An efficient 2-furyl gold–carbene promoted synthetic method was developed for the formation of dihydroquinazolinones from enynones by dual insertion of anthranilamides. In this organic transformation a new C–O and two C–N bond formations occurred and dihydroquinazolinones were obtained with a quaternary centre in moderate to very good yields in one-pot synthesis.

Introduction

Nitrogen-containing heterocyclic molecules¹ such as quinazolinones have gained much attention due to their wide range of biological and pharmacological applications.² Dihydroquinazolinone derivatives like fenquizon, and quinethazone⁴ are drugs for edema and hypertension. It was reported that bouchardatine exhibits antiobesity activity,⁵ and penipanol C exhibits tobacco mosaic virus inhibition⁶ (Fig. 1). Further, substituted dihydroquinazolinone derivatives displayed significant cytotoxic activity.⁷

Hence, the development of new synthetic methods for the formation of dihydroquinazolinones is a limitless frontier. Cooperative catalysis⁸ has been established as a handy tool for the synthesis of several biologically valuable molecules and different procedures were reported for the synthesis of dihydroquinazolinone derivatives.⁹ Exploration of gold-catalyzed¹⁰ organic transformations has attracted much attention in recent years due to their broad functional group tolerance and selectivity for the formation of valuable heterocyclic molecules in one-pot reaction conditions.¹¹ The recent literature indicating that exploitation of enynal/enynone has recognised as good donor or donor–donor carbene precursors for C–H/X–H insertion and cyclopropanation reactions.¹² Several reports are available for synthesis of substituted furans from enynones in presence of metal catalysts *via* a 5-*exo*-dig cyclization.¹³

The reaction mechanism was proposed *via* (2-furyl) metal-carbene¹⁴ intermediate would react with one nucleophile¹⁵ to produce addition products (Scheme 1, eqn (1)). López and Vicente co-workers reported a method for synthesis of functionalized furans from enynones in the presence of zinc catalyst.¹⁶ Recently, Zhu *et al.* developed metal carbene promoted method for synthesis of vinyl-substituted dihydroindoles.¹⁷ Hashmi and co-workers studied the stabilization effects of gold carbene complexes.¹⁸

Double insertion of isocyanides to enynones produced pyrrole-fused heterocyclic molecules *via* (2-furyl) metal-carbene

intermediate was reported by Jia and Li co-workers (Scheme 1, eqn (2)).¹⁹ Very recently, we have reported formation of tetraarylmethane derivatives by reaction of enynones with indoles *via* (2-furyl) gold-carbene intermediate (Scheme 1, eqn (3)).²⁰ Our current research²¹ efforts focused to explore the reactivity of enynones under gold catalysis. We envisioned that reaction of enynones (**1**) in the presence of gold-catalyst would produce gold-carbene complex-I, which would react with anthranilamide (**2**) may give corresponding dihydroquinazolinone derivative **3** (Scheme 1, eqn (4)).

Results and discussion

Accordingly, we have conducted an experiment by using substrates **1a** and **2a** in the presence of AuCl₃ (Scheme 2). Very interestingly, 21% yield of the corresponding product 2-(4-benzoyl-5-phenylfuran-2-yl)-2-phenyl-2,3-dihydroquinazolin-4(1H)-one **3a** was observed. The product **3a** was further

^a Reaction conditions: all reactions were carried out at 80 °C under nitrogen atmosphere with **1** (1.0 equiv.), and **2a** (1.5 equiv.) in the presence of KAuCl₄ (10 mol%), FeCl₃ (2.0 equiv.) and solvent (3 mL) in oil bath; yields are for isolated products.

confirmed by single crystal X-ray analysis.²² It is noteworthy that in this organic transformation two C–N bonds were formed by dual insertion of anthranilamide with a quaternary centre. This interesting observation encouraged us to optimize this reaction to get the better yields of the product **3a**.

Gold(i) catalysts were screened with the substrates **1a** with **2a** to produce moderate yields of **3a** along with **3a'** (Table 1, entries 1 and 2). Whereas when experiments were conducted in the

presence of AuBr₃ and KAuCl₄ moderate yields of product **3a** was observed (Table 1, entries 3 and 4). Complex mixture was obtained while reaction was performed in the presence of IPrAuCl (Table 1, entry 5). In the presence of AuClPPh₃, poor yields of desired product **3a** was found (Table 1, entry 6). Then reactions were conducted by utilizing gold catalysts in combination of selectfluor (Table 1, entries 7–10), yields of desired product **3a** was not improved. Reactions were performed by employing KAuCl₄ in combination with K₂S₂O₈, CF₃COOH, Cu(OAc)₂, K₂CO₃, pyridine *N*-oxide and PhI(OAc)₂ (Table 1, entries 11–16), moderate yield of **3a** was observed. Nevertheless, KAuCl₄ and FeCl₃ combination afforded very good yield of (81%) of product **3a** (Table 1, entry 17). An experiment was conducted by utilizing only FeCl₃, poor yields of product **3a** was observed along with **3a'** (Table 1, entry 18). Reactions were screened by using series of solvents like toluene, MeOH, THF, DMF and DCE, none of them gave better yield than MeCN (Table 1, entries 19–23). When the gold-catalyst loading decreased from 10 mol% to 5 mol% and 7 mol%, the product yield also reduced to 52% and 58%, respectively (Table 1, entries 24 and 25). Two reactions were conducted without utilizing FeCl₃ and these cases poor yields of product **3a** observed (Table 1, entries 26 and 27).

The above experiments concludes that Table 1, entry 17 is the best suitable reaction conditions. Then substrate scope was tested by utilizing different enynones (**1a–k**) with anthranilamide **2a** under the optimal conditions. These results are incorporated in the Table 2.

The substrates which are bearing electron-donating groups such as **1b** and **1c** were tested with **2a** to provide 76% and 72% yields of corresponding products **3b** and **3c**, respectively. Electron-withdrawing functional group containing enynone such as **1d** react with **2a** to give the corresponding dihydroquinazolinone derivative **3d** in 68% yield. Substrates bearing electron-donating groups like **1e** and **1f** reacted with **2a** to produce 75% and 74% yields of the corresponding dihydroquinazolinone derivatives **3e** and **3f**, respectively. Both electron-donating and electron-withdrawing functional groups containing enynone like **1g** reacted with **2a** to generate the corresponding product **3g** in 71% yield. The substrates which are having electron-donating groups at *ortho* position of R² like **1h** (R² = 3-Me-C₆H₄), **1i** (R² = 3-Me-C₆H₄, R¹ = 4-Me-C₆H₄) and **1j** (R¹ = 3-Me-C₆H₄) reacted with **2a** to provide the corresponding products **3h**, **3i** and **3j** in moderate yields, respectively (Table 2, entries 8–10). Alkyl substitution at R² position containing substrate like **1k** produced the product **3k** in 43% yield (Table 2, entry 11).

Further, experiments were conducted to check the scope of dihydroquinazolinone derivatives by utilizing different substituted anthranilamides (**2b–e**) with enynones (**1a–f**). These results were included in the Table 3. The enynone **1a** was tested with electron-donating functional group containing anthranilamide **2b** to give **3l** in 72% yield. Electron-withdrawing functional group containing anthranilamides such as **2c**, **2d**, and **2e** reacted with **1a** to produce the corresponding dihydroquinazolinone derivatives **3m**, **3n**, and **3o** in 65%, 63% and 60% yields, respectively (Table 3, entries 2–4). Enynones bearing

electron donating groups such as **1b** and **1c** reacted with **2b** to provide corresponding products **3p** and **3q** in 72% and 70% yields, respectively (Table 3, entries 5 and 6). Fluorine substituted enynone such as **1d** reacted with **2b**, **2c**, **2d** and **2e** to provide the corresponding dihydroquinazolinone derivatives

such as **3r**, **3s**, **3t** and **3u** in 69%, 63%, 61% and 62% yields, respectively (Table 3, entries 7 and 10). Electron-donating substitutions containing enynones such as **1e** and **1f** reacted with **2b** under optimized reaction conditions to give the corresponding products **3v** and **3w** in 70% and 68% yields, respectively (Table 3, entries 11 and 12).

2-Amino-6-phenyl-4-(trifluoromethyl)nicotinamide **2f** reacted with **1a** to produce the corresponding product **3t** in 58% yield (Scheme 3, eqn (1)). An experiment was conducted by employing a phosphorus substituted enynone like **1l** with **2a** to provide the corresponding dihydroquinazolinone derivative **3y** in 68% yield (Scheme 3, eqn (2)). Further, one more experiment was conducted in gram scale by utilizing **1a** and **2a** under optimized reaction conditions to give the corresponding product **3a** in 74% yield (Scheme 3, eqn (3)).

Control experiments were conducted to clarify the reaction mechanism (Scheme 4). The substrate **1a** was tested under optimized conditions to produce good yields of product **3a'** (Scheme 4, eqn (1)). A reaction was conducted by utilizing **3a'** with anthranilamide **2a** in the presence of gold-catalyst to provide 32% yield of product **3a** (Scheme 4, eqn (2)). Without using catalyst one reaction was conducted by using **3a'** and **2a**,

in this case product **3a** was not observed (Scheme 4, eqn (3)). Then **1a** was tested with 2-(prop-2-yn-1-yloxy)benzohydrazide **4** to give 62% yield of product **5**. The structure of the compound **5a** further characterized by single crystal X-ray analysis.²²

Formation of dihydroquinazolinones can be proposed by the reaction mechanism as shown in Scheme 5. Gold catalyst would coordinate with enynone **1a** may form complex-A, which would further generate 2-furyl gold carbene complex-I *via* intramolecular of 5-*exo*-dig cyclised zwitterionic complex-B.²⁴ Then, it would produce ketone (**3a'**),^{13,14} which would coordinate with ferric chloride as a Lewis acid in a regioselective fashion then it would react with anthranilamide (**2a**) may generate IM-I. Subsequent activation of IM-I by metal catalyst may lead to cyclization to form intermediate IM-II, which would finally afford the product **3a**.

Conclusion

In conclusion, we have established gold-catalyzed reaction of enynones with dual insertion of anthranilamides to produce a novel approach for synthesis of dihydroquinazolinones. It is significant that in this organic transformation new C–O and two C–N bonds were formed with a quaternary centre with good functional group tolerance.

Experimental section

General information

Reactions were carried out in oven dried reaction flasks under nitrogen atmosphere and also solvents and reagents were transferred by oven-dried syringes to ambient temperature. TLC was performed on Merck silica gel aluminium sheets using UV as a visualizing agent. Solvents were removed under reduced pressure. Columns were packed as slurry of silica gel in hexane and ethyl acetate solvent mixture. The elution was assisted by applying pressure with an air pump. ¹³C NMR spectra were recorded on 75, 100 and 125 MHz spectrometers. ¹H NMR spectra were recorded on 300, 400 and 500 MHz spectrometers in appropriate solvents using TMS as internal standard. The following abbreviations were used to explain multiplicities: s = singlet, d = doublet, dd = double doublet, dt = doublet of triplet, td = triplet of doublet, t = triplet, m = multiplet, br s = broad singlet. All reactions were performed under nitrogen atmosphere with freshly distilled and dried solvents. All

solvents were distilled using standard procedures. Unless otherwise noted, reagents were obtained from Aldrich, Alfa Aesar, and TCI used without further purification. Synthesis of enynones (**1a–l**) were prepared by following reported procedures.²⁵

General procedure for synthesis of dihydroquinazolinone derivatives (**3a**)

To a 10 mL round-bottomed flask equipped with magnetic stir bar the substrate 2-aminobenzamide **2a** (0.45 mmol, 61 mg, 1.5 equiv.) was taken and dissolved in dry CH₃CN (3 mL) at 80 °C (oil bath) after that 1,3-diphenyl-2-(3-phenylprop-2-yn-1-ylidene) propane-1,3-dione **1a** (0.3 mmol, 100 mg, 1 equiv.) was added. To this reaction mixture KAuCl₄ (10 mol%, 11 mg) and FeCl₃ (0.6 mmol, 97 mg, 2.0 equiv.) was added and stirred at 80 °C for 5 h under nitrogen atmosphere. Progress of the reaction was monitored by using TLC. After completion of the reaction, the reaction mixture was filtered through celite plug and washed with ethyl acetate. The ethyl acetate layer was concentrated under reduced pressure to get crude residue which was purified by column chromatography through silica gel using hexane and ethyl acetate as eluent (10 : 3.5) to give 113 mg of the product 2-(4-benzoyl-5-phenylfuran-2-yl)-2-phenyl-2,3-dihydroquinazolin-4(1H)-one **3a** (81% yield). The same reaction was conducted on a gram scale by utilizing **1a** (1 g) and **2a** (0.61 g) produced the corresponding product **3a** in 74% yield (1.03 g). A similar experimental procedure was adopted for the synthesis of all the furan containing dihydroquinazolinones (**3b–y**) and **5**.
