Facile assembly of 1,5-diazocan-2-ones via cyclization of tethered sulfonamides to cyclopropenes†

 and Michael Rubin[†]  ^{*ac}

The sulfonamide moiety was evaluated as an activating and stabilizing functional group in the metal-templated strain release-driven intramolecular nucleophilic addition of amines to cyclopropenes to generate 1,5-diazocan-2-ones.

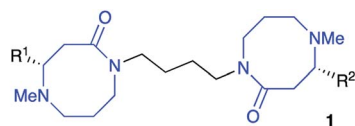

Introduction

Compounds containing the 1,5-diazocin-2-one moiety are scarce in nature,¹ with the best known examples occurring in the *Homalium* alkaloid family (1a–d, Fig. 1). The four known naturally-occurring *Homalium* alkaloids isolated from the leaves of *Homalium pronyense* Guillaum. are biogenically-derived from spermine and the appropriate α,β -unsaturated fatty or cinnamic

acids.^{1,2} These unique bis-azalactams have been the targets of a number of synthetic efforts over the past three decades.¹

The 1,5-diazocin-2-one core has recently been exploited in new therapeutic agents (Fig. 1). For example, diazocan peptomimetic BDBM50171126 (2) exhibits high levels of activity as a selective caspase-1 inhibitor. Compounds in this class has shown promising anti-inflammatory and analgesic activity in animal models for the treatment of rheumatoid arthritis.^{3,4} Compound SM-337 (3) belongs to a family of conformationally-constrained mimetics of the endogenous IAP antagonist Smac. Over the past decade, Smac mimetics have garnered increasing attention showing great potential as a new class of antitumor drugs.^{5,6}

It is known that medium-sized 8-membered rings are difficult to assemble *via* conventional methods of cyclization,⁷ largely due to the enthalpic cost incurred in the transition state as well as the decreased entropy of the cyclic products relative to their linear precursors.⁸ Several alternative synthetic approaches to the eight-membered 1,5-diazocin-2-one core have been developed, including Beckman rearrangement,⁹ fragmentation of 1,5-diazabicyclo[3.3.1]nonan-2-ones,¹⁰ reductive N–N scission of tetrahydro-1*H*,5*H*-pyrazolo[1,2-*a*]pyrazol-1-ones,^{11–14} as well as various ring closures, exploiting intramolecular versions of reductive amination,^{15–18} amine acylation,^{7,19–22} strain release-driven transamidation,^{23–25} and S_NAr reactions.²⁶ Herein, we disclose a new application of metal-templated intramolecular 8-*exo-trig* cyclization involving nucleophilic addition of sulfonamides tethered to a cyclopropene moiety.

Results and discussion

We have recently reported on the key role of potassium cations in the chelation-controlled cyclization of cyclopropenes 4 linked to nucleophilic alkoxide moieties.^{27–29} This innovative approach allows for a highly efficient and diastereoselective assembly of cyclic ethers 5 with ring sizes 7 to 10 (Scheme 1).^{27–29} These bicyclic structures produced new, highly selective anti-

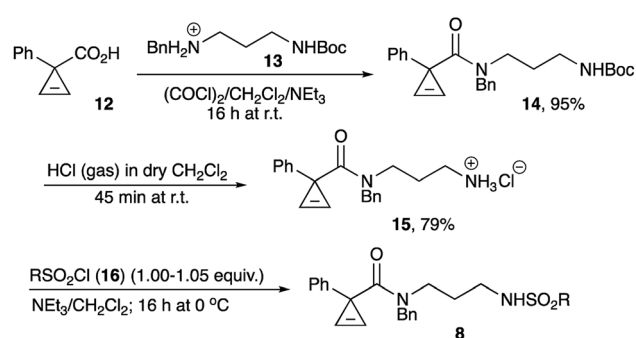

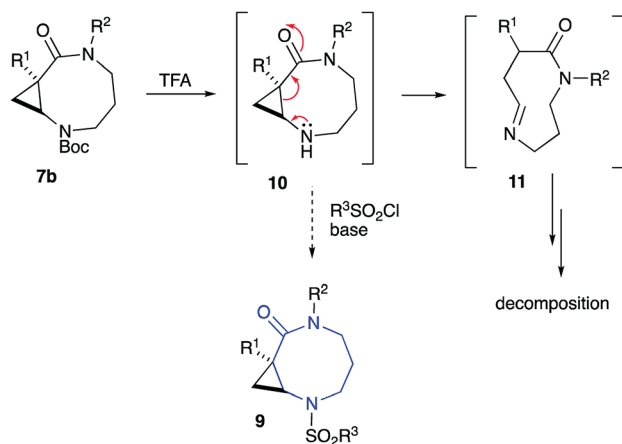

mycobacterial agents.²⁹ Closely related diazepinones and diazeanones **7** demonstrated antitumor activity. These species could be accessed *via* the potassium-templated cyclization of cyclopropenes **6** with tethered carbamates (Scheme 1).³⁰

In order to carry out more focused and complete SAR studies, we wanted to gain access to analogs within scaffold **7** by replacing the Boc protecting group with a range of substituents. This study is focused on the synthesis of sulfonamides **9**, which give rise to three points of diversity. It should be pointed out, that a scope of substituents R^1 and R^2 as well as ring size in such bicyclic scaffolds was already previously investigated.^{29,30} The current study is focused on evaluating the activating properties of different sulfonyl protecting groups. We also briefly examined the use of these sulfonamides as chiral auxiliaries.

The diversity-oriented approach to **9** was to rely on the late-stage functionalization of cyclic secondary amine **10**, which was to be accessible *via* simple acid-assisted deprotection of routinely available carbamates **7b** (Scheme 2). Removal of the Boc group moderating the electronic density at the N-2 resulted in intermediate cyclopropane **10** undergoing facile ring cleavage

and subsequent decomposition *via* cyclic imine **11** (Scheme 2). The intermolecular version of this small ring cleavage reaction allowed for the expeditious access of GABA amides.³¹ Based on the decomposition of **10** *via* **11** to other species, the access of sulfonamides **9**, ultimately required the installation of the sulfonyl group prior to the cyclization step.

Primary amine hydrochloride **15** was envisioned to serve as a common precursor to the linear sulfonamides series **8**. To this end, readily available cyclopropene-3-carboxylic acid **12**^{32,33} was employed in acylation of *tert*-butyl (3-(benzylamino)propyl) carbamate hydrochloride (**13**)³⁴ to afford amide **14**. The carbamate protecting group in the latter was removed *via* treatment with anhydrous HCl in dichloromethane to provide the desired salt **15** in good overall yield (Scheme 3). Next, the series of sulfonamides **8a-h** was prepared by treating **15** with the corresponding sulfonyl chlorides in the presence of base. These reactions proceeded uneventfully, affording moderate to good yields (Scheme 3). It should be pointed out that the signals of the two different rotamers present in NMR spectra of all amides **8** complicated spectral analysis. However, all these materials were chromatographically pure and perfectly suitable for further transformation. Subsequently, sulfonamides **8** were treated with freshly ground powdered KOH in anhydrous THF at 50 °C, as these reaction conditions were previously shown to be optimal for the cyclization of carbamates.³⁰ Gratifyingly, most of sulfonamides tested (**8a-f**) underwent the reaction smoothly affording the corresponding products **9a-f** in high yields. The reaction seems to be very tolerant to steric hindrance at the sulfonyl group. Indeed, only minor reduction in yield was observed in the formation of product **9c** bearing the bulky 2,5-xyllyl group. An attempt to employ sulfonamides bearing electron-withdrawing substituents revealed a somewhat more serious limitation of this methodology. As expected, the N-H bond in these sulfonamides is much more acidic, but the corresponding conjugate base is significantly less nucleophilic. Such negative trend between acidity of the nucleophilic reagents and their effective nucleophilicity was previously demonstrated for a related base-assisted reaction of cyclopropenes with phenols.^{35,36} Evidently, the same tendency exists

for the reaction of sulfonamides. Indeed, a notable reduction of the yield of bicyclic product **9f** was observed in cyclization of *N*-brosylate **8f**, whereas nosylate **8g** reacted very sluggishly, and the corresponding product **9g** was formed only in marginal yield (Scheme 4).

Also, the possibility to carry out diastereoselective cyclization employing the 10-(4*S*,1*R*)-camphorsulfonyl group as a chiral auxiliary was evaluated. To this end, camphorsulfonamide **8h** was cyclized under the standard reaction conditions. The reaction proceeded smoothly, affording a 1 : 1 mixture of diastereomeric products **9h**. Evidently, asymmetric induction in this case was highly inefficient.

Conclusion

The utilization of various sulfonyls as activating groups in the cation-templated *8-exo-trig* nucleophilic additions of amines across the C=C bond of cyclopropenes was assessed. We demonstrated that most of the sulfonyls provide excellent yields of the corresponding eight-membered cyclic products. Electron-deficient sulfonamides, such as nosylate, afforded reduced

yields, showing a consistent limitation of the featured methodology. The possibility to carry out diastereoselective cyclization employing 10-(4*S*,1*R*)-camphorsulfonyl as a chiral auxiliary was evaluated. This reaction, however, afforded a 1 : 1 mixture of diastereomeric cyclic product, demonstrating the total inefficiency of such an approach.

General information

NMR spectra were recorded on a Bruker Avance DRX-500 (500 MHz) with a dual carbon/proton cryoprobe (CPDUL). ¹³C NMR spectra were registered with broadband decoupling. The (+) and (−) designations represent positive and negative intensities of signals in ¹³C DEPT-135 experiments. IR spectra were measured on a ThermoFisher Nicolet™ iS™ 5 FT-IR Spectrometer. HRMS was carried out on an LCT Premier (Micromass Technologies) instrument employing ESI TOF detection techniques. Glassware used in moisture-free syntheses was flame-dried under vacuum prior to use. Column chromatography was carried out on silica gel (Sorbent Technologies, 40–63 μm). Pre-coated silica gel plates (Sorbent Technologies Silica XG 200 μm) were used for TLC analysis. Anhydrous CH₂Cl₂, THF, and triethylamine were each prepared by refluxing commercially available solvent over CaH₂ followed by distillation under a stream of dry nitrogen at ambient pressure and stored over 3 Å molecular sieves under dry nitrogen. Anhydrous DMSO and DMF were prepared by stirring commercial solvents over CaH₂ at 100 °C and 80 °C, respectively, followed by distillation under reduced pressure. Thus, obtained dry solvents were stored over 3 Å molecular sieves under dry nitrogen. All other reagents, unless otherwise specified, were used in their commercially-available forms and purities. All manipulations of powdered KOH were conducted under inert atmosphere (<8 ppm residual oxygen and moisture) using a combination of glovebox and standard Schlenk techniques.

tert-Butyl (3-(*N*-benzyl-1-phenylcycloprop-2-ene-1-carboxamido)propyl)carbamate (**14**)

A flame-dried round bottom flask was charged with 1-phenylcycloprop-2-ene-1-carboxylic acid (**12**) (760 mg, 4.74 mmol, 1.00 equiv.), anhydrous dichloromethane (21 mL), and DMF (3 drops) under nitrogen atmosphere. Oxalyl chloride (623 μL, 903 mg, 7.12 mmol, 1.50 equiv.) was then added dropwise and the mixture was stirred at room temperature for 2 h. Volatiles were removed under reduced pressure to provide the crude acyl chloride. To a flame-dried flask containing *tert*-butyl (3-(benzylamino)propyl)carbamate hydrochloride (**13**) (1.65 g, 5.48 mmol, 1.16 equiv.), triethylamine (2.00 mL, 1.44 g, 14.2 mmol, 3.00 equiv.), and anhydrous dichloromethane (9.2 mL) was added dropwise a solution of the crude acyl chloride in anhydrous dichloromethane (6.1 mL). The reaction mixture was stirred for 16 hours at RT. The mixture was diluted with dichloromethane (40 mL) and washed with 1 N HCl (3 × 30 mL). The combined aqueous layers were back-extracted with dichloromethane (1 × 30 mL). The combined organic layers

were then washed with brine (1 × 20 mL), dried with MgSO₄, filtered, and concentrated under reduced pressure. The product was purified by column chromatography on silica gel eluting with CH₂Cl₂/EtOAc (7 : 1) to afford the title compound as a pale yellow oil (1.83 g, 4.50 mmol, 95%); *R*_f 0.36 (CH₂Cl₂/EtOAc, 7 : 1); NMR spectra indicate the presence of two rotamers (ratio of 2.6 : 1): ¹H NMR (500 MHz, CDCl₃) δ ppm [7.35 (s) & 7.33–7.12 (m) & 7.13 (d, *J* = 7.1 Hz) & 7.09 (s) & 6.94 (d, *J* = 6.9 Hz), Σ12H], [5.45 (t, *J* = 6.3 Hz) & 4.61 (s) & 4.49 (s) & 4.27 (m), Σ3H], [3.37 (t, *J* = 6.7 Hz) & 3.23 (m), Σ2H], [3.13 (q, *J* = 6.3 Hz) & 2.79 (q, *J* = 6.5 Hz), Σ2H], [1.66 (p, *J* = 6.5 Hz) & 1.41 (m), Σ11H]; ¹³C NMR (126 MHz CDCl₃) δ ppm 175.1, 174.4, 156.2, 155.9, 143.3, 143.0, 137.6, 137.0, 128.9 (+), 128.8 (+), 128.7 (+), 128.6 (+), 128.3 (+), 127.7 (+), 127.5 (+), 126.9 (+), 126.8 (+), 126.7 (+), 126.4 (+), 126.0 (+), 110.4 (+), 109.9 (+), 79.4, 79.1, 51.3 (–), 47.6 (–), 44.6 (–), 42.1 (–), 38.0 (–), 37.7 (–), 32.3, 32.1, 28.6 (+), 28.5 (+), 28.5 (–), 27.6 (–); FT-IR (NaCl, cm^{–1}): 3334, 3085, 3061, 3028, 2976, 2931, 1708, 1623, 1514, 1495, 1452, 1425, 1365, 1273, 1250, 1171, 997, 737, 700, 654, 605; HRMS (TOF ES): found 429.2149, calculated for C₂₅H₃₀N₂O₃Na [M + Na]⁺ 429.2154 (1.2 ppm).
