Formation of a mixed-valence Cu(I)/Cu(II) metal–organic framework with the full light spectrum and high selectivity of CO₂ photoreduction into CH₄†

Yajun Gao,^{†a} Lei Zhang,^{†d} Yuming Gu,^{†c} Wenwei Zhang,^{†e} Yi Pan,^a Weihai Fang,^c Jing Ma,^{*c} Ya-Qian Lan^{*d} and Junfeng Bai^{*ab}

Based upon the hetero-N,O ligand of pyrimidine-5-carboxylic acid (Hpmc), a new semiconductive Cu(I)/Cu(II) mixed-valence MOF with the full light spectrum and a novel topology of $\{4^3 \cdot 6^{12} \cdot 8^6\}_2\{4^3 \cdot 6^3\}_2\{6^3\}_6\{6^4 \cdot 8^2\}_3$, $\{(Cu_4I_4)_{2.5}[Cu_3(\mu_4-O)(\mu_3-I)(pmc)_3(Dabco)_3] \cdot 2.5DMF \cdot 2MeCN\}_\infty$ (NJU-Bai61, NJU-Bai for Nanjing University Bai group; Dabco = 1,4-diazabicyclo [2.2.2] octane), was synthesized stepwise. NJU-Bai61 exhibits good water/pH stabilities and a relatively large CO₂ adsorption capacity (29.82 cm³ g⁻¹ at 1 atm, 273 K) and could photocatalyze the reduction of CO₂ into CH₄ without additional photosensitizers and cocatalysts and with a high CH₄ production rate (15.75 μmol g⁻¹ h⁻¹) and a CH₄ selectivity of 72.8%. The CH₄ selectivity is the highest among the reported MOFs in aqueous solution. Experimental data and theoretical calculations further revealed that the Cu₄I₄ cluster may adsorb light to generate photoelectrons and transfer them to its Cu₃OI(CO₂)₃ cluster, and the Cu₃OI(CO₂)₃ cluster could provide active sites to adsorb and reduce CO₂ and deliver sufficient electrons for CO₂ to produce CH₄. This is the first time that the old Cu(I)_xY_yL_z coordination polymers' application has been extended for the photoreduction of CO₂ to CH₄ and this opens up a new platform for the effective photoreduction of CO₂ to CH₄.

Introduction

Due to climate change, CO₂ capture and conversion has recently become one of the greatest concerns.¹ In particular, the photoreduction of CO₂ into value-added chemicals (such as CO, HCOOH, CH₄, and so on) has attracted great attention, because it can be considered as a promising approach for solar-to-chemical energy conversion by mimicking the natural photosynthetic process to achieve a carbon neutral economy.² In the past few decades, diverse photocatalysts have been extensively employed for the photocatalytic CO₂ reduction reaction (CO₂RR).³ Homogeneous/molecular catalysts exhibit high selectivity and

efficiency, but low activity due to catalyst deactivation,⁴ whereas heterogeneous/inorganic catalysts show high activity and efficiency, but low selectivity.⁵ Very recently, due to their high surface area, inorganic–organic hybrid nature, structural and functional diversity and tunability, metal–organic frameworks (MOFs) may combine the advantages of the traditional homogeneous/heterogeneous catalysts and are emerging as promising platforms for the photocatalytic CO₂RR.⁶

Since 2011,⁷ many MOFs have been designed for the photocatalytic CO₂RR targeting to improve their efficiency, activity and selectivity by functionalizing organic ligands, optimizing metal ions/clusters, and making MOF-based composites.⁸ Although, some achievements have been made, research on MOF-based photocatalysts to date is still in its early stages. In terms of the reductive products, most reported MOFs predominantly produce the 2e⁻/2H⁺ products of CO/HCOOH.^{8a,9} Due to the fact that the photocatalytic reduction of CO₂ into CH₄ is more difficult than with other C1 fuels, because it involves a complex 8e⁻/8H⁺ reduction process, *i.e.*, multiple steps of hydrogenation and deoxygenation reactions, and requiring the highest kinetic barrier of up to 818.3 kJ mol⁻¹,¹⁰ the reported MOF catalysts capable of producing even low or moderate yields of CH₄ are still rare. Thus, design of MOFs with high selectivity for the reduction of CO₂ into CH₄ is a great challenge.¹¹

The Cu(I)_xY_yL_z (where X = Cl, Br or I; L = N, P or S containing organic ligands) are almost the oldest coordination polymers

‡ These authors contributed equally to this work.

with diversified structures and interesting properties, such as luminescence and semiconductivity, and so on.¹² Very recently, their use has been demonstrated for photocatalytic H₂ evolution.¹³ Herein the exploration of these polymers as promising platforms for CO₂ capture and conversion is reported. From a simple hetero-N,O ligand pyrimidine-5-carboxylic acid, a Cu₄I₄ and Cu₃OI(CO₂)₃ cluster based and semiconductive Cu(I)/Cu(II) mixed-valence MOF (**NJU-Bai61**) with a full light spectrum, which exhibits good water and pH stabilities and the relatively large CO₂ adsorption capacity (29.82 cm³ g⁻¹ at 1 atm, 273 K) was successfully constructed. In addition, **NJU-Bai61** could photocatalyze the reduction of CO₂ into CH₄ without additional photosensitizers and cocatalysts and with a high CH₄ production (15.75 μmol g⁻¹ h⁻¹) and CH₄ selectivity of 72.8%. As far as is known, the CH₄ selectivity is the highest among the reported MOFs in the aqueous solution. Upon light irradiation, its Cu₄I₄ clusters as photoelectron generators could transfer photoelectrons to the Cu₃OI(CO₂)₃ clusters, whereas the Cu₃OI(CO₂)₃ clusters could provide active sites for adsorbing and reducing CO₂ and act as photoelectron collectors for delivering enough electrons to CO₂ for CH₄ evolution.

Results and discussion

From CuI and the Hp_{mc} ligand and using Dabco as the structural directing agent, like many Cu(I)_xX_yL_z, a Cu₄I₄ cluster-based

Scheme 1 A schematic view of the preparation of **NJU-Bai61**.

copper(I) coordination polymer, $\{(\text{Cu}_4\text{I}_4)(\text{Hp}_{\text{mc}})_2\}_\infty$ (**NJU-Bai61p**) was initially obtained. **NJU-Bai61p** is a 2D layered and 4-connected network with sql topology (Fig. S3, ESI[†]), in which each Hp_{mc} ligand uses its N-donor center to link to a 4-coordinated Cu(I) in a tetrahedral coordination geometry resulting in a [Cu₄I₄N₄] moiety, leaving its COOH functional group uncoordinated (Fig. S4, ESI[†]).

Later on, by changing the acid and extending the time, **NJU-Bai61p** was further transformed into **NJU-Bai61** (Scheme 1). Compared with **NJU-Bai61p**, the Hp_{mc} ligands in **NJU-Bai61** were deprotonated, coordinated with Cu(II) ions in a bridging bidentate mode, facilitating the formation of the Cu₃OI(CO₂)₃ cluster. The Cu₃OI(CO₂)₃ cluster is 7-connected and surrounded by one Cu₄I₄ cluster, three pmc and three Dabco auxiliary ligands. All the Cu(II) ions in this new cluster adopt 5-coordinated geometry with two O atoms from two independent pmc linkers, one N atom from the Dabco linker, one μ₃-I⁻ ion shared by three Cu(II) ions, and one μ₄-O²⁻ ion shared by three Cu(II) ions and one Cu(I) ion from the Cu₄I₄ cluster (Fig. S6, ESI[†]). Remarkably, the Cu₄I₄ clusters in **NJU-Bai61** exist in two different coordination environments. One is the same as that of **NJU-Bai61p** and can form a 4-connected [Cu₄I₄N₄] moiety, whereas the other is the Cu₄I₄ cluster which is linked by three N atoms from three Dabco ligands and one μ₄-O²⁻ ion to form a 4-connected [Cu₄I₄N₃O] moiety (Fig. S5, ESI[†]).

Furthermore, these Cu₄I₄ and Cu₃OI(CO₂)₃ clusters are bridged by pmc and Dabco ligands to form two types of cubic cages. The larger one (cage A) is composed of four Cu₄I₄ clusters and four Cu₃OI(CO₂)₃ clusters arranged alternately as vertices and 12 linear Dabco ligands as edges with a diameter of about 8.0 Å (Fig. 1c). The smaller one (cage B) is composed of eight pairs of [Cu₄I₄-Cu₃OI(CO₂)₃] linkage clusters as vertices and 12 Dabco ligands as edges, in which there exists a square with a diameter of about 6.4 Å based on four pmc linkers and Cu₄I₄ clusters located at the center of the four facets of this cage

Fig. 1 (a) and (b) Cu₄I₄ and Cu₃OI(CO₂)₃ clusters are illustrated by two types of tetrahedrons; (c) and (d) two types of cubic cages in **NJU-Bai61**: cage A, lavender; cage B, lime; (e) the 1D channel consists of the cages A and B; (f) the 1D cage-stacked chain consists of cages B; (g) the 3D framework of **NJU-Bai61** with the 1D channels and chains.

(Fig. 1d and S7, ESI†). The cages A and B connect alternately with each other to form a 1D channel by sharing quadrilateral windows, whereas the B cages connect with each other to form a 1D cage-stacked chain by sharing the facets including a quadrilateral window and a Cu_4I_4 cluster (Fig. 1e, f, and S8, ESI†). Therefore, these 1D channels and chains are arranged in an alternating fashion to form a 3D porous framework based on the cages A and B ratio of 1 : 3, in which each cage A shares facets with six cage Bs and each cage B shares facets with two cage As and four cage Bs (Fig. 1g and S9, ESI†). From the viewpoint of structural topology, pmc ligands, Cu_4I_4 and $\text{Cu}_3\text{-OI}(\text{CO}_2)_3$ clusters could be regarded as 3-connected triangular nodes, 4-connected tetrahedral nodes, and 7-connected single cap octahedron nodes, respectively. Consequently, **NJU-Bai61** is a new (3,4,4,7)-connected network with the point symbol $\{4^3 \cdot 6^{12} \cdot 8^6\}_2\{4^3 \cdot 6^3\}_2\{6^3\}_6\{6^4 \cdot 8^2\}_3$ (Fig. S10, ESI†).

The phase purities and thermal stabilities of **NJU-Bai61p** and **NJU-Bai61** were confirmed using PXRD and TG analyses (Fig. S13 and S14, ESI†). As shown in Fig. S15–S17 (ESI†), they are quite stable under water and other organic solvents. Furthermore, they are also stable under the broad variation of the pH values.

NJU-Bai61p exhibits a visible light adsorption up to 550 nm due to the Cu_4I_4 cluster to linker charge transfer (CLCT) transition (Fig. 2a and Table S2, ESI†). Very interestingly, **NJU-Bai61** shows the widest absorption band among the reported MOFs with the edge up to 1400 nm, which are mainly dominated by intra metal cluster transfer (ICT), CLCT, and metal cluster-to-metal cluster charge transfer (CCCT) transitions (Fig. 2a and Table S3, ESI†). The bandgaps of semiconductive **NJU-Bai61p** and **NJU-Bai61** were estimated to be 2.33 eV and 0.92 eV, respectively, (Fig. S18, ESI†), which could be correlated with the calculated HOMO–LUMO gaps of 2.16 eV and 1.25 eV for the corresponding cluster models, respectively, (Tables S4 and S5, ESI†). The solid state of **NJU-Bai61** with a periodic boundary condition (PBC) model for the band gap was further calculated, showing a narrow band gap of 0.65 eV (Fig. S19, ESI†). The Mott–Schottky measurements further revealed that they were

typical n-type semiconductors and their conduction bands (CB) were -0.55 V and -0.58 V, which were more negative than the reduction potentials for the conversion of CO_2 to CO and CH_4 (Fig. 2b and S20, ESI†).^{8a} Thus, they are very promising for the CO_2 photoreduction applications.

The photocatalytic reduction of CO_2 over the activated **NJU-Bai61** was further investigated. The amount of CH_4 was 1.26 μmol (*i.e.*, $15.75 \mu\text{mol g}^{-1} \text{h}^{-1}$) after 4 h. Except for the small amounts of CO ($0.32 \mu\text{mol}$, *i.e.*, $4 \mu\text{mol g}^{-1} \text{h}^{-1}$) and H_2 ($0.15 \mu\text{mol}$, *i.e.*, $1.87 \mu\text{mol g}^{-1} \text{h}^{-1}$), no other products, such as HCOOH , CH_3OH and HCHO , were detected (Fig. 2c, S22 and S23, ESI†). The **NJU-Bai61** exhibited a CH_4 selectivity of 72.8% in aqueous solution, which was the highest among the reported MOFs (Table S8, ESI†). No obvious change of the CH_4 activity occurred during the four continuous runs (Fig. S24, ESI†). The XRD patterns obtained before and after its photocatalytic experiments revealed the structural robustness of the catalyst (Fig. S27, ESI†). The isotopic $^{13}\text{CO}_2$ tracing experiment was also performed to confirm that the carbon source of CH_4 did indeed come from the used CO_2 rather than the degradation of organics in the reaction (Fig. 2d).^{11b} For comparison, the use of **NJU-Bai61p** as the photocatalyst was also investigated under the same conditions and only CO ($1.37 \mu\text{mol}$, *i.e.*, $17.13 \mu\text{mol g}^{-1} \text{h}^{-1}$) and H_2 ($1.34 \mu\text{mol}$, *i.e.*, $16.75 \mu\text{mol g}^{-1} \text{h}^{-1}$) were detected after 4 h (Fig. S25, ESI†). This result may reveal that $\text{Cu}_3\text{OI}(\text{CO}_2)_3$ clusters in **NJU-Bai61** could provide active sites for CH_4 evolution.

Then in-depth research was carried out to discover the reason underlying the high efficiency of CH_4 evolution. As for **NJU-Bai61**, the BET surface area was $248.1 \text{ m}^2 \text{ g}^{-1}$ and the CO_2 uptakes at 273 K and 298 K were 29.82 and $19.69 \text{ cm}^3 \text{ g}^{-1}$, respectively, which was helpful for the subsequent CO_2 conversion (Fig. S28–S30, ESI†). The electrostatic potential analysis may further reveal that the $\text{Cu}(\text{II})$ centers in $\text{Cu}_3\text{-OI}(\text{CO}_2)_3$ clusters are the most favorable sites for the nucleophilic attack of CO_2 (Fig. S31, ESI†). The local interactions between $\text{Cu}(\text{II})$ sites and CO_2 molecules were investigated using the *in situ* FTIR technology. The adsorption of CO_2 onto the $\text{Cu}(\text{II})$ sites in **NJU-Bai61** was a 16 cm^{-1} red shift of the asymmetric stretching mode of CO_2 ($\nu = 2359 \text{ cm}^{-1}$), indicating the stronger binding between the CO_2 and $\text{Cu}(\text{II})$ sites (Fig. S33, ESI†).^{11b} However, for **NJU-Bai61p**, no shift existed after CO_2 adsorption (Fig. S32, ESI†). Moreover, this experimental phenomenon was explained by the DFT calculations in which the peaks were also red-shifted and the adsorbed CO_2 molecule takes a slightly bent geometry to facilitate the CO_2 activation (Fig. S34 and Table S9, ESI†).¹⁴ Furthermore, its fluorescence was quenched in comparison to **NJU-Bai61p**, indicating that the photo-excited electrons of the Cu_4I_4 clusters were transferred to the $\text{Cu}_3\text{OI}(\text{CO}_2)_3$ clusters, making it act as a photoelectron collector to provide electrons for the adsorbed CO_2 (Fig. S35, ESI†).

An energetically feasible reaction pathway was calculated using DFT with the relative free energy, ΔG , for each step shown in Fig. 3 and S38 (ESI).[†] Upon light irradiation, the Cu_4I_4 clusters in **NJU-Bai61** may adsorb light to generate the photoelectrons and transfer them to the $\text{Cu}_3\text{OI}(\text{CO}_2)_3$ clusters, whereas

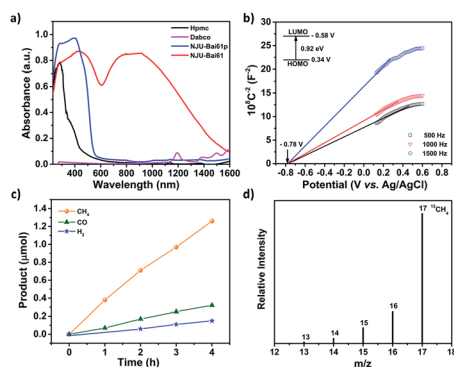

Fig. 2 (a) The UV-Vis-NIR absorption spectra of **NJU-Bai61p** and **NJU-Bai61**; (b) Mott–Schottky plots for **NJU-Bai61**; (c) the amounts of CH_4 , CO and H_2 produced as a function of the irradiation time over **NJU-Bai61**; (d) the mass spectral analysis of $^{13}\text{CH}_4$ recorded under a $^{13}\text{CO}_2$ atmosphere using **NJU-Bai61** as the catalyst.

Fig. 3 A proposed reaction pathway together with free energy difference (ΔG) for the photocatalytic CO_2 -to- CH_4 conversion over NJU-Bai61.

the $\text{Cu}_3\text{OI}(\text{CO}_2)_3$ clusters could supply electrons to the adsorbed CO_2 for CH_4 evolution. In the first step, the adsorbed CO_2 molecule accepted an electron and a proton to generate the COOH^* . Then the COOH^* combines with the second electron-proton pair to generate CO^* . The CO^* was reduced to the CHO^* by accepting two electrons and a proton, and further combined with a total of four electrons and five protons to generate CH_4 . In the photocatalytic process, the Cu_4I_4 cluster could serve as a photosensitizer and donated the energy of 2.16 eV to the conversion process of CO^* to CHO^* at the $\text{Cu}_3\text{OI}(\text{CO}_2)_3$ cluster which was an endothermic process with the ΔG of 1.2 eV. Moreover, the stronger CO binding affinity on NJU-Bai61 ($E_b = -20.13$ eV) in comparison with that on only Cu(I)-containing NJU-Bai61p ($E_b = -8.05$ eV) may further stabilize the $\text{CO}@\text{Cu}_3\text{OI}(\text{CO}_2)_3$ complex to complete the CO_2 -to- CH_4 conversion (Fig. S39, ESI †).

Conclusions

In summary, a novel Cu_4I_4 and $\text{Cu}_3\text{OI}(\text{CO}_2)_3$ cluster based and semiconductive Cu(I)/Cu(II) mixed-valence MOF with the full light spectrum, NJU-Bai61, was successfully produced, which exhibits good water stability, pH stability and a relatively large CO_2 adsorption capacity. NJU-Bai61 could photocatalyze the reduction of CO_2 into CH_4 , without additional photosensitizers and cocatalysts, but with a high CH_4 production and significantly high CH_4 selectivity of 72.8% (the highest among the reported MOFs in aqueous solution). It was revealed that the Cu_4I_4 and $\text{Cu}_3\text{OI}(\text{CO}_2)_3$ clusters may play the role of photo-electron generators and collectors, respectively. This work firstly expands the old $\text{Cu}(\text{I})_x\text{X}_y\text{L}_z$ coordination polymers' application into the reduction of CO_2 to CH_4 and may open up a new system of MOFs for the reduction of CO_2 to CH_4 with high selectivity.

Experimental section

Synthesis of NJU-Bai61p

A mixture of Hpme (11 mg, 0.09 mmol), CuI (30 mg, 0.16 mmol), Dabco (6 mg, 0.05 mmol), H_2SO_4 (10 μL), DMF (1.0 mL), and MeCN (3.0 mL) was sealed in a 20 mL Pyrex tube and kept in an oven at 85 $^\circ\text{C}$ for 1 day. After washing with DMF, yellow block

crystals were obtained. Yield: 2.5 mg (6%). Selected IR (cm^{-1}): 3036, 2666, 2554, 1713, 1586, 1441, 1398, 1330, 1297, 1202, 1170, 1119, 1090, 1054, 996, 908, 837, 749, 695, 667, 568. Elemental analysis (%) calcd. for $\text{Cu}_2\text{L}_2\text{C}_5\text{H}_4\text{N}_2\text{O}_2$: C 11.89, H 0.80, N 5.54; found: C 11.96, H 1.00, N 5.52.

Synthesis of NJU-Bai61

A single crystal of NJU-Bai61p (10 mg), Dabco (4 mg, 0.036 mmol) and CuI (20 mg, 0.11 mmol) were added to 1.0 mL of DMF and 3.0 mL of MeCN. To this was added 60 μL of HCOOH with stirring. The mixture was sealed in a Pyrex tube and heated to 85 $^\circ\text{C}$ for 2 d. Dark-red octahedral crystals were obtained and further characterized by PXRD and the results are shown in Fig. S1 (ESI †). Yield: 8.8 mg (25%). Selected IR (cm^{-1}): 3392, 3108, 2952, 2883, 2840, 1681, 1652, 1587, 1435, 1377, 1319, 1218, 1170, 1087, 1050, 1000, 924, 840, 805, 764, 700, 612, 583, 468, 420. Elemental analysis (%) calcd. for $\text{Cu}_{13}\text{I}_{11}\text{C}_{44.5}\text{H}_{68.5}\text{N}_{16.5}\text{O}_{9.5}$: C 16.66, H 2.15, N 7.20; found: C 16.87, H 2.30, N 6.98.

Sample activation

The as-synthesized sample of NJU-Bai61 was soaked in MeOH for 5 d with refreshing of the MeOH every 8 h. Then, the solvent-exchanged sample was activated at 70 $^\circ\text{C}$ and under vacuum for 10 h to obtain the activated NJU-Bai61.

Photocatalytic reaction

The photocatalytic CO_2 reduction experiments were carried out on an evaluation system (CEL-SPH2N, CEAULIGHT, China), in a 100 mL quartz container. A 300 W xenon arc lamp ($300 < \lambda < 2500$ nm) was utilized as the irradiation source. The 20 mg MOFs (NJU-Bai61p or the activated NJU-Bai61) were dispersed in 50 mL of a solution of triethylamine and water ($\text{TEA}/\text{H}_2\text{O} = 5 : 45$ v/v). The suspension was pre-degassed with CO_2 (99.999%) for 30 min to remove the air before irradiation. The reaction was stirred constantly with a magnetic bar to ensure the photocatalyst particles remained in suspension. The temperature of the reaction was maintained at 25 $^\circ\text{C}$ by a circulating cooling water system. The gaseous product was measured by gas chromatography (GC-7900, CEAULIGHT, China) with a flame ionization detector (FID) and a thermal

conductivity detector (TCD). An ion chromatography (LC-2010 Plus, Shimadzu, Japan) was used for the detection of HCOO^- . The concentration of Cu in the solution before and after catalysis was determined using an ICP-OES system (Optima 5300 DV, PerkinElmer). Before the photocatalytic reaction, the suspension of the activated **NJU-Bai61** (220 mg), TEA (5 mL) and H_2O (45 mL) was pre-degassed with CO_2 (99.999%) for 30 min to remove the air, then 2 mL of the filtrate was removed and a Cu concentration of 0.6 mg L^{-1} was detected. Thus, the concentration of dissolved Cu ions of the activated **NJU-Bai61** was 0.05% before catalysis. After the photocatalytic reaction, 2 mL of filtrate was also removed and the concentration of Cu in the filtrate was determined to be 13.8 mg L^{-1} . Thus, the concentration of dissolved Cu ions of the activated **NJU-Bai61** was 1.1%. The cycling experiment was carried out as follows: at the end of each run, the suspension was centrifuged and the supernatant was removed. Then the recovered catalyst was washed with distilled water and dried in air at 60°C before the next cycle.
