species of metallic hydrides, such as  $TiH_2$ ,  $CeH_2$ , and  $KH$  formed upon cycling of  $MgH_2$  doped with  $TiF_3$ ,<sup>15</sup>  $CeO_2$ ,<sup>21</sup> and  $K_2NbF_7$ ,<sup>22</sup> respectively, favoured kinetic properties. Besides catalysts and additives in the form of fine particles, Fe nanosheets dispersed

in  $MgH_2$  matrices weakened Mg–H bond and provided active sites for hydrogen sorption, leading to significant reduction of onset desorption temperature and  $E_A$  by 168 °C and 85  $\text{kJ mol}^{-1}$ , respectively.<sup>16</sup>

Among several catalysts and additives, Ni considerably enhanced kinetic properties of  $MgH_2$  by weakening Mg–H bond and encouraging the recombination of H atoms during desorption.<sup>23,24</sup> For example,  $E_A$  and desorption temperature of  $MgH_2$  reduced by 110  $\text{kJ mol}^{-1}$  and 140 °C, respectively, after doping with 25 wt% Ni.<sup>24</sup> In addition, hydrogen sorption of Mg or  $MgH_2$  doped with 10–30 wt% of  $LaNi_5$  have been widely investigated.<sup>25–27</sup> Considering  $MgH_2$ – $LaNi_5$  composite prepared by either milling  $MgH_2$  with  $LaNi_5$  or hydrogenation of milled  $Mg$ – $LaNi_5$ , mixed phases of  $MgH_2$ ,  $Mg_2NiH_4$ , and  $LaH_3$  were formed, which  $Mg_2NiH_4$  and  $LaH_3$  played catalytic roles on hydrogen storage properties of  $MgH_2$ .<sup>27–29</sup>  $Mg_2NiH_4$  acted as nucleation sites for  $MgH_2$  formation, promoting hydrogenation of Mg,<sup>30</sup> while  $LaH_3$  decreased de/rehydrogenation enthalpy of  $MgH_2$ .<sup>28</sup> Hydrogen sorption kinetics of Mg–Ni–La composites could be enhanced by not only the sample preparation with fine and nanosized particles but also the suitable composition of mixed hydrides ( $MgH_2$ ,  $Mg_2NiH_4$ , and  $LaH_3$ ).<sup>25,26,31</sup> The best de/rehydrogenation kinetics (up to 3.5 wt%  $H_2$  released within 30 min) was obtained from  $MgH_2$  doped with 1.5 mol%  $LaNi_5$ .<sup>26</sup> Although hydrogen capacity of  $MgH_2$ –1.5 mol%  $LaNi_5$  composite reduced with respect to the theoretical capacity of  $MgH_2$  (from 7.6 to ~3.5 wt%  $H_2$ ) due to the formation of  $Mg_2NiH_4$  and thermodynamic stability of  $LaH_3$ , dehydrogenation temperature significantly decreased from 450 °C (as-received  $MgH_2$ ) to 350 and ~250 °C for  $MgH_2$  and  $Mg_2NiH_4$ , respectively.<sup>26</sup> Besides, several carbon based materials, such as

carbon nanofiber (CNF), expanded natural graphite (ENG), multi-walled carbon nanotubes (MWCNTs), and graphene have been proposed for kinetic improvement of  $\text{MgH}_2$ .<sup>32–34</sup> By doping with these carbon materials, many advantages of (i) enhancement of thermal conductivity and hydrogen diffusion (ENG),<sup>33</sup> (ii) suppression of hydride agglomeration upon cycling (MWCNTs, CNF, and graphene),<sup>32,34</sup> and (iii) catalytic effects of metallic impurities, *e.g.*, Fe and Ni obtained from the preparation processes (MWCNT and CNF)<sup>32</sup> benefit kinetics of hydride materials in both laboratory and tank scales.

In this work, de/rehydrogenation performances of Mg–Ni–La composite in the scale of a small hydrogen storage tank is reported for the first time. Mg–Ni–La composite is prepared by milling  $\text{MgH}_2$  with 20 wt%  $\text{LaNi}_5$  (~1.2 mol%), approaching to the most suitable  $\text{LaNi}_5$  content in  $\text{MgH}_2$ – $\text{LaNi}_5$  composite for the kinetic improvement (1.5 mol%).<sup>26</sup> Kinetics and reversibility of Mg–Ni–La based tank are improved by doping with  $\text{TiF}_4$  and MWCNTs. Transition metal-based catalysts ( $\text{TiF}_4$ ) favour kinetic properties. MWCNTs are expected to not only benefit kinetic properties due to metallic impurities and prevent particle growth upon cycling but also improve hydrogen diffusion inside hydride-based tank. Moreover, due to low cost and possibility for high quantity production, MWCNTs are suitable material for enhancing sorption kinetics of Mg–Ni–La composite in the tank scale. De/rehydrogenation kinetics and reversibility as well as the reaction mechanisms during hydrogen exchange reaction inside the storage tank are investigated. Chemical compositions and morphology of the samples at the initial state and after cycling are also studied.

## Experimental

$\text{MgH}_2$  doped with 5 wt%  $\text{TiF}_4$  and multi-walled carbon nanotubes (MWCNTs), denoted as  $\text{MgH}_2$ – $\text{TiF}_4$ –CNTs, was prepared by the procedures described elsewhere.<sup>20</sup> Mg powder ( $\geq 99.0\%$ , Aldrich) was hydrogenated at 320 °C under 15–20 bar  $\text{H}_2$  for 12 h to obtain as-prepared  $\text{MgH}_2$ . As-received  $\text{TiF}_4$  (99%, Acros Organics) and as-prepared  $\text{MgH}_2$  were milled for 3 and 5 h, respectively. MWCNTs (Nano Generation Co., Ltd. Thailand) were treated at 500 °C under vacuum for 3 h. As-prepared  $\text{MgH}_2$  was doped with 5 wt% of as-milled  $\text{TiF}_4$  and treated MWCNTs by ball milling for 30 min to achieve  $\text{MgH}_2$ –5 wt%  $\text{TiF}_4$ –5 wt% MWCNTs, denoted as  $\text{MgH}_2$ – $\text{TiF}_4$ –CNTs.  $\text{LaNi}_5$  (20 wt%) (hydrogen storage grade, Aldrich) was doped into  $\text{MgH}_2$ – $\text{TiF}_4$ –CNTs by ball milling for 30 min to obtain the composite, denoted as as-milled  $\text{MgH}_2$ –Ni–La@ $\text{TiF}_4$ –CNT. Ball milling for the preparation of all samples was carried out using a QM0.4L Planetary Ball Mill, Nanjing Chishun Science & Technology. The vial and balls (10 mm diameter) made from stainless steel (SS304) were employed. A ball-to-powder weight ratio (BPR) of 10 : 1 and the rotational speed of 580 rpm were applied for the preparation of all samples.

Chemical compositions were investigated by powder X-ray diffraction (PXD) using a Bruker D2 PHASER with  $\text{Cu K}\alpha$  radiation ( $\lambda = 1.5406 \text{ \AA}$ ). The sample was loaded into the sample holder covered with a poly(methyl methacrylate) (PMMA) dome under  $\text{N}_2$  atmosphere in the glove box. The diffractions were

observed in  $2\theta$  range and scanning steps of 10–80° and 0.02°  $\text{s}^{-1}$ , respectively. Dehydrogenation patterns and hydrogen content released were evaluated by hydrogen temperature-programmed desorption ( $\text{H}_2$ -TPD) technique using a Chemisorption Analyzer, BELCAT-B, BEL-Japan. The sample (~50.00 mg) was heated to 500 °C (5 °C  $\text{min}^{-1}$ ) under Ar flow of 30 mL  $\text{min}^{-1}$ . Quantitative analyses were characterized by using a conversion factor (CF, counts per mmol), the relation between TPD peak area and hydrogen amount desorbed.<sup>35,36</sup> Scanning electron microscopy (SEM) was performed by using a JSM-6010LV from JEOL. The sample was mounted onto the holder by using carbon tape and coated with an electron conductive element (Au).

A cylindrical hydrogen storage tank (packing volume of 96.2 mL) with the components shown in Fig. 1(A) was packed with 44.7248 g of as-milled  $\text{MgH}_2$ –Ni–La@ $\text{TiF}_4$ –CNT.<sup>37,38</sup> Temperature profiles during hydrogen exchange reaction were detected by K-type thermocouples (TCs, –250 to 1300 °C, SL heater) placed along the tank length (TC1, TC3, and TC4) (Fig. 1(B)). Setting temperature ( $T_{\text{set}}$ ) during the experiments was controlled by a PID temperature controller connected to TC2 as a temperature sensor for the controller. Hydrogen diffusion in the tank was enhanced by inserting four porous stainless steel (SS) tubes (SS304, no. 120) into the powder sample (Fig. 1(A) and (C)). De/rehydrogenation were performed using a test station integrated with a controller program constructed by

Fig. 1 The components of the cylindrical hydrogen storage tank (A) and the positions of thermocouples (TCs) inside the tank (B and C).

a LabVIEW® software.<sup>37–39</sup> System pressures were measured by pressure transducers using an OMEGA Engineering PX409-1.5KGI and PX309-3KGI. Temperature and pressure signals detected during the experiments were collected using the module data loggers (NI USB-6009, National Instruments). As-milled  $\text{MgH}_2$ –Ni–La@TiF<sub>4</sub>–CNT was hydrogenated at 250 °C under 10–15 bar H<sub>2</sub> to obtain as-prepared  $\text{MgH}_2$ –Ni–La@TiF<sub>4</sub>–CNT. Hydrogenation was carried out at isothermal condition ( $T_{\text{set}} = 250$  °C) under 10–18 bar H<sub>2</sub> and dehydrogenation was at  $T_{\text{set}} = 300$  °C with the initial pressure of ~15 bar H<sub>2</sub>, remaining after hydrogenation. Heat released during exothermic hydrogenation was removed by a double tube heat exchanger filled with 3–5 L min<sup>−1</sup> compressed air at room temperature. Prior to the titration measurements, 14 de/rehydrogenation cycles of as-prepared  $\text{MgH}_2$ –Ni–La@TiF<sub>4</sub>–CNT based tank were performed to stabilize the kinetics of hydride materials. Hydrogen desorbed content (standard L, SL) was measured using mass flow controller (MFC, 0–2 SL per min (SLM), a Bronkhorst EL-FLOW selected F-201CV) and calculated by integrating the peak area of hydrogen flow rate (SLM) *versus* time (min) plot. Total hydrogen storage capacity defined as the combination of remained hydrogen after absorption and material capacity was calculated as follows.

$$V_{\text{STP}} = \frac{P_s V_s T_{\text{STP}}}{T_s P_{\text{STP}}} \quad (1)$$

$$n_{\text{H}_2} = \frac{V_{\text{STP}}}{22.4 \text{ L mol}^{-1}} \quad (2)$$

$$\text{H}_2 \text{ capacity (wt\%)} = \frac{n_{\text{H}_2} \times 2.016 \text{ g mol}^{-1}}{\text{sample weight}} \times 100 \quad (3)$$

where  $V_{\text{STP}}$  (L) and  $V_s$  (SL) are volumes of hydrogen gas at the standard temperature and pressure condition (STP,  $T_{\text{STP}} = 273.15$  K and  $P_{\text{STP}} = 1.0133$  bar) and at the standard condition of MFC ( $T_s = 294.15$  K and  $P_s = 1.0085$  bar), respectively.  $n_{\text{H}_2}$  (mol) is hydrogen moles and standard molar volume is 22.4 L mol<sup>−1</sup>.

## Results and discussion

Chemical compositions of as-milled and as-prepared  $\text{MgH}_2$ –Ni–La@TiF<sub>4</sub>–CNT are investigated by PXD technique. From Fig. 2(A), diffraction peaks of  $\text{MgH}_2$ ,  $\text{LaNi}_5$ , and  $\text{MgO}$  are found in as-milled and as-prepared samples at all positions in the tank. The as-milled sample reveals a slight signal of Mg due to incomplete hydrogenation during sample preparation. All as-prepared samples show complete transformation of Mg to  $\text{MgH}_2$  (Fig. 2(A)). The formation of  $\text{MgO}$  is due to the oxidation of Mg-containing phases with air and moisture during the measurements. Slight signal of  $\text{LaH}_3$  detected in all as-prepared samples suggests the reaction of  $\text{LaNi}_5$ ,  $\text{MgH}_2$ , and H<sub>2</sub> to form  $\text{Mg}_2\text{NiH}_4$  and  $\text{LaH}_3$ .<sup>40</sup> Considering  $\text{LaNi}_5$  content (20 wt% or ~1.2 mol% with respect to  $\text{MgH}_2$  content), hydrogenation of Mg–Ni–La composite is represented stoichiometrically in eqn (4). The disappearance of  $\text{Mg}_2\text{NiH}_4$  diffraction in Fig. 2(A) can be due to a small amount, amorphous state, and/or

Fig. 2 PXD spectra of as-milled and as-prepared  $\text{MgH}_2$ –Ni–La@TiF<sub>4</sub>–CNT at different positions inside the tank (A) and H<sub>2</sub>-TPD results during dehydrogenation of as-received  $\text{MgH}_2$  and as-prepared  $\text{MgH}_2$ –Ni–La@TiF<sub>4</sub>–CNT (B).

inhomogeneity. Furthermore, dehydrogenation patterns of pristine  $\text{MgH}_2$  and as-prepared  $\text{MgH}_2$ –Ni–La@TiF<sub>4</sub>–CNT at TC1, TC3, and TC4 are investigated by H<sub>2</sub>-TPD technique. From Fig. 2(B), pristine  $\text{MgH}_2$  shows single-step dehydrogenation at onset and main temperatures at ~415 and 423 °C, respectively, together with hydrogen capacity of 4.81 wt% H<sub>2</sub>. For as-prepared  $\text{MgH}_2$ –Ni–La@TiF<sub>4</sub>–CNT samples, two-step decomposition of  $\text{Mg}_2\text{NiH}_4$  and  $\text{MgH}_2$  (eqn (5) and (6), respectively) are observed. Onset and main dehydrogenations of  $\text{Mg}_2\text{NiH}_4$  are found at 225 and 295–300 °C, respectively,<sup>26,29</sup> while those of  $\text{MgH}_2$  are at higher temperatures of 310 and 350–368 °C, respectively. Comparing with pristine  $\text{MgH}_2$ , onset and main dehydrogenation temperatures of  $\text{MgH}_2$  in as-prepared  $\text{MgH}_2$ –Ni–La@TiF<sub>4</sub>–CNT are significantly lower ( $\Delta T = 105$  and 75 °C, respectively). This can be explained by the catalytic effects of TiF<sub>4</sub>, MWCNTs, and the combined  $\text{Mg}_2\text{NiH}_4$ – $\text{LaH}_3$  on hydrogen sorption properties of  $\text{MgH}_2$ .<sup>27–29</sup> For phase transition of  $\text{LaH}_3$  to  $\text{LaH}_{2.3}$  at about 400 °C,<sup>26</sup> hydrogen signal cannot be observed by H<sub>2</sub>-TPD probably due to a small amount of  $\text{LaH}_3$ , corresponding PXD results (Fig. 2(A)). Hydrogen storage capacities in the range

of 3.60–3.68 wt% H<sub>2</sub> are obtained. Regarding the content of all components (MgH<sub>2</sub> doped with 20 wt% LaNi<sub>5</sub>, 5 wt% TiF<sub>4</sub>, and 5 wt% MWCNTs) and dehydrogenation pathways (eqn (5) and (6)), theoretical hydrogen storage capacity of 5.9 wt% H<sub>2</sub> is calculated according to eqn (7). Deficient hydrogen content detected from H<sub>2</sub>-TPD results (Fig. 2(B)) with respect to theoretical capacity is described by an incomplete reaction between LaNi<sub>5</sub> and MgH<sub>2</sub> to form Mg<sub>2</sub>NiH<sub>4</sub> during sample preparation (eqn (4)), confirmed by the signal of residual LaNi<sub>5</sub> in PXD spectra of as-prepared samples (Fig. 2(A)).

Theoretical H<sub>2</sub> capacity (wt% H<sub>2</sub>)

$$= \frac{\text{H}_2 \text{ mass}}{\text{mass of } (\text{MgH}_2 + \text{LaNi}_5 + \text{TiF}_4 + \text{MWCNTs})} \times 100 \quad (7)$$

Comparing with MgH<sub>2</sub>–TiF<sub>4</sub>–MWCNTs based tank reported in the previous work,<sup>37</sup> the dehydrogenation temperature of MgH<sub>2</sub> reduces from 388 to 350–368 °C (MgH<sub>2</sub>–Ni–La@TiF<sub>4</sub>–CNT tank in this work). Moreover, significant Mg<sub>2</sub>NiH<sub>4</sub> content (and also LaH<sub>3</sub>) at TC3 > TC4 > TC1, assured by the greater area of the first H<sub>2</sub>-TPD peak in Fig. 2(B) results in lower dehydrogenation temperature and faster kinetics of MgH<sub>2</sub>. This might be attributed to the catalytic effects of *in situ* formed LaH<sub>3</sub> and Mg<sub>2</sub>NiH<sub>4</sub> on kinetic properties of MgH<sub>2</sub>.<sup>26</sup> Besides, it was reported that LaH<sub>3</sub> could decrease dehydrogenation enthalpy of MgH<sub>2</sub>,<sup>28</sup> while Mg<sub>2</sub>NiH<sub>4</sub> acted as nucleation sites for MgH<sub>2</sub> formation.<sup>30</sup> Different amounts of Mg<sub>2</sub>NiH<sub>4</sub> at TC1, TC3, and TC4 can be described by poor distribution of LaNi<sub>5</sub> in MgH<sub>2</sub> matrices and/or ineffective hydrogenation due to deficient heat exchange between exothermic hydrogenation and heat transfer fluid.

De/rehydrogenation kinetics, reversibility, and reaction pathways of MgH<sub>2</sub>–Ni–La@TiF<sub>4</sub>–CNT based tank are further studied. Prior to cycling, MgH<sub>2</sub>–Ni–La@TiF<sub>4</sub>–CNT based tank was stabilized by performing 14 de/rehydrogenation cycles. The first dehydrogenation at isothermal condition ( $T_{\text{set}} = 300$  °C) under the initial pressure of 15 bar H<sub>2</sub>, remaining after absorption is carried out by releasing hydrogen through MFC with a constant flow rate of 0.3 SLM (Fig. 3(A)). Endothermic dehydrogenation starts at  $t \sim 6$  min under system pressure ( $P_{\text{sys}}$ ) of 3.5 bar H<sub>2</sub>. Two-step decomposition of Mg<sub>2</sub>NiH<sub>4</sub> and MgH<sub>2</sub>, in accordance with H<sub>2</sub>-TPD results of as-prepared samples (Fig. 2(B)) is observed at equilibrium temperatures ( $T_{\text{eq}}$ ) of 290–307 and 290–300 °C, respectively. These  $T_{\text{eq}}$  are in accordance with equilibrium pressure ( $P_{\text{eq}}$ ) of ~2.5–4 and ~1.3–1.8 bar H<sub>2</sub> for Mg<sub>2</sub>NiH<sub>4</sub> and MgH<sub>2</sub>, respectively.<sup>40,41</sup> The greater  $P_{\text{eq}}$  than  $P_{\text{sys}}$  (1.9–2.4 and 1.1 bar H<sub>2</sub> for Mg<sub>2</sub>NiH<sub>4</sub> and MgH<sub>2</sub>, respectively) (Fig. 3(A)) encourages dehydrogenation of hydride materials, confirmed by continuous hydrogen release and endothermic event at all positions in the tank. Significant endothermic desorption at TC3 and TC4 revealed as considerable

Fig. 3 Temperature, pressure, and mass flow rate signals during dehydrogenation ( $T_{\text{set}} = 300$  °C) (A) and rehydrogenation ( $T_{\text{set}} = 250$  °C and  $P(\text{H}_2) = 10\text{--}18$  bar) (B) of MgH<sub>2</sub>–Ni–La@TiF<sub>4</sub>–CNT based tank.

temperature reduction ( $\Delta T = 20\text{--}25$  and  $22\text{--}30$  °C for the decomposition of Mg<sub>2</sub>NiH<sub>4</sub> and MgH<sub>2</sub>, respectively) and long plateau range suggest effective dehydrogenation. This can be due to the greater amount of Mg<sub>2</sub>NiH<sub>4</sub> (and also LaH<sub>3</sub>) formed at TC3 and TC4, corresponding to H<sub>2</sub>-TPD results (Fig. 2(B)). Moreover, effective heat supply from the external heater at the middle position of the tank (TC3) shown as the highest initial temperature ( $T_{\text{in}} = 320$  °C) favours desorption kinetics. For TC4, although  $T_{\text{in}}$  is lower (312 °C), the position adjacent to hydrogen inlet and outlet possibly benefits hydrogen release from the tank and also desorption kinetics. Hydrogen flow rate of 0.3 SLM is continuously obtained for 21 min and gradually decreases until dehydrogenation completes at  $t = 150$  min, in accordance with the increase of temperatures at all TCs to the initial values.

Total hydrogen content and storage capacity are 21.00 SL and 3.90 wt% H<sub>2</sub>, respectively (Fig. 3(A)). By subtracting with hydrogen content remaining after hydrogenation (1.10 SL and ~0.20 wt% H<sub>2</sub>), the material storage capacity of MgH<sub>2</sub>–Ni–La@TiF<sub>4</sub>–CNT based tank is 3.70 wt% H<sub>2</sub>, approaching to hydrogen content detected in H<sub>2</sub>-TPD results (Fig. 2(B)). Furthermore, rehydrogenation is continued at isothermal condition ( $T_{\text{set}} = 250$  °C) under  $P_{\text{sys}}$  of 10–18 bar H<sub>2</sub> with compressed airflow of 3–5 L min<sup>-1</sup> ( $T_{\text{air-in}} = 24$  °C) as heat

transfer fluid (Fig. 3(B)). Comparable  $T_{in}$  at all positions (251–258 °C) indicates good thermal conductivity in the tank achieved from addition of MWCNTs.<sup>20</sup> By applying hydrogen to the tank, all temperatures increase rapidly to  $T_{eq}$  of 365–383 °C owing to fast exothermic absorption (Fig. 3(B)). These  $T_{eq}$  are in agreement with  $P_{eq}$  of ~10–14 and 10–20 bar H<sub>2</sub> for MgH<sub>2</sub> and Mg<sub>2</sub>NiH<sub>4</sub>, respectively.<sup>41,42</sup> Comparable  $P_{eq}$  with  $P_{sys}$  implies superior hydrogen diffusion inside the tank during hydrogenation. This can be benefited by the insertion of porous SS tubes in the powder sample (Fig. 1(C)). The enhanced temperature of compressed air from 24 to 99 °C indicates effective heat transport from the exothermic hydrogenation to heat transfer fluid. Complete hydrogenation assured by temperature reduction to initial values at all positions is within 16 min (Fig. 3(B)). Comparing to the previous work of MgH<sub>2</sub>–TiF<sub>4</sub>–MWCNTs tank with comparable sample mass (~45 g),<sup>20</sup> hydrogen desorption and absorption times reduce from 200 and 40 min, respectively, to 150 and 16 min, respectively (MgH<sub>2</sub>–Ni–La@TiF<sub>4</sub>–CNT tank in this study). It should be noted that hydrogenation with short plateau range is found at both ends of the tank (TC1 and TC4), while that at the middle position (TC3) reveals longer plateau temperature (Fig. 3(B)). The short plateau range hints at either fast kinetics or ineffective hydrogenation. Considering the high Mg<sub>2</sub>NiH<sub>4</sub> content found at TC4 (H<sub>2</sub>-TPD curves and dehydrogenation profiles in Fig. 2(B) and 3(A), respectively), its short plateau temperature indicates fast and effective hydrogenation, whereas that at TC1 (low Mg<sub>2</sub>NiH<sub>4</sub> content) is most likely due to poor kinetics. Superior kinetics at TC4 might be explained by the fact that it is the first position, where the cold compressed air is in contact with the heat from the exothermic hydrogenation. However, reaction heat accumulated in the heat transfer fluid at TC3 and TC1 probably lead to reduced hydrogenation efficiency. Furthermore, cycling stability and effective reversibility of MgH<sub>2</sub>–Ni–La@TiF<sub>4</sub>–CNT based tank are revealed by the comparable total and material capacities of 3.89–4.00 and 3.67–3.77 wt% H<sub>2</sub>, respectively (up to 68 and 64% of theoretical

value, respectively) upon 16 de/rehydrogenation cycles (Fig. 4). Considering MgH<sub>2</sub> doped with 1.5 mol% LaNi<sub>5</sub> approaching to LaNi<sub>5</sub> content used in our work (1.2 mol%), hydrogen capacity up to 3.5 wt% H<sub>2</sub> was obtained from this Mg–Ni–La composite in the laboratory scale.<sup>26</sup> De/rehydrogenation performances and reversibility of hydride materials are usually deficient after upscaling due to poor thermal conductivity and hydrogen diffusion inside the hydride beds. However, greater material hydrogen capacities (3.67–3.77 wt% H<sub>2</sub>) of MgH<sub>2</sub>–Ni–La@TiF<sub>4</sub>–CNT based tank than that of MgH<sub>2</sub> doped with 1.5 mol% LaNi<sub>5</sub> (3.5 wt% H<sub>2</sub>) are observed and maintained upon cycling. This can be explained by catalytic effects and the enhanced thermal conductivity and hydrogen diffusion obtained after doping with TiF<sub>4</sub> and MWCNTs.

Furthermore, the reaction mechanisms during cycling at different positions inside the tank are characterized by PXD technique. To avoid interrupting the cycling measurements and due to comparable performances upon cycling, the de/rehydrogenated samples after the 16<sup>th</sup> cycles are collected for characterizations. From Fig. 5(A), comparable phases of Mg<sub>2</sub>Ni, Mg, LaH<sub>3</sub>, LaNi<sub>5</sub>, and MgO are found in dehydrogenated samples at all positions. The formation of Mg<sub>2</sub>Ni and Mg hints

at successful dehydrogenation of  $\text{Mg}_2\text{NiH}_4$  and  $\text{MgH}_2$  (eqn (5) and (6)), while the thermally stable phase of  $\text{LaH}_3$  does not decompose due to low operating temperature during dehydrogenation ( $T_{\text{set}} = 300$  °C). The signal of  $\text{LaNi}_5$  suggests the incomplete formation of  $\text{Mg}_2\text{NiH}_4$  (eqn (4)) during sample preparation. In the case of hydrogenation, all hydrogenated samples show diffraction peaks of  $\text{MgH}_2$ ,  $\text{Mg}_2\text{NiH}_4$ ,  $\text{LaH}_3$ ,  $\text{LaNi}_5$ ,  $\text{Mg}$ , and  $\text{MgO}$  (Fig. 5(B)). The formation of  $\text{MgH}_2$  and  $\text{Mg}_2\text{NiH}_4$  implies successful rehydrogenation of  $\text{Mg}$  and  $\text{Mg}_2\text{Ni}$ , respectively (reverse reaction of eqn (5) and (6)). The unreacted  $\text{LaNi}_5$  and  $\text{Mg}$  found upon cycling are responsible for deficient hydrogen released and reproduced to the theoretical capacity (5.9 wt%  $\text{H}_2$ ) (Fig. 4). Moreover, the morphology of the samples at as-prepared state and after cycling are investigated by SEM technique. Comparable morphology and various particle sizes in micrometer range are discovered in as-prepared samples at all positions (Fig. 6(A)). For the samples after cycling, finer powder with smaller particle size as compared with as-prepared samples are detected (Fig. 6(B)). This can be described by effective de/rehydrogenation upon cycling due to significant hydrogen diffusion in hydride beds inside the tank. Nevertheless, particle agglomeration partially found in the sample at TC1 (a red circle in Fig. 6(B)) suggests less effective hydrogen de/absorption, corresponding to  $\text{H}_2$ -TPD results and de/rehydrogenation profiles (Fig. 2(B) and 3).

## Conclusions

Kinetic properties, cycling efficiency, and reaction pathways of Mg–Ni–La based small hydrogen storage tank doped with  $\text{TiF}_4$  and MWNTs were investigated. During sample preparation,  $\text{MgH}_2$  reacted with  $\text{LaNi}_5$  and  $\text{H}_2$  to form  $\text{Mg}_2\text{NiH}_4$  and  $\text{LaH}_3$ . Onset and main decompositions of  $\text{Mg}_2\text{NiH}_4$  were found at 225 and 295–300 °C, respectively, while those of  $\text{MgH}_2$  were at 310 and 350–368 °C, respectively. Dehydrogenation kinetics at the

middle and hydrogen inlet/outlet positions was enhanced due to sufficient heat supplied from the external heater and fast hydrogen release from the tank. Superior hydrogen diffusion at all positions in the tank was confirmed by comparable applied pressure with equilibrium pressure. Hydrogenation performances relied on the effectiveness of heat transfer from exothermic reaction to heat transfer fluid. Fast hydrogenation kinetics was found at the hydrogen inlet/outlet position, where the heat transfer fluid was firstly in contact with reaction heat. Total and material hydrogen capacities upon 16 de/rehydrogenation cycles were averagely in the ranges of 3.89–4.00 and 3.67–3.77 wt%  $\text{H}_2$ , respectively. Due to good hydrogen diffusion inside the tank, effective de/rehydrogenation cycles were obtained and revealed as the powder sample with finer and smaller particles after cycling. However, partial particle agglomeration was found at the position with poor performances.
