A titanium dioxide–carbon nanotube hybrid to simultaneously achieve the mechanical enhancement of natural rubber and its stability under extreme frictional conditions†

Le Wan, Cong Deng, * Ze-Yong Zhao, Hai-Bo Zhao  and Yu-Zhong Wang

Currently, carbon black as an efficient reinforcing agent dominates the reinforcement field of natural rubber (NR). However, its general loading amount is quite high for achieving the reinforcement of NR. In this work, titanium oxide–carbon nanotubes (TiO₂–CNTs) were prepared by using the hydrothermal method. When a small amount of TiO₂–CNTs additive was used to reinforce NR, significant mechanical enhancement was achieved. Experimental results confirmed that the tensile strength and elongation at the break of NR containing 3.0 wt% TiO₂–CNTs (NR/3TiO₂–CNTs) were 32.0 MPa and 1604%, corresponding to an increase by about 79.5% and 14.5%, respectively, in comparison with that of pristine NR. Moreover, thermal analysis confirmed that the initial decomposing temperature of NR was promoted to 313.5 °C from 287.9 °C after the incorporation of only 3 wt% TiO₂–CNTs, which was raised by 25.6 °C. An intensive friction test confirmed that the maximum temperatures at the surfaces of NR/3TiO₂–CNTs and NR/5TiO₂–CNTs were 217 and 210 °C, respectively, which decreased by 29 and 36 °C in comparison with that of NR. The study of the mechanical enhancement confirmed that the uniform dispersion of TiO₂–CNTs and superior interfacial interactions between NR and TiO₂–CNTs played a dominant role in the mechanical enhancement of NR/TiO₂–CNTs composites. For the improved stability of NR/TiO₂–CNTs composites, the physical barrier action of TiO₂–CNTs to heat and oxygen, excellent heat dispersion of CNTs, and the increased graphitization degree at the surface played a vital role. The TiO₂–CNTs show specific advantages in simultaneously reinforcing the mechanical properties of NR and promoting its stability under extreme friction condition.

1. Introduction

The working environment of aircraft tires is very harsh during landing, including high speed, high load, high temperature, and intensive friction. In this case, the temperature at the tread of the aircraft tires rises sharply and the instantaneous temperature can reach 300–400 °C, which causes the tread of the aircraft tires to be damaged easily; this kind of damage is a great threat to the safety of human beings and aircrafts. In the current work, carbon black was applied to reinforce NR. As an efficient reinforcing agent, carbon black dominates the reinforcing field of NR. Moreover, it has also been confirmed that carbon black-reinforced NR possesses high thermal stability. Matheson *et al.*¹

studied the effect of carbon black on the thermal decomposition behavior of NR and results showed that the presence of carbon black did not apparently have any negative affect on the thermal stability of NR. Although carbon black has its own advantages in reinforcing NR, the high loading amount of carbon black is a shortcoming in the case of fulfilling the requirements of mechanical, high-temperature stability, and other properties in fabricating the tread material of aircraft tires.

In order to prepare NR composites with excellent mechanical properties and high-temperature stability, many researchers have done much work. In terms of the thermal stability of NR composites, some researchers have deeply investigated the thermal decomposition behavior of NR and further explored some novel NR-based composites. Straus *et al.*² studied the thermal decomposition behavior of vulcanized rubber under vacuum condition and found that the crosslinking bond was easy to break at the pyrolysis temperature; also, the effect of crosslinking became invalid at a higher temperature. Ginger *et al.*³ studied the thermal decomposition behavior of crosslinked polyisoprene and found that the molecular chain rearranged and resulted in the formation

of terminal double bond during heating. In addition, due to the crosslinking, both the thermal stability and thermal-oxidation stability were enhanced. For NR, both vulcanization and crosslinking may affect the type and yield of the thermal decomposition products. Generally, the yield of the produced monomers and dimers will decrease with increasing crosslinking density, but the yield of 3-methyl-1,3-pentylene will not remarkably fluctuate with the change in the crosslinking density.^{4–6} Chen *et al.*⁷ pyrolyzed *cis*-1,4-polyisoprene at different temperature ranges; the results showed that the concentrations of isoprene and dipentene formed at relatively low temperature were higher. At relatively high temperature, a high yield of hydrocarbon was obtained due to the intensive decomposition of the polymer.^{8–10}

On the basis of the above fundamental research, some novel NR-based composites with improved thermal stability and mechanical properties were developed, in which nanoparticles have been proved to be very efficient to achieve the improved thermal properties. Here, nanoparticles mainly contain carbon nanotubes, modified montmorillonite (MMT), silica, calcium carbonate, carbon black, and starch. Khanlari *et al.*¹¹ used modified MMT to promote the thermal stability of NR. The results confirmed that the thermal decomposition of the MMT-filled nanocomposites shifted towards the higher temperature range, and the temperatures at 20 and 50 wt% mass loss were increased by 20 and 15 °C, respectively. Among different types of nanofillers, CNTs have also been demonstrated to be very efficient in improving the thermal stability and mechanical properties of NR. Fakhru' I-Razi *et al.* found that a high strain value was obtained for the nanocomposite with 1.0 wt% CNTs. Moreover, better heat dispersion and higher thermal stability were simultaneously achieved for the NR/CNTs nanocomposites. However, due to the fact that CNTs are easy to agglomerate and entangle, they are difficult to uniformly disperse in the matrix.^{12,13} In addition, it has been confirmed that TiO₂ nanoparticles can improve the thermal stability and high temperature resistance of polymers. Hayeemasae *et al.*¹⁴ found that TiO₂ nanoparticles had an apparent influence on the thermal stability of NR. The results showed that the decomposition temperatures at 10 and 50% weight loss for NR composite were remarkably raised when a small amount of TiO₂ was added in the NR composite.

According to a previous report,¹⁵ compared with the mono-component filler, the synergy of two or more kinds of reinforcing materials can improve the dispersion of fillers and meanwhile endow rubber with better specific properties or better comprehensive properties. Therefore, the joint action of CNTs and TiO₂ might have a positive influence on the mechanical enhancement and thermal stability of NR. In this work, the TiO₂-CNTs were prepared by the sol-gel method and used to fabricate the NR/TiO₂-CNT composite *via* the latex composite method in order to fabricate the NR composites with excellent comprehensive properties.¹⁶ The mechanical properties and stability of the NR composites were investigated with the aid of different measurements. Moreover, the corresponding mechanisms for the improved mechanical properties and stability were discussed in detail.

2. Experimental section

2.1. Materials

NR was purchased from Tianjin Changli Rubber Co., Ltd (China), whose dry rubber content (DRC) was about 60%. Carbon black (CB, N330) was supplied by Cabot Corporation (USA). Carbon nanotubes (TNSMC3, hydroxylation, industrial grade) were provided by Institute of Organic Chemistry (Chinese Academy of Sciences), and their outer diameter and length are about 10–20 nm and 0.5–2.0 μm, respectively. Anhydrous ethanol (analytical reagent), titanium isopropanol (analytical reagent), isopropanol (analytical reagent), and formic acid (analytical reagent) were purchased from Chengdu Kelong Chemical Reagent Factory (China). Deionized water was self-made. Sulfur (industrial grade) was obtained from Yisheng New Material Co., Ltd (China). Zinc oxide (industrial grade) was produced by Dalian Zinc Oxide Co., Ltd (China). Stearic acid (SA) was purchased from Taike Browning Co., Ltd (China). The antioxidant *N*-isopropyl-*N'*-phenyl-4-phenylenediamin (4010NA) was purchased from Sinopec Group Nanjing Chemical Industry Co., Ltd (China). Vulcanization accelerator (CZ) was supplied by Kemai Chemical Co., Ltd (China).

2.2. Preparation of TiO₂-CNTs nanoparticles

First, 109.2 mL deionized water and 10.8 mL isopropanol were mixed in a 250 mL flask. Then, CNTs were added into the mixed solution containing isopropanol. After being stirred for 2 h, the CNT solution was obtained. Next, 13.6 mL titanium isopropanol was slowly added to the CNT solution through the separating funnel and the dripping time was about 30 min. Then, the hydrolysis reaction was maintained for 2 h at room temperature, accompanied by stirring. Afterwards, the product was washed with absolute ethanol and deionized water, and then the washed products were put into a vacuum oven and dried at 80 °C for 5 h. Finally, the TiO₂-CNTs nanoparticles were obtained.

2.3. Preparation of the NR/TiO₂-CNTs nanocomposites

The NR/TiO₂-CNTs composites were prepared by adding different contents of TiO₂-CNTs into the NR latex, as shown in Table 1. Firstly, TiO₂-CNTs nanoparticles were added into a large beaker containing 200 mL deionized water. After stirring for 1 h, followed by ultrasonic treatment for 2 h, the latex was slowly added into the beaker and stirred for 3 h. Here, the sonication power was 300 W. Then, formic acid solution was slowly incorporated in the mixed solution until it was completely demulsified and settled. Then, the

Table 1 The formulation of the composites

Materials	Additive contents (phr ^a)				
NR	100	100	100	100	100

^a The number in the front of the materials represent its content and the unit is phr.

rubber composites were cut into small pieces and washed with deionized water and ethanol until the formic acid was completely removed. Finally, these small pieces were put into a vacuum oven and dried at 80 °C for 12 h, and then the NR/TiO₂-CNTs nanocomposites were obtained. Finally, different NR/TiO₂-CNTs nanocomposites were mechanically blended with the vulcanizing agent, curing agent, and other additives by an open mixer. During mixing, the speed of the mill was 60 rpm and the nip gap of the mill was 0.5 mm. After blending, these rubber composites were vulcanized by a flat curing machine (Qingdao Yadong Rubber Machinery Co. Ltd, China) at 150 °C and then pressing was continued for 5 min at room temperature to maintain their shape. Here, the curing time (10 min) was determined by t_{90} . In hydraulic heating press, the pressure was 15 MPa and the size of the mold was 100 mm × 100 mm × 2 mm. Finally, the vulcanized NR/TiO₂-CNTs plates was tailored by a specific cutter according to the test standards. In addition, 50 phr carbon black enhanced NR composites, which were used for the friction test, were also prepared according to the same procedure as that mentioned above.

2.4. Measurements

Thermogravimetric analysis (TGA) was carried out on a thermal analyzer (NETZSCH, TG209, Germany) under nitrogen/air atmosphere and the heating rate was 10 °C min⁻¹. The mechanical properties of NR and the NR/TiO₂-CNTs composites were measured by a mechanical test machine (Instron 3366, USA) according to the standard GB/T 528-2009. The friction test was performed on a friction test machine (UMT-TriboLab, Bruke USA), and the applied rotating speed and pressure were 1800 rpm and 500 N during the friction time of 30 s, respectively. Rebound resilience

property, hardness, and abrasion tests of the NR and NR/TiO₂-CNTs composites were measured according to the standard GB/T 1681, GB/T 9867, and GB/T 531, respectively. Compression recovery ratios of NR and NR/TiO₂-CNTs composites were obtained according to GB/T 7759, and the compression set, compression time, and temperature were 25%, 24 h, and 100 °C, respectively. An infrared thermal imager (FTLR T420) was used to track the temperature at the surface of the samples. The surface morphology was examined by a scanning electron microscopy (SEM) (JEOL JSM 5900LV, Japan) and a Karl Zeiss LSM 800 Confocal Microscope (LSM800 Carl Zeiss Germany). In the SEM test, the used accelerating voltage was 10 kV. An X-ray energy dispersion spectrum (EDX) analyzer (Inca Penta-Fetx3 Oxford, USA) was used to measure the element contents of different samples. Transmission electron microscopy (TEM, model H-800, Hitachi, Japan) of the nanoparticles was completed at an accelerating voltage of 200 kV. FTIR spectra in the range of 4000–400 cm⁻¹ were recorded using a Nicolet 6700 spectrometer (Thermo Fisher Scientific, USA). X-ray diffraction (XRD) patterns were recorded by a DX-1000 X-ray diffractometer (PANalytical B.V., Holland) in the 2θ range of 5–80° using Cu-K α radiation ($\lambda = 1.542 \text{ \AA}$). A SPEX Raman apparatus (1403, USA) was used to record the laser Raman spectroscopy (LRS) in the scanning range of 500–2200 cm⁻¹ using the excitation wavelength of 532 nm.

3. Results and discussion

3.1. Structural characterization of TiO₂-CNTs

The SEM micrographs of CNTs, TiO₂, and TiO₂-CNTs are shown in Fig. 1. The surface of the CNTs is quite smooth. From

Fig. 1 SEM micrographs of CNTs (a), TiO₂ (b), and TiO₂-CNTs (c); TEM micrographs of CNTs (d₁ and d₂) and TiO₂-CNTs (e₁ and e₂); EDX spectra of TiO₂-CNTs (f).

Fig. 2 XRD patterns of CNTs and TiO₂-CNTs.

Fig. 1b, it can be observed that there are many TiO₂ particles and these particles agglomerate together. After hybridizing with CNTs using TiO₂, many small TiO₂ particles adhere at the surface of the CNTs and some of them also aggregate at the outer wall. To clearly illustrate the microstructure, the TEM test

was used to further analyze the CNTs and TiO₂-CNTs. Fig. 1d shows that the surface of the CNTs is very smooth, which is consistent with that shown in Fig. 1a. For the TiO₂-CNTs, the tubular structure can be clearly seen, for which the inner tube is the CNTs and outer particles are TiO₂. From the SEM and TEM results, it was revealed that TiO₂ particles were formed at the surface of the CNTs *via* a dehydration condensation process. In addition, EDX was performed to determine the component of TiO₂-CNTs. According to Fig. 1f, the TiO₂-CNTs mainly consist of C, O, and Ti elements, which further illustrates that the hybrid TiO₂-CNTs was formed.

The prepared TiO₂-CNTs were further characterized by XRD. The result is shown in Fig. 2. For CNTs, the diffraction peak at $2\theta = 26^\circ$ is ascribed to their (002) reflection. When the CNTs are hybridized by TiO₂, several new peaks appear at $2\theta = 25.2^\circ$, 37.8° , 48.1° , 53.9° , 55.1° , and 62.7° besides those ascribed to CNTs, which correspond to (101), (004), (200), (105), (211), and (204) crystal planes of anatase TiO₂.¹⁷ The XRD result indicates that the crystalline structures of both TiO₂ and CNTs were not affected by the hybridization reaction between them. In order to further illustrate the structure of the TiO₂-CNTs, Raman spectroscopy was performed for the CNTs and TiO₂-CNTs. The results are shown in Fig. 3. In the Raman spectra, two absorption peaks located at about 1342 and 1576 cm⁻¹ correspond to the D and G

Fig. 3 Raman spectra of CNTs and TiO₂-CNTs.

Fig. 4 TG (a) and DTG (b) results of CNTs and TiO₂-CNTs.

Fig. 5 TG (a) and DTG (b) curves of the NR/TiO₂-CNTs composites in N₂ atmosphere.

bands of graphitized carbon, respectively.¹⁸ The intensity ratio of the D to G bands (I_D/I_G) can be used to characterize the change in the defect degree of the CNTs. The I_D/I_G for CNTs is 0.919, which is only slightly higher than 0.835 for TiO₂-CNTs, showing no significant change in the graphitization degree of the CNTs. Clearly, the graphitization of CNTs was not remarkably affected by the hybridization reaction with TiO₂.

3.2. Thermal properties of CNTs and TiO₂-CNTs

TGA was used to further characterize the thermal properties of TiO₂-CNTs. The result is shown in Fig. 4. As a comparison, CNTs were also analyzed by TGA. Both TiO₂-CNTs and CNTs show only one decomposition stage from 40 to 700 °C under air atmosphere and their initial decomposition temperatures have no apparent difference. For the CNTs, the residue at 700 °C is significantly lower than that of the TiO₂-CNTs, which should be due to the oxidation of CNTs. For the TiO₂-CNTs, the initial

decomposition temperature is close to that of the CNTs. However, the residual mass of the TiO₂-CNTs is significantly higher than that of the CNTs, which is mainly due to the high residual mass of TiO₂ at high temperature.¹⁶ Here, the mass percentage plot of CNT shows an upside trend after 650 °C, which should be due to the unstable gas flow after 650 °C. Obviously, the prepared TiO₂-CNTs possess high thermal stability.

3.3. Thermal properties of the NR/TiO₂-CNT composites

The TGA results of different NR/TiO₂-CNTs composites are shown in Fig. 5 and Table 2. The $T_{5\%}$ and T_{max} are the decomposition temperature at 5 wt% mass loss and the decomposition temperature at the maximum mass loss rate, respectively. MLR_{max} is the maximum mass loss rate. In nitrogen atmosphere, the initial decomposition temperature of NR/1TiO₂-CNTs is 332.1 °C, which increased by 24 °C compared with that of NR. Clearly, a small amount of TiO₂-CNTs significantly improved the thermal stability of NR. The initial decomposition temperature of the NR/TiO₂-CNTs gradually increases on raising the content of TiO₂-CNTs. However, the change in the temperature increase is quite low with increasing TiO₂-CNTs content from 1 to 5 phr. According to previous studies,^{19–21} it can be concluded that the increase in the initial decomposition temperature of NR after the incorporation of the TiO₂-CNTs should mainly be attributed to the thermal conductivity and physical isolation of

Table 2 Detailed TG data of the NR/TiO₂-CNTs composites in N₂ atmosphere

Samples	$T_{5\%}$ (°C)	T_{max} (°C)	MLR _{max} (%/°C)	Residue (%)
NR	308.8	381.4	14.3	3.2
NR/1TiO ₂ -CNTs	332.1	381.1	14.3	6.0
NR/2TiO ₂ -CNTs	334.4	381.6	14.2	7.2

Fig. 6 Mechanical properties of NR and the NR/TiO₂-CNTs composites: elastic modulus (a), tensile strength (b), and elongation at break (c).

Table 3 The hardness, rebound resilience, abrasion, and compression properties of the composites

Samples	NR	NR/1TiO ₂ -CNTs	NR/2TiO ₂ -CNTs	NR/3TiO ₂ -CNTs	NR/5TiO ₂ -CNTs
Abrasion index (%)	132.5 ± 31.1	129.6 ± 10.2	125.5 ± 2.8	143.1 ± 15.7	158.6 ± 31.6
rebound resilience (%)	62.3 ± 0.9	65.9 ± 0.5	66.9 ± 0.2	71.2 ± 1.2	71.5 ± 0.5
Compression recovery ratio (%)	59.9 ± 4.2	56.1 ± 0.8	63.1 ± 2.9	60.3 ± 3.7	59.3 ± 1.6
Hardness (HA)	36.6 ± 1.2	39.2 ± 0.8	40.2 ± 2.1	40.9 ± 2.3	40.6 ± 1.5

the TiO₂-CNTs. At 700 °C, the residual mass of the NR/TiO₂-CNTs containing 1–5 phr TiO₂-CNTs is higher than that of NR, which should be due to the higher residual mass of TiO₂-CNTs than that of NR. In addition, the decomposition rates of the NR/TiO₂-CNTs composites at the maximum decomposition temperature have no apparent change compared with that of NR. In air atmosphere, both the NR/TiO₂-CNTs composite and NR show two decomposition stages. For them, the additional decomposition at about 550 °C is ascribed to the change in the hydrocarbons.^{7,22,23} However, both the NR/TiO₂-CNTs composites and NR show no an apparent difference in the thermal stability in this case.

3.4. Mechanical properties of the NR/TiO₂-CNTs composites

The elastic modulus at break, tensile strength, and elongation at break for the NR and NR/TiO₂-CNT composites are shown in Fig. 6. Basically, these properties for all the NR/TiO₂-CNTs composites containing 1, 2, 3, and 5 phr TiO₂-CNTs are superior to those of the NR composites and all of them firstly increase to a maximum value and then decrease, showing a similar change trend on raising the content of the TiO₂-CNTs. For the NR

composite, the elastic modulus, tensile strength, and elongation at break are 2.9 MPa, 19.2 MPa, and 1395.1%, respectively. When the content of TiO₂-CNTs is 3 phr, these parameters for NR/3TiO₂-CNTs reach 4.1 MPa, 32.0 MPa, and 1604.1%, respectively, which correspondingly increased by 41.4%, 66.7%, and 15.0%. In this case, the tensile strength of the NR/3TiO₂-CNTs almost reaches the maximum value, which is equivalent to the strength of 50 phr carbon black-filled NR composite (about 32.0 MPa in our experiment). The elongation at break for the NR/1TiO₂-CNTs and the elastic modulus for the NR/5TiO₂-CNTs are slightly higher than the corresponding values of other NR/TiO₂-CNTs composites in the TiO₂-CNTs range from 0 to 9 phr, respectively. Clearly, the TiO₂-CNTs is an ideal reinforcing agent for NR and a small amount of TiO₂-CNTs may significantly enhance the mechanical properties of NR.

3.5. Rebound resilience, abrasion, compression properties, and hardness

Table 3 shows that the hardness and rebound resilience of NR increase slightly after the incorporation of the TiO₂-CNTs. When the content of TiO₂-CNTs is 5 phr, the hardness and rebound resilience of NR/5TiO₂-CNTs are raised to 40.6 HA and 71.5%, respectively. For the compression recovery ratio, there is no apparent change on increasing the TiO₂-CNTs from 1 to 5 phr compared with that of NR. As for the abrasion property, it can be found that the abrasion indexes of the NR composites show a slight fluctuation in comparison with that of NR when there is only 1 and 2 phr TiO₂-CNTs. On increasing the TiO₂-CNTs to 3 and 5 phr, the abrasion indexes of NR/3TiO₂-CNTs reach 143.1 and 158.6%, respectively. Clearly, the TiO₂-CNTs have different influences on the rebound resilience, abrasion, compression properties, and hardness of NR.

3.6. The vulcanization properties of the NR/TiO₂-CNTs composites

The vulcanization properties of different NR/TiO₂-CNTs composites are shown in Fig. 7. Compared to the NR composite, the addition of TiO₂-CNTs increases the torque of the composite to some extent, suggesting that TiO₂-CNTs efficiently increased the

Fig. 7 Vulcanization properties of different NR/TiO₂-CNTs composites.Fig. 8 The maximum temperatures at the surfaces of NR (a), NR/1TiO₂-CNTs (b), NR/2TiO₂-CNTs (c), NR/3TiO₂-CNTs (d), and NR/5TiO₂-CNTs (e) during the friction test.

crosslink density of the composites. Here, the increased crosslink density is mainly ascribed to the physical crosslinking caused by the nanoparticles. When the addition amount of TiO_2 -CNTs is 3 or 5 phr, the torque of the composite decreases slightly, which should be attributed to the aggregation of TiO_2 -CNTs in the matrix.

3.7. Stability of the NR/ TiO_2 -CNTs composites under extreme friction condition

The temperature change at the friction surface of the NR/ TiO_2 -CNTs composites was observed by an infrared thermal imager. Fig. 8 shows the highest temperature of the friction surface of the NR/ TiO_2 -CNTs composites in 30 s during the friction test. Here, it should be noted that the friction test was performed in

the presence of 50 phr carbon black in the NR composite. The maximum temperature at the friction surfaces of NR and NR/1 TiO_2 -CNTs are 246 °C but the maximum temperatures at the friction surfaces of NR/3 TiO_2 -CNTs and NR/5 TiO_2 -CNTs decrease compared with that of NR, which are 217 °C and 210 °C, respectively, which correspondingly decreased by 29 and 36 °C compared with that at the surface of NR. However, there is no apparent change in the friction time to reach the maximum temperature at the friction surface between NR and the NR/ TiO_2 -CNTs composites. The above experimental results showed that a small amount of TiO_2 -CNTs reduced the temperature peak at the friction surface of NR, which remarkably enhanced the stability of the tread of the aircraft tires when experiencing the extreme friction condition.

Fig. 9 SEM and TEM micrographs of NR and the NR/ TiO_2 -CNTs composites: NR (a and a₁), NR/1 TiO_2 -CNTs (b and b₁), NR/3 TiO_2 -CNTs (c and c₁), NR/5 TiO_2 -CNTs (d and d₁).

Fig. 10 SEM micrographs at the friction surfaces of NR (a₁-a₄), NR/1 TiO_2 -CNTs (b₁-b₄), NR/2 TiO_2 -CNTs (c₁-c₄), NR/3 TiO_2 -CNTs (d₁-d₄), and NR/5 TiO_2 -CNTs (e₁-e₄).

Fig. 11 Confocal microscope pictures of the friction surfaces of NR (a), NR/1TiO₂-CNTs (b), NR/2TiO₂-CNTs (c), NR/3TiO₂-CNTs (d), and NR/5TiO₂-CNTs (e).

Here, a low heat signature was detected on the surface of the NR/TiO₂-CNTs composites, which should mainly be due to the reduction of surface friction or the higher thermal conductivity. Of course, the thermal stability of the NR/TiO₂-CNTs composites also plays a role in decreasing the surface temperature.

3.8. Mechanism of mechanical enhancement and the improved stability

First, the brittle-fractured surfaces of the NR and NR/TiO₂-CNTs composites were investigated by SEM, and the result is shown in Fig. 9. When the amount of TiO₂-CNTs is 3 phr, the bulge of a single nanotube can be seen locally, which should be caused by the insertion of the nanotubes. At 3 phr TiO₂-CNTs in NR, micro-aggregation of the nanotubes appears. In order to more directly observe the dispersion of TiO₂-CNTs in the NR substrate, TEM was performed for NR and the NR/TiO₂-CNTs composites. For NR, there are some black particles (marked by red ellipse), which should be from insoluble sulfur that is dispersed in the NR substrate. For the composites filled with different amounts of TiO₂-CNTs, nanotubes (marked by blue ellipse) can be clearly seen in the NR matrix. When the loading amount of TiO₂-CNTs is 1 phr, the nanotubes do not agglomerate obviously and the dispersion of the TiO₂-CNTs is very uniform. On increasing the TiO₂-CNTs concentration to 3 phr, a slight agglomeration of the nanotubes is observed. When the content of TiO₂-CNTs reaches 5 phr, some larger aggregates exist in the NR. These results indicate that it is very easy for TiO₂-CNTs to agglomerate in the NR matrix when the amount of TiO₂-CNTs is higher than 3 phr, which is an important reason that affects the mechanical properties.

Fig. 10 shows the SEM micrographs at the friction surfaces of the NR and NR/TiO₂-CNTs composites after the friction test. The results show that there are obvious cavities at the friction surface of NR and there are some debris at the edge of the cavities. For the NR/1TiO₂-CNTs and NR/2TiO₂-CNTs composites, there are also some cavities and debris at the friction surfaces. However, no cavity or debris can be observed at the friction surface for NR/3TiO₂-CNTs, the friction surface is continuous and dense, showing a toughness characteristic. At 5 phr TiO₂-CNTs, there are a

small number of cracks at the surface of the NR/5TiO₂-CNTs composite. Moreover, some aggregates also exist at the surface, which should be related to the aggregation of the TiO₂-CNTs and is consistent with the SEM result shown in Fig. 9. The analysis of the morphology of the friction surface demonstrated that the introduction of TiO₂-CNTs affected the friction behavior of NR and reduced the damage of friction to the surface of NR, which should be an important reason for the improved stability of the NR/TiO₂-CNTs composites containing a small amount of TiO₂-CNTs.

A confocal microscope was also used to analyze the friction surface of different rubber composites, and the morphologies and roughness data of different friction surfaces are respectively shown in Fig. 11 and Table 4. The result shows that the roughness of the friction surface decreases with the increase in TiO₂-CNTs. When the contents of TiO₂-CNTs are 3 and 5 phr, the roughness data at the corresponding friction surfaces are reduced to 8.2 and 3.8 μm, much lower than that of NR, which must be an important reason for the obvious decrease in the maximum temperature at the friction surfaces of NR/3TiO₂-CNTs and NR/5TiO₂-CNTs.

Fig. 12 shows the EDS result at the friction surfaces of NR and the NR/TiO₂-CNTs composites after the friction test. When TiO₂-CNTs were incorporated into the NR, the relative contents of C, O, and S elements at the friction surface change significantly. The relative content of S element at the friction surface of NR/1TiO₂-CNTs, NR/2TiO₂-CNTs, or NR/3TiO₂-CNTs decreases compared with that of NR, and the relative content of the O element also decreases, while the relative content of C increases in this case. It is worth noting that the relative content of O element at the friction surface of NR/5TiO₂-CNTs is relatively

Table 4 Roughness data at the friction surfaces of the NR/TiO₂-CNTs composites after the friction test

high, which should be caused by the presence of more TiO₂-CNTs at the surface, as illustrated in the SEM results shown in Fig. 9 and 10. On the basis of less O element and more C element at the friction surfaces of NR/1TiO₂-CNTs, NR/2TiO₂-CNTs, and NR/3TiO₂-CNTs composites, it can be concluded that the damage of friction to the crosslinking network of NR was reduced when a small amount of TiO₂-CNTs were incorporated into the NR, further illustrating that a small amount of TiO₂-CNTs promoted the stability of NR under the intensive friction condition.

In order to further study the stability of the NR/TiO₂-CNTs composites, LRS test was used to study the difference in the graphitization degree at the friction surface for NR and the NR/TiO₂-CNTs composites. The result is shown in Fig. 13. For NR,

the I_D/I_G value of the material at the friction surface is 5.85. After the incorporation of 1 phr TiO₂-CNTs, the I_D/I_G value decreases slightly. With the increase in the TiO₂-CNTs, the I_D/I_G value at the surface of the NR/TiO₂-CNTs composites decreases gradually and is greatly reduced to 3.85 when TiO₂-CNTs is 5 phr, which is significantly lower than that of NR, indicating that the TiO₂-CNTs promoted the graphitization degree at the friction surface of NR during the friction test. The graphitization degree at the friction surface can protect the internal substrate more effectively and prevent the erosion of heat and oxygen. Consequently, a small amount of TiO₂-CNTs made a positive contribution to the stability of the NR/TiO₂-CNTs composites by promoting the graphitization degree at the friction surface of NR.

4. Conclusions

The TiO₂-CNTs hybrid was prepared by the sol-gel method in the current work. Different measurements demonstrate that TiO₂-CNTs have a tubular structure, for which the inner tube is CNT and the outer particles are TiO₂. When the TiO₂-CNTs were used to fabricate the NR/TiO₂-CNTs composites, it was found that only 3.0 wt% of TiO₂-CNTs endowed NR with significantly improved tensile strength and elastic modulus, which were 32.0 MPa and 4.1 MPa, respectively, which correspondingly increased by 66.7% and 41.4% compared with that of NR. More importantly, the stability of NR under extreme friction condition was greatly improved. The maximum temperatures at the friction surfaces of NR/3TiO₂-CNTs and NR/5TiO₂-CNTs were greatly reduced by 29 and 36 °C, respectively, compared with that for NR. The mechanisms for the mechanical enhancement of NR and the improved stability of the NR/TiO₂-CNTs composites under extreme friction condition were deeply discussed. All these experimental results demonstrated that the hybridization of both TiO₂ and CNTs may efficiently and simultaneously achieve the mechanical enhancement of natural rubber and its stability under extreme friction condition, and the TiO₂-CNTs have a potential value in the tread material of aircraft tires.
