The detection of  $\text{Al}^{3+}$  and  $\text{Cu}^{2+}$  ions using  
isonicotinohydrazide-based chemosensors and their  
application to live-cell imaging

A novel receptor (3) synthesized from isonicotinic hydrazide and 2,4-dihydroxybenzaldehyde in ethanol demonstrated excellent selectivity and sensitivity towards  $\text{Cu}^{2+}$  ( $1.3 \times 10^4 \text{ M}^{-1}$ ) and  $\text{Al}^{3+}$  ( $K_a$  of  $4.8 \times 10^4 \text{ M}^{-1}$ ). Receptor 3 showed the LOD of 3.0 nM for  $\text{Al}^{3+}$  and LOD of 1.9  $\mu\text{M}$  for  $\text{Cu}^{2+}$ . The quick response, easy-synthesis, and high sensitivity make receptor 3 an ideal sensor for detecting  $\text{Al}^{3+}$  ions in a semi-aqueous medium and living cells.

A new Schiff base receptor (**3**) was synthesized by an equimolar reaction between isonicotinic hydrazide and 2,4-dihydroxybenzaldehyde in ethanol. Receptor **3** demonstrated excellent selectivity and sensitivity towards  $\text{Cu}^{2+}$  ions and  $\text{Al}^{3+}$  ions by UV-vis absorption spectroscopy and fluorescence spectroscopy, respectively. Receptor **3** showed a detectable color change from colorless to yellow with a red-shift ( $\Delta\lambda \approx 70$  nm) in the absorption spectra in the presence of  $\text{Cu}^{2+}$ . In the emission study of **3**,  $\text{Al}^{3+}$  showed significant fluorescent enhancement ( $\lambda_{\text{em}} = 473$  nm) over a wide range of tested metal ions. The quantum yield of receptor **3** ( $\Phi = 0.0021$ ) increases  $\sim 230$  folds in the presence of  $\text{Al}^{3+}$  ions to form receptor **3**· $\text{Al}^{3+}$  complex ( $\Phi = 0.484$ ). Receptor **3** showed high selectivity for  $\text{Al}^{3+}$  with a  $K_a$  of  $4.8 \times 10^4 \text{ M}^{-1}$  and LOD of 3.0 nM. In comparison,  $K_a$  for  $\text{Cu}^{2+}$  was  $1.3 \times 10^4 \text{ M}^{-1}$  and LOD of 1.9  $\mu\text{M}$ . Receptor **3** is an excellent chemosensor for detecting  $\text{Al}^{3+}$  ions as indicated by its nanomolar range LOD. The quick response, easy-synthesis, and high sensitivity make receptor **3** an ideal sensor for detecting  $\text{Al}^{3+}$  ions in a semi-aqueous medium and living cells.

## 1. Introduction

Development of highly specific and sensitive chemosensors has attracted significant interest in detecting bioactive metal ions and toxic metal ions due to their importance in chemical, biological, medical, material, and environmental sciences.<sup>1–4</sup> Development of colorimetric and fluorescence-based detection methods that target precise recognition of bioactive metals such as copper ( $\text{Cu}^{2+}$ ) and aluminum ( $\text{Al}^{3+}$ ) is a topic of high interest among researchers.<sup>5–11</sup>

$\text{Cu}^{2+}$  is the third most abundant heavy metal after  $\text{Fe}^{3+}$  and  $\text{Zn}^{2+}$  in the human body. Several biological processes require  $\text{Cu}^{2+}$  in optimum amounts.<sup>12–15</sup> Enzymes such as tyrosinase, lysyl oxidase, cytochrome *c* oxidase, and superoxide dismutase

require  $\text{Cu}^{2+}$  for redox reactions.<sup>16,17</sup> Even though  $\text{Cu}^{2+}$  is potentially toxic, it is an essential element.<sup>18</sup> The deficiency of  $\text{Cu}^{2+}$  leads to Menkes disease.<sup>19,20</sup> Whereas, the accumulation of  $\text{Cu}^{2+}$  is correlated to the Wilson disease,<sup>21,22</sup> Amyotrophic Lateral Sclerosis,<sup>23,24</sup> and Alzheimer's disease.<sup>25,26</sup> The crucial physiological relevance of  $\text{Cu}^{2+}$  and its associated biomedical insinuations has resulted in substantial attention for the scheming of highly selective and sensitive copper chemosensors.<sup>27</sup>

$\text{Al}^{3+}$  is one of the most abundant biosphere elements at approximately 8% of the total mineral components. The neurotoxicity of  $\text{Al}^{3+}$  has been known to humans for over one hundred years.<sup>28,29</sup>  $\text{Al}^{3+}$  can cause many health issues, including Alzheimer's disease<sup>30</sup> and osteomalacia,<sup>31</sup> and increased risk of breast cancer.<sup>32</sup> The World Health Organization (WHO) recommends 3–10 mg of  $\text{Al}^{3+}$  as an average daily intake. At the same time, the weekly tolerable dietary intake is about 7 mg  $\text{kg}^{-1}$  body weight. Thus, recognizing  $\text{Al}^{3+}$  in life and environmentally significant samples is critical to address.<sup>33,34</sup> The detection of  $\text{Al}^{3+}$  has been challenging compared to other metal ions because of poor spectroscopic characteristics, meager coordination ability, and easy hydration.<sup>35–37</sup> The development of highly sensitive and selective chemosensor for  $\text{Al}^{3+}$  detection is in great demand. Therefore, it is of substantial importance to build receptors for the selective detection of  $\text{Al}^{3+}$ .

According to recent literature, noncyclic receptors containing multiple coordination sites have considerably improved in

the chemosensor design because of their ability to recognize different ionic and neutral molecules.<sup>38–40</sup> Such noncyclic receptors are well known to show interesting coordination properties due to heteroatoms in chelating sites. With this in mind, a Schiff base (receptor **3**, Fig. 1a) was prepared from isonicotinohydrazide and 2,4-dihydroxybenzaldehyde and evaluated as the target receptor for the metal ions. It was hypothesized that N atoms of the  $-\text{CH}=\text{N}-$  bond and the O atom of *ortho*  $-\text{OH}$  in receptor **3** could coordinate with the metal ion to form a stable complex. Herein, we report receptor **3** as a selective chemosensor for  $\text{Cu}^{2+}$  as it showed the distinctive red shift in the absorption maxima but without any fluorescence signal for the complex. Receptor **3** was found to be an excellent fluorescence sensor for  $\text{Al}^{3+}$ , as evident from the chelation-enhanced fluorescence (CHEF) effect. The application of receptor **3** in fluorescence imaging was evaluated by confocal fluorescence microscopy in A549 cells, proving receptor **3** as a convenient tool for tracking  $\text{Al}^{3+}$  *in vivo*.

## 2. Material and methods

### 2.1 Materials and instrumentation

All reagents were purchased from Sigma-Aldrich and were used as received unless stated otherwise. The reaction was carried out under an inert atmosphere (Argon gas) and monitoring the reaction using thin-layer chromatography (TLC) to confirm the formation of the product. The developed plates were visualized under UV light (254 nm). The synthesized compound was characterized by  $^1\text{H}$  and  $^{13}\text{C}$  NMR on a Jeol FT-NMR spectrometer (400 MHz; JEOL, Japan) in  $\text{DMSO}-d_6$ . The chemical shifts ( $\delta$  ppm) and the coupling constants ( $J$  Hz) are reported. UV-visible spectra were recorded on a Shimadzu UV-24500 (Shimadzu, Japan) in the range of 200–600 nm at room temperature using a quartz cuvette of 1 cm optical path length. Fluorescence emission spectra were measured on an Agilent Cary Eclipse fluorescence spectrophotometer (Agilent Technologies, USA). FT-IR spectra were recorded on a Nicolet iS5 FT-IR (ThermoScientific) spectrometer in the range of 400–4000  $\text{cm}^{-1}$  using KBr pellets. The JMS-700 MStation Mass Spectrometer (JEOL, Japan) was used for recording the high-resolution mass spectra of receptor **3**. The mass spectra of  $3\cdot\text{Al}^{3+}$  complex were obtained by matrix-assisted laser deposition/ionization (time-of-flight), MALDI-TOF mass spectrometry on a Bruker Autoflex speed TOF/TOF spectrometer (Bruker Daltonics, Bremen, Germany). X-ray analysis was performed using a Bruker AXS D8 Quest CMOS diffractometer (Bruker, USA). The microplate reader was Spectramax Plus 384 (Molecular Devices, USA),

and the fluorescent microscope Zeiss-ScopeA1 (Germany) was used in this study.

### 2.2 Synthesis of receptor 3

Isonicotinohydrazide (0.198 g, 1.0 mmol) and 2,4-dihydroxybenzaldehyde (0.200 g, 1.0 mmol) were reacted in ethanol (25 mL) at room temperature until the completion of the reaction (5 h). The yellow color solid obtained was filtered and dried. Then, the obtained yellow colored crud product was recrystallization from ethanol (yield = 90%).  $^1\text{H}$  NMR (400 MHz,  $\text{DMSO}-d_6$ ):  $\delta$  6.36 (d, 2H, Ar-H), 7.36 (s, 1H, Ar-H), 7.82 (d, 2H, Ar-H), 8.54 (s, 1H,  $\text{CH}=\text{N}$ ), 8.77 (d, 2H, Ar-H), 10.08 (s, 1H, Ar-OH), 11.29 (s, 1H, NH), 12.14 (s, 1H, Ar-OH);  $^{13}\text{C}$  NMR (100 MHz,  $\text{DMSO}-d_6$ ):  $\delta$  102.61, 107.84, 110.40, 121.43, 131.20, 140.07, 150.29, 159.49, 161; mass: expt.  $m/z$  = 258.0870 ( $\text{C}_{13}\text{H}_{11}\text{N}_3\text{O}_3$  [ $\text{M} + \text{H}$ ]), calc.  $m/z$  = 257.245.

### 2.3 UV-vis and fluorescence spectral measurements

All stock and working solutions were prepared using double distilled water and spectroscopic grade DMSO. A stock solution of receptor **3** ( $1 \times 10^{-3}$  M) was prepared in DMSO, and the corresponding working solutions ( $10 \times 10^{-6}$  M) were prepared simply by diluting with DMSO. Similarly, stock solutions of cations ( $1 \times 10^{-2}$  M) were prepared in double-distilled water, and the corresponding working solutions ( $1 \times 10^{-3}$  M) were prepared by diluting with water. The UV-visible absorption and emission spectra of the receptor **3** ( $10 \times 10^{-6}$  M) dissolved in DMSO were recorded by adding the aqueous solution of various metal ions ( $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Ag}^+$ ,  $\text{Cs}^+$ ,  $\text{Sr}^{2+}$ ,  $\text{Ca}^{2+}$ ,  $\text{Co}^{2+}$ ,  $\text{Cu}^{2+}$ ,  $\text{Pd}^{2+}$ ,  $\text{Mn}^{2+}$ ,  $\text{Mg}^{2+}$ ,  $\text{Ba}^{2+}$ ,  $\text{Ni}^{2+}$ ,  $\text{Zn}^{2+}$ ,  $\text{Cd}^{2+}$ ,  $\text{Pb}^{2+}$ ,  $\text{Al}^{3+}$ ,  $\text{Cr}^{3+}$ ,  $\text{Fe}^{3+}$ ,  $\text{Fe}^{2+}$ ) to examine the selectivity at room temperatures (298 K). For the sensitivity study, UV-visible absorption and emission titration experiments were performed through a stepwise addition of four equivalents of metals ( $1 \times 10^{-3}$  M) to a solution of receptor **3** ( $10 \times 10^{-6}$  M) in DMSO. The absorbance intensity and emission intensity were recorded in the range of 200–600 nm and 360–600 nm, respectively, alongside a reagent blank. Receptor **3** showed selectivity for detecting  $\text{Cu}^{2+}$  in the absorption titrations and detecting  $\text{Al}^{3+}$  in the fluorescence titrations. The binding stoichiometry of receptor **3** with  $\text{Cu}^{2+}$  ion (UV-visible absorption spectroscopy) and  $\text{Al}^{3+}$  ion (fluorescence spectroscopy) were investigated by Job's plot method. A receptor **3** was titrated with successive addition of  $\text{Cu}^{2+}$  or  $\text{Al}^{3+}$  (1  $\mu\text{L}$ ,  $1.0 \times 10^{-3}$  M) in water to a receptor **3** (1.0 mL) solution in DMSO. The collected data were processed using the Benesi-Hildebrand equation<sup>41</sup> to determine the association constant ( $K_a$ ) of analyte  $\text{Cu}^{2+}$  and  $\text{Al}^{3+}$  ion with receptor **3**. The absorbance changes at 413 nm were used alongside a reagent blank for the

detection of  $\text{Cu}^{2+}$  ions. The fluorescence intensity was recorded at  $\lambda_{\text{ex}}/\lambda_{\text{em}} = 343/473$  nm alongside a reagent blank with the excitation and emission slits set to 5.0 nm. The limit of detection (LOD) was estimated by applying the IUPAC recommended equation,  $\text{LOD} = 3\sigma/\text{slope}$ .<sup>42</sup> Where  $\sigma$  is the standard deviation of ( $n = 10$ ) blank samples and the slope is the slope for calibration curves.

## 2.4 Crystal growth for single X-ray crystallography

The single crystals of receptor **3** were obtained by slow diffusion of ethanol in DMSO. However, several attempts to obtain the single crystals of receptor **3** and  $\text{Al}^{3+}$  complex (**3-Al**<sup>3+</sup>), receptor **3** and  $\text{Cu}^{2+}$  complex (**3-Cu**<sup>2+</sup>) were unsuccessful. A suitable single crystal was carefully mounted for X-ray crystallography with the help of a trace of Fomblin oil on a Mitegen micromesh mount. Then it was transferred to the goniometer head with a fixed chi angle, a molybdenum  $K_{\alpha}$  wavelength fine focus sealed X-ray tube ( $\lambda = 0.71073$ ), a single crystal curved graphite incident beam monochromator, a Photon100 CMOS area detector, and an Oxford Cryosystems low-temperature device. X-ray diffraction data were collected at 150 K using  $\omega$  and  $\phi$  scans to a maximum resolution of  $\theta = 33.221^\circ$ . Data reduction, scaling, and absorption corrections were performed using SAINT (Bruker, V8.38A). The final completeness is 89.00% out of  $33.221^\circ$  in  $\theta$ . Multi-scan absorption correction was performed using SADABS 2016/2.<sup>43</sup> The absorption coefficient  $\mu$  of this material was  $0.107 \text{ mm}^{-1}$  at this wavelength ( $\lambda = 0.71073 \text{ \AA}$ ). The space group was determined based on systematic absences using XPREP<sup>44</sup> as *Pna*2<sub>1</sub>. The structure was solved using direct methods with ShelXS-97 and refined by full-matrix least-squares on  $F^2$  using ShelXL-2018/3 and the graphical interface ShelXLE (Rev937).<sup>45</sup> All non-hydrogen atoms were refined anisotropically. Hydrogen atom positions were calculated geometrically and improved using a riding model. Mercury, PyMol, and POVRay were utilized for molecular measurements and molecular visualization.<sup>46</sup>

## 2.5 Effect of pH on the detection of $\text{Al}^{3+}$ and reversibility of receptor **3**

The effect of pH (pH = 2–12) on receptor **3** was examined by fluorescence spectroscopy both in the absence and presence of  $\text{Al}^{3+}$  ions. The pH was adjusted by adding perchloric acid and tetrabutylammonium hydroxide in the HEPES buffered system. Reversibility is a critical aspect of the fluorescent recognition process. Hence, we examined the reversibility of receptor **3** in the presence of ethylenediaminetetraacetic acid disodium salt ( $\text{EDTANa}_2$ ). For the reversibility study,  $\text{EDTANa}_2$  (4 equiv.) was added to the solution containing receptor **3-Al**<sup>3+</sup> complex obtained by adding  $\text{Al}^{3+}$  at a 1 : 4 mole ratio. The reversibility was recorded by alternate additions of  $\text{Al}^{3+}$  (4 equiv.) and  $\text{EDTANa}_2$  (4 equiv.).

## 2.6 Determination of quantum yield of receptor **3** and receptor **3-Al**<sup>3+</sup> complex

Quantum yields ( $\Phi$ ) of receptor **3** and its complexes with  $\text{Al}^{3+}$  were measured using the following formula.

$$\Phi_{\text{sample}} = \left\{ \frac{(\text{OD}_{\text{standard}} \times A_{\text{sample}} \times \eta_{\text{sample}}^2)}{(\text{OD}_{\text{sample}} \times A_{\text{standard}} \times \eta_{\text{standard}}^2)} \right\} \times \Phi_{\text{standard}}$$

where  $A$  is the area under the emission spectral curve, OD is the compound's optical density at the excitation wavelength, and  $\eta$  is the refractive index of the solvent. The quantum yield of receptor **3** and its complexes with  $\text{Al}^{3+}$  was determined using  $\beta$ -carboline ( $\Phi = 0.570$ ) as the standard.<sup>47</sup>

## 2.7 Cell culture studies

The cytotoxicity assay (MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay) and cell imaging study of receptor **3**,  $\text{Al}^{3+}$ , and  $\text{Al}^{3+}$  combined with receptor **3** was conducted using A549 cells (colorectal carcinoma cell line). The A549 cells were procured from the Korea cell line bank, Seoul, South Korea. Dulbecco Modified Eagle Medium (DMEM), fetal bovine serum (FBS), trypsin, 3-(4,5-dimethyl thiazol-2-yl)-2,5-diphenyl tetrazolium bromide was procured from Thermo Fisher Scientific, USA. DMSO was procured from Biosesang, Korea. Cell culture plates and glass coverslips were procured from SPL Life Sciences, Korea. A549 cells were grown in an incubator at  $37^\circ\text{C}$  and 5%  $\text{CO}_2$  using DMEM media containing 2 mM glutamine and 10% FBS. Cells were trypsinized for seeding at 70–90% of cell confluency.

## 2.8 Cytotoxicity assay and cell imaging

About 2000 A549 cells per well were seeded in 96-well plates. After 24 h, the media containing receptor **3**,  $\text{Al}^{3+}$  ion, and receptor **3** with  $\text{Al}^{3+}$  (1, 10, 25, and 50  $\mu\text{M}$ ) were added to the wells and incubated for another 24 h. Control wells were treated with equivalent volumes of dimethyl sulfoxide (DMSO). 200  $\mu\text{L}$  of fresh media containing MTT solution and incubated for four hours at  $37^\circ\text{C}$ . The absorbance was recorded at 570 nm to evaluate the cell viability. Each experiment was executed three times. The data analysis was performed using the Origin software.

For cell imaging, A549 cells were seeded separately on poly-L-lysine coated 14 mm coverslips in 6 well plates and allowed to grow for 24 h. For cell imaging control experiments, 10  $\mu\text{M}$  of  $\text{Al}^{3+}$  ion and 10  $\mu\text{M}$  of receptor **3** were incubated separately for 30 min at  $37^\circ\text{C}$  and 5%  $\text{CO}_2$  in the dark. For cell imaging of receptor **3** and  $\text{Al}^{3+}$  complex, 10  $\mu\text{M}$  of  $\text{Al}^{3+}$  ion was incubated separately for 30 min. The media was then replaced with 10  $\mu\text{M}$  of receptor **3** and incubated for an additional 30 min. The cells were washed with PBS buffer (pH = 7.4), followed by fixing with 2% paraformaldehyde for 30 min after removing the media. Coverslip was mounted on a glass slide, and imaging was performed under a fluorescence microscope (Zeiss-ScopeA1, Germany). Images were taken through a green channel.

# 3. Results and discussion

## 3.1 Synthesis of receptor **3**

The Schiff base (*E*)-*N'*-(2,4-dihydroxybenzylidene)isonicotinohydrazide (receptor **3**) was synthesized with a slight modification of the reported<sup>48</sup> method through a direct reaction between isonicotinohydrazide and 2,4-dihydroxybenzaldehyde (Fig. 1a) in ethanol with stirring and refluxing for 5 h. The molecular structure of

receptor **3** was characterized using various spectral techniques (FT-IR,  $^1\text{H}$  NMR,  $^{13}\text{C}$  NMR, and Mass), data (ESI,† Fig. S1–S3) and finally confirmed by single-crystal X-ray crystallography (Fig. 1b). The crystallographic data, selected bond parameters, and hydrogen-bond parameters are presented in Tables S1, S2 and S3, respectively. The CIF file for receptor **3** was placed in the Cambridge Structure Database (CCDC 2051947†). The orange-colored crystal ( $0.55 \times 0.42 \times 0.05 \text{ mm}^3$ ) of receptor **3** demonstrated an orthorhombic system having a  $Pna2_1$  space group within the unit cell. The ORTEP diagram with numbering and packing diagram is shown in Fig. 1b. The receptor **3** in its free form displays the molecular association *via* intramolecular hydrogen bonding between the phenolic hydroxyl to imine nitrogen. Receptor **3** shows an intramolecular hydrogen bond ( $\text{O}(1)\text{--H}\cdots\text{N}(1)$ ) with a distance of  $1.92(3) \text{ \AA}$  and a bond angle of  $150(2)^\circ$ , which is in the expected range of such hydrogen bonds. Receptor **3** undergoes a solvent-assisted keto tautomerization suitable for the intramolecular charge transfer (ICT) process.<sup>49</sup> The fluorescence intensity enhancement of receptor **3** in the presence of  $\text{Al}^{3+}$  is attributed to the ICT process.

### 3.2 Determination of selectivity of receptor **3** as a chemosensor for metal ions

The selectivity of receptor **3** for cation detection was investigated using the UV-visible absorption and fluorescence spectroscopy. The UV-vis absorption spectra of receptor **3** ( $10 \times 10^{-6} \text{ M}$ , in DMSO) were recorded in the absence and presence of 4 equivalents of various metal ions, such as  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Ag}^+$ ,  $\text{Cs}^+$ ,  $\text{Sr}^{2+}$ ,  $\text{Ca}^{2+}$ ,  $\text{Co}^{2+}$ ,  $\text{Cu}^{2+}$ ,  $\text{Pd}^{2+}$ ,  $\text{Mn}^{2+}$ ,  $\text{Mg}^{2+}$ ,  $\text{Ba}^{2+}$ ,  $\text{Ni}^{2+}$ ,  $\text{Zn}^{2+}$ ,  $\text{Cd}^{2+}$ ,  $\text{Pb}^{2+}$ ,  $\text{Al}^{3+}$ ,  $\text{Cr}^{3+}$ ,  $\text{Fe}^{3+}$ ,  $\text{Fe}^{2+}$  ( $1 \times 10^{-3} \text{ M}$ , in  $\text{H}_2\text{O}$ ).

Receptor **3** showed an absorption band at  $343 \text{ nm}$ , most likely due to the  $\pi \rightarrow \pi^*$  transition (Fig. 2a). Upon addition of  $\text{Cu}^{2+}$  ions, the absorption band at  $343 \text{ nm}$  was red-shifted to  $413 \text{ nm}$  ( $\Delta\lambda \approx 70 \text{ nm}$ ), indicating that receptor **3** has a higher binding affinity towards  $\text{Cu}^{2+}$  ions than other surveyed metal ions. Receptor **3** showed two additional shoulder peaks at  $428 \text{ nm}$  and  $475 \text{ nm}$  to the major peak at  $413 \text{ nm}$ . In the presence of other metal ions, receptor **3** showed either no change or moderate decrease in the absorption intensity

relative to the receptor. These results indicated the intramolecular charge transfer (ICT) character of the synthesized receptor **3** by recognizing  $\text{Cu}^{2+}$  ions through imine-N, amide carbonyl, and hydroxyl groups.<sup>50</sup> The push-pull character of the ICT state due to multiple coordination resulted in a red-shift ( $\Delta\lambda \approx 70 \text{ nm}$ ). These results indicated that receptor **3** shows selectivity for  $\text{Cu}^{2+}$  ions.

The fluorescence emission spectra of receptor **3** ( $10 \times 10^{-6} \text{ M}$ , in DMSO) were recorded in the absence and presence of 4 equivalents of various metal ions, such as  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Ag}^+$ ,  $\text{Cs}^+$ ,  $\text{Sr}^{2+}$ ,  $\text{Ca}^{2+}$ ,  $\text{Co}^{2+}$ ,  $\text{Cu}^{2+}$ ,  $\text{Pd}^{2+}$ ,  $\text{Mn}^{2+}$ ,  $\text{Mg}^{2+}$ ,  $\text{Ba}^{2+}$ ,  $\text{Ni}^{2+}$ ,  $\text{Zn}^{2+}$ ,  $\text{Cd}^{2+}$ ,  $\text{Pb}^{2+}$ ,  $\text{Al}^{3+}$ ,  $\text{Cr}^{3+}$ ,  $\text{Fe}^{3+}$ ,  $\text{Fe}^{2+}$  ( $1 \times 10^{-3} \text{ M}$ , in  $\text{H}_2\text{O}$ ). Receptor **3** showed weak fluorescence emission at  $473 \text{ nm}$  upon excitation at  $343 \text{ nm}$ . Fascinatingly, fluorescence was remarkably enhanced ( $\sim 430$ -folds) in the presence of  $\text{Al}^{3+}$  ions (Fig. 2b). Interestingly, there was no change in the emission performance of receptor **3** in the presence of other cations, including  $\text{Cu}^{2+}$ . The increase in fluorescence emission intensity was due to the azomethine group of receptor **3**. Receptor **3** is reducibly fluorescent due to the  $\text{C}=\text{N}$  double bond's isomerization at the excited state and the excited-state proton transfer (ESPT). The ESPT involves the phenolic proton of the substituted dihydroxyl moieties of salicylaldehyde in receptor **3**. Upon stable chelation with  $\text{Al}^{3+}$ , the  $\text{C}=\text{N}$  isomerization is inhibited. The coordination of receptor **3** with the  $\text{Al}^{3+}$  prohibits the ESPT process, as indicated by the fluorescence enhancement.<sup>51–53</sup>

### 3.3 Binding mechanism and association constant

Job's plot was used to determine the binding stoichiometry of receptor **3** with  $\text{Cu}^{2+}$  ions (UV-visible absorption spectroscopy) and  $\text{Al}^{3+}$  ions (fluorescence spectroscopy). The molar ratio of metal ions was changed from 0.1 to 1.0 by keeping the total concentration of receptor **3** and  $\text{Cu}^{2+}$  ions at  $10 \times 10^{-6} \text{ M}$ . The absorption maxima ( $\lambda = 413 \text{ nm}$ ) was observed when the molar ratio of the receptor **3** to  $\text{Cu}^{2+}$  was 0.33, indicating the formation of a  $2:1$  **3**· $\text{Cu}^{2+}$  complex (Fig. S4a, ESI†). Similarly, the change in fluorescence intensity ( $\lambda_{\text{ex}} = 343 \text{ nm}$ ,  $\lambda_{\text{em}} = 473 \text{ nm}$ ) was used to determine the binding stoichiometry of receptor **3**

Fig. 2 (a) Changes in UV-vis absorption spectra and (b) fluorescence intensity ( $\lambda_{\text{ex}} = 343 \text{ nm}$ ,  $\lambda_{\text{em}} = 473 \text{ nm}$ ) of receptor **3** ( $10 \times 10^{-6} \text{ M}$ ) upon the addition of 4 equivalents of different metal ions ( $1 \times 10^{-3} \text{ M}$ , in  $\text{H}_2\text{O}$ ). Inset shows the color change of the solutions from colorless to pale green and fluorescence 'turn-on' effect.

Fig. 3 FT-IR spectra of (a) **3**·Cu<sup>2+</sup> complex and (b) **3**·Al<sup>3+</sup> complex recorded using the reflectance technique (4000–400 cm<sup>−1</sup>).

with Al<sup>3+</sup>. The molar ratio of Al<sup>3+</sup> was changed from 0.1 to 1.0 by keeping the total concentration of receptor **3**, and Al<sup>3+</sup> ions at  $10 \times 10^{-6}$  M. The emission maxima ( $\lambda = 473$  nm) was observed when the molar ratio of the receptor **3** to Al<sup>3+</sup> was 0.33, indicating the formation of a 2:1 **3**·Al<sup>3+</sup> complex (Fig. S4b, ESI†). The complexes **3**·Cu<sup>2+</sup> and **3**·Al<sup>3+</sup> were obtained by refluxing four equivalents of Cu<sup>2+</sup> and Al<sup>3+</sup> with receptor **3** in an ethanolic solution. To ascertain the formation of receptor **3**·Cu<sup>2+</sup> complex and **3**·Al<sup>3+</sup> complex, we compared FT-IR spectra for receptor **3** with that of respective complexes, as shown in Fig. 3.

The FT-IR spectrum of receptor **3** (Fig. 3a) demonstrated signals at 3436.05, 3224.39 (amide), 3086.99 (intramolecular bonded O–H), and 1647.39 (imine) cm<sup>−1</sup>. For the receptor **3**·Cu<sup>2+</sup> complex, the FT-IR spectrum demonstrated a broad signal at 3422.06 (amide), no frequency for intramolecular bonded O–H, and 1621.84 (imine) cm<sup>−1</sup>. These results indicate that receptor **3** forms a stable complex with Cu<sup>2+</sup>. Similarly, the FT-IR spectrum of receptor **3**·Al<sup>3+</sup> complex demonstrated a broad signal at 3430.74 (amide), no frequency for intramolecular bonded O–H, and 1623.77 (imine) cm<sup>−1</sup>. The FT-IR spectrum shifts in the **3**·Cu<sup>2+</sup> and **3**·Al<sup>3+</sup> complexes compared to the receptor **3**, confirming the involvement of imine and amide groups in the complexation process.

As shown in Fig. 4, the <sup>1</sup>H NMR titration experiment was conducted using the mixture of 0.5% D<sub>2</sub>O–d<sub>2</sub> in DMSO–d<sub>6</sub>. The <sup>1</sup>H NMR of receptor **3** demonstrated sharp peaks at  $\delta_{\text{H}}$  12.12 (amide N–H),  $\delta_{\text{H}}$  11.25, and  $\delta_{\text{H}}$  10.01 (phenolic –OH). The signals for one N–H proton and two –OH protons gradually disappeared upon increasing the amount of Al<sup>3+</sup> ions (0–1 equiv.). However, there was no significant change in the peak corresponding to imine C–H ( $\delta_{\text{H}}$  8.52). These results indicate that the amide group, imine group, and phenolic moiety of receptor **3** take part in the complexation with Al<sup>3+</sup> ions. Further, the MALDI-TOF mass spectrum of receptor **3**·Al<sup>3+</sup> complex showed a signal at an  $m/z$  value of 544.129 and 561.133 (Fig. S5, ESI†). These results rationalize the formation of the 2:1 complexation pattern for the **3**·Al<sup>3+</sup> complex. The paramagnetic property of Cu<sup>2+</sup> results in the peak broadening in proton NMR spectra. Thus, the binding process of receptor **3** with Cu<sup>2+</sup> could not be monitored by NMR studies.<sup>54</sup>

Fig. 4 <sup>1</sup>H NMR spectral changes of receptor **3** in the mixture of 0.5% D<sub>2</sub>O–d<sub>2</sub> in DMSO–d<sub>6</sub>, (a) **3** + Al<sup>3+</sup> (0 equiv.), (b) **3** + Al<sup>3+</sup> (0.25 equiv.), (c) **3** + Al<sup>3+</sup> (0.5 equiv.), (d) **3** + Al<sup>3+</sup> (1 equiv.).

The association constants ( $K_a$ ) of Cu<sup>2+</sup> (UV-visible absorption spectroscopy) and Al<sup>3+</sup> (fluorescence spectroscopy) complexes with receptor **3** were determined by Benesi–Hildebrand equations (eqn (S1) and (S2), ESI†). As shown in Fig. 5a, the receptor **3** (1.0 mL,  $10 \times 10^{-6}$  M) in DMSO was titrated with successive addition of Cu<sup>2+</sup> (0–20  $\mu$ L in H<sub>2</sub>O,  $c = 10 \times 10^{-4}$  M) to measure the association constant ( $K_a$ ). The absorbance values at absorption maxima ( $\lambda = 413$  nm) were processed using the Benesi–Hildebrand equation (eqn (S1), ESI†) to obtain the binding curve (Fig. S6a, ESI†). The  $K_a$  value for the complexation of Cu<sup>2+</sup> with receptor **3** was  $1.3 \times 10^4$  M<sup>−1</sup>.

As shown in Fig. 5b, receptor **3** (1.0 mL,  $10 \times 10^{-6}$  M) in DMSO was titrated with successive addition of Al<sup>3+</sup> (0–20  $\mu$ L in H<sub>2</sub>O,  $c = 10 \times 10^{-4}$  M). The changes in fluorescence intensity ( $\lambda_{\text{ex}} = 343$  nm,  $\lambda_{\text{em}} = 473$  nm) were used to determine the  $K_a$  value by plotting the binding curve (Fig. S6b, ESI†) according to the Benesi–Hildebrand equation (eqn (S2), ESI†). The  $K_a$  value for the complexation of Al<sup>3+</sup> with receptor **3** was  $4.8 \times 10^4$  M<sup>−1</sup>. The binding affinity of Al<sup>3+</sup> for receptor **3** is 4-fold higher than that of Cu<sup>2+</sup> ions.

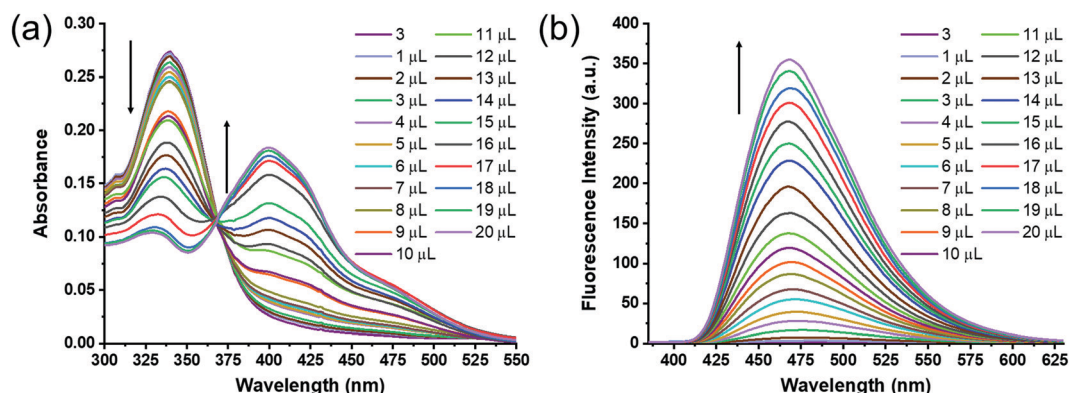

Fig. 5 Changes in (a) UV-vis absorption spectra and (b) fluorescence spectra ( $\lambda_{\text{ex}} = 343$  nm,  $\lambda_{\text{em}} = 473$  nm) of receptor **3** (in 1 mL DMSO,  $10 \times 10^{-6}$  M) up on successive addition of  $\text{Cu}^{2+}$  (0 to 20  $\mu\text{L}$  in  $\text{H}_2\text{O}$ ,  $c = 10 \times 10^{-4}$  M), and  $\text{Al}^{3+}$  (0 to 20  $\mu\text{L}$  in  $\text{H}_2\text{O}$ ,  $c = 10 \times 10^{-4}$  M), respectively.

Computational studies were conducted by applying the density functional theory (DFT) using Gaussian 09. The molecular geometries of the singlet ground state of receptor **3**, **3**· $\text{Cu}^{2+}$  complex, and **3**· $\text{Al}^{3+}$  complex were optimized using hybrid B3LYP functions with a 6-31G++(d,p) (C, H, N, O) and LANL2DZ (Cu, Al) basis sets.<sup>55</sup> The HOMO, LUMO results, information for bond length, and bond angles were obtained using Avogadro 1.2.0.<sup>56</sup> The 3D structures of the **3**· $\text{Cu}^{2+}$  and **3**· $\text{Al}^{3+}$  complexes were calculated by the DFT method using the 2:1 binding stoichiometry between receptor **3** and respective ions. The DFT computed structure of receptor **3** and its complexes are presented in Fig. S7 (ESI<sup>†</sup>). The LUMO–HOMO bandgap ( $\Delta E$  (eV) =  $E_{\text{LUMO}} - E_{\text{HOMO}}$ ) for receptor **3** was found to be 0.293.

In contrast, the LUMO–HOMO bandgap for **3**· $\text{Cu}^{2+}$  and **3**· $\text{Al}^{3+}$  complexes were 0.279 and 0.078, respectively. These results provided the basis for ascertaining the ICT between receptor **3** and  $\text{Cu}^{2+}$  and  $\text{Al}^{3+}$  ions. Comparing the electron densities of the HOMO and LUMO of receptor **3** with the **3**· $\text{Cu}^{2+}$  complex supported the charge transfer occurring between the receptor and metal ions that further lowered the bandgap. The lowering of the bandgap upon complexation supported the red-shift of the absorbance of receptor **3** upon the addition of  $\text{Cu}^{2+}$ . On the contrary, the significant decrease in the LUMO–HOMO bandgap ( $\Delta E = 0.078$ ) indicated the formation of a relatively stable **3**· $\text{Al}^{3+}$  complex as compared to the **3**· $\text{Cu}^{2+}$  complex. The increase in fluorescence enhancement was complemented by a sharp decrease in energy HOMO–LUMO bandgap of the receptor **3**.

#### 3.4 Receptor **3** as a chemosensor for $\text{Cu}^{2+}$ and $\text{Al}^{3+}$ ions

The detection of the target analyte in the presence of possibly competing analytes is a crucial aspect for any compound to be an excellent chemosensor. Therefore, we evaluated the specificity of receptor **3** for  $\text{Cu}^{2+}$  in a competition experiment by recording the absorption ( $\lambda = 413$  nm) receptor **3** in the presence of  $\text{Cu}^{2+}$  (1 equiv.) ion mixed with other cations (4 equiv.). The results of the competition experiments are presented in Fig. S8a (ESI<sup>†</sup>). Similarly, we determined the efficiency of receptor **3** for detecting  $\text{Al}^{3+}$  ions in a competition experiment by recording the fluorescence intensity

( $\lambda_{\text{ex}} = 343$  nm,  $\lambda_{\text{em}} = 473$  nm). As shown in Fig. S8b (ESI<sup>†</sup>), the fluorescence intensity for receptor **3** was measured in the presence of  $\text{Al}^{3+}$  (1 equiv.) ion mixed with other cations (4 equiv.). The coefficient of variation in the change of absorbance and fluorescence intensity for  $\text{Cu}^{2+}$  detection and  $\text{Al}^{3+}$  detection, were below  $\pm 10\%$ , respectively. These results indicate that receptor **3** is a highly valuable chemosensor for detecting  $\text{Cu}^{2+}$  by UV-vis absorption spectroscopy. Moreover, receptor **3** demonstrated its excellence in detecting  $\text{Al}^{3+}$  ions with high specificity by fluorescence spectroscopy. Therefore, the high selectivity and specificity of receptor **3** for  $\text{Cu}^{2+}$  and  $\text{Al}^{3+}$  ions make it an excellent chemosensor for analytical applications. The absorbance ( $\lambda = 413$  nm) and fluorescence intensity ( $\lambda_{\text{ex}} = 343$  nm,  $\lambda_{\text{em}} = 473$  nm) were plotted at various concentrations of  $\text{Cu}^{2+}$  ions and  $\text{Al}^{3+}$  ions, respectively, to obtain the calibration plots (Fig. S9, ESI<sup>†</sup>). The LOD for detecting  $\text{Cu}^{2+}$  ions by UV-vis absorption spectroscopy was 1.86  $\mu\text{M}$ . Whereas, the LOD for the detection of  $\text{Al}^{3+}$  ions by Fluorescence spectroscopy was 3.08 nM. The approximately 600-fold lower sensitivity of receptor **3** for  $\text{Al}^{3+}$  ions compared to  $\text{Cu}^{2+}$  ions was attributed to the  $\sim 4$ -fold higher binding constant for **3**· $\text{Al}^{3+}$  complex. It is important to notice that receptor **3** demonstrated relatively lower detection limits for  $\text{Cu}^{2+}$  and  $\text{Al}^{3+}$  than some of the reported methods presented in Tables S4 and S5 (ESI<sup>†</sup>).

#### 3.5 Effect of pH on the detection of $\text{Al}^{3+}$ and reversibility of receptor **3**

The effect of pH on receptor **3** for detecting  $\text{Al}^{3+}$  ions was tested in the pH range of 2.0–12.0, as shown in Fig. 6a. The emission intensity ( $\lambda_{\text{em}} = 473$  nm) of receptor **3** did not change significantly with the pH change. However, equimolar  $\text{Al}^{3+}$  ions changed the fluorescence intensity of receptor **3**· $\text{Al}^{3+}$  complex considerably with the pH change. The receptor **3**· $\text{Al}^{3+}$  complex's emission intensity was significantly high at pH 2.0–8.0 than pH 9.0–12.0. These results indicate that interactions of  $\text{Al}^{3+}$  ions with receptor **3** are pH dependant. The decrease in emission intensity at higher pH values (9.0–12.0) specifies that the  $\text{Al}^{3+}$  ions are freed from the complex, possibly due to more robust interactions with increased  $-\text{OH}$  levels. Nonetheless, receptor **3**

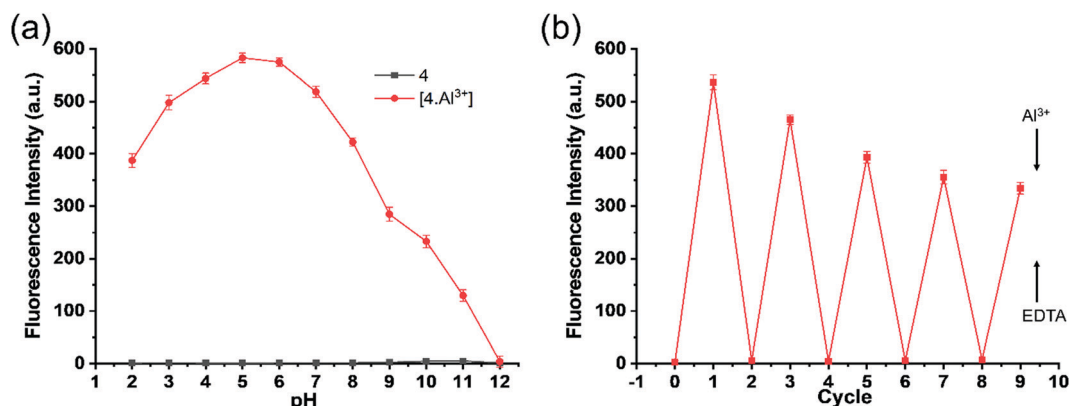

Fig. 6 (a) Changes in the fluorescence intensity of receptor **3** and receptor **3**·Al<sup>3+</sup> complex in a binary mixture of DMSO : HEPES buffer (at various pH values) (9 : 1; v/v), (b) fluorescence intensities ( $\lambda_{\text{ex}} = 343 \text{ nm}$ ,  $\lambda_{\text{em}} = 473 \text{ nm}$ ) of **3**·Al<sup>3+</sup> complex (1 : 1) in the presence of EDTA for many cycles in DMSO.

demonstrated significant fluorescence intensity at pH 5.0–8.0 in the presence of Al<sup>3+</sup> ions, indicating its applicability for the detection of intracellular Al<sup>3+</sup> ions.

It is of a great advantage if a sensor can be reversible and reusable for sensing cations with high selectivity. A literature survey revealed that most of the reported Al<sup>3+</sup> ion sensors are based on chemodosimetry that is typically irreversible.<sup>57</sup> Reversibility test experiments were conducted by alternate additions of Al<sup>3+</sup> ion and EDTA (Fig. 6b) to the solution of receptor **3**. As shown in Fig. 6b, the emission spectra of receptor **3** in the presence of Al<sup>3+</sup> (4 equiv.) showed high emission intensity, which was quenched by EDTANa<sub>2</sub> (6 equiv.) on the solution. However, further addition of Al<sup>3+</sup> (4 equiv.) demonstrated fluorescence signal, but this time slightly lower than the previous cycle. Adding Al<sup>3+</sup> ions (4 equiv.) causes emission enhancement, which can be quenched by adding another portion of EDTANa<sub>2</sub> (6 equiv.). The reversibility of receptor **3** was repetitive, with a slight loss in fluorescence efficiency due to Al<sup>3+</sup>/EDTANa<sub>2</sub> additions. The observed decrease in fluorescence intensity for each cycle results from an excess of EDTANa<sub>2</sub> (6 equiv.) compared to Al<sup>3+</sup> (4 equiv.). This experiment suggests that receptor **3** can act as a likely environmental receptor for Al<sup>3+</sup> detection.

### 3.6 Quantum yield of receptor **3** and receptor **3**·Al<sup>3+</sup> complex

Quantum yields of receptor **3** and **3**·Al<sup>3+</sup> complex were determined using norharmene as a standard. The quantum yield of receptor **3** ( $\Phi = 0.0021$ ) increases ~230 folds in the presence of Al<sup>3+</sup> ions to form receptor **3**·Al<sup>3+</sup> complex ( $\Phi = 0.484$ ).

### 3.7 Application of receptor **3** in cell imaging application for detection of intracellular Al<sup>3+</sup> ions

The complexation-induced fluorescence “turn on” or “turn off” effect is crucial for bio-imaging applications of small molecular probes designed to detect the cationic analyte. Receptor **3** did not show any change in fluorescence intensity upon binding with Cu<sup>2+</sup> ions. However, the fluorescence signal of receptor **3** was increased by a few hundred folds in the presence of Al<sup>3+</sup> ions. Therefore, receptor **3** was used to detect Al<sup>3+</sup> ions in the living A549 cell lines to explore their biological applications. The MTT assay allowed us to estimate the cytotoxicity of receptor **3**, Al<sup>3+</sup>, and receptor **3**·Al<sup>3+</sup> complex after exposure of cells to concentrations of 1, 10, 25, and 50  $\mu\text{M}$  for 24 h with DMSO as a control. As depicted in Fig. 7a, the results are shown as the percent cell growth for each group compared to the control. There was no significant cell death even after 24 h of

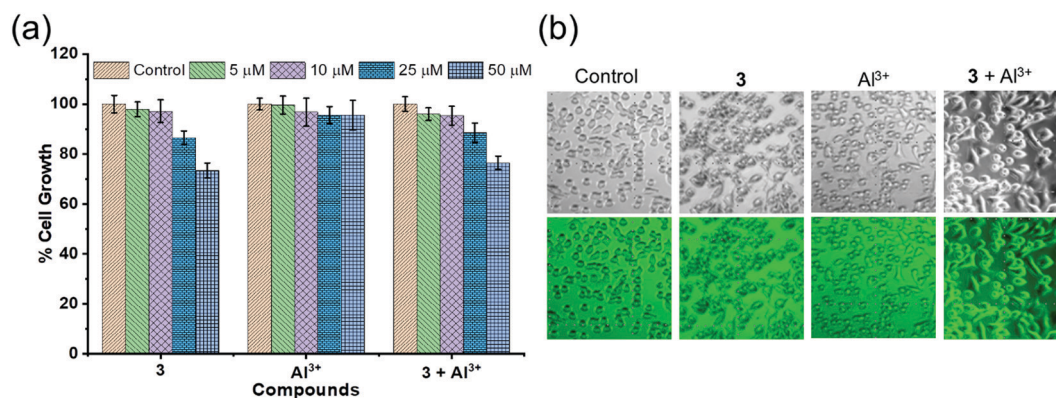

Fig. 7 (a) Cytotoxicity's of receptor **3**, Al<sup>3+</sup>, and receptor **3** + Al<sup>3+</sup> on the A549 cells after 24 h, (b) bright-field images (top row) and green channel (bottom row), control, receptor **3**, Al<sup>3+</sup>, and receptor **3** + Al<sup>3+</sup>.

treatment at 1–25  $\mu\text{M}$  of the receptor 3,  $\text{Al}^{3+}$  ions, and the receptor 3- $\text{Al}^{3+}$  complex. However, upon treatment at 50  $\mu\text{M}$  of receptor 3 and receptor 3- $\text{Al}^{3+}$  complex, about a 20% decrease in cell growth was observed. Hence, 10  $\mu\text{M}$  of receptor 3 was used for cell imaging applications. As shown in Fig. 7b, the cells did not show significant fluorescence upon incubation with  $\text{Al}^{3+}$  ions (10  $\mu\text{M}$ ) alone. However, very weak fluorescence was observed upon incubation of cells with receptor 3 (10  $\mu\text{M}$ ). Interestingly, the fluorescence intensity was increased upon incubation of cells with receptor 3 (10  $\mu\text{M}$ ) in the presence of  $\text{Al}^{3+}$  ions (10  $\mu\text{M}$ ). These results indicated that receptor 3 has a high potential in biological applications to detect  $\text{Al}^{3+}$  in an *in vitro* assay.

## 4. Conclusions

In conclusion, we have developed a new optical receptor 3 based on Schiff base chemistry that demonstrated excellent selectivity and sensitivity towards  $\text{Cu}^{2+}$  ions in UV-vis absorption spectroscopy. Whereas the developed receptor 3 showed excellent selectivity and sensitivity for the detection of  $\text{Al}^{3+}$  ion by using fluorescence spectroscopy. In either case, the receptor did not show any interference from other tested metal ions. The 2:1 binding stoichiometry of receptor 3 and  $\text{Al}^{3+}$  ions was confirmed by FT-IR, NMR, and mass spectroscopy. The reversibility of receptor 3 for  $\text{Al}^{3+}$  ions in the presence of EDTA ensures its ability as an excellent probe for detecting  $\text{Al}^{3+}$  in various samples, including living cells. Receptor 3 showed high selectivity for  $\text{Al}^{3+}$  with a  $K_a$  of  $4.8 \times 10^4 \text{ M}^{-1}$  and LOD of 3.0 nM. In comparison, the  $K_a$  for  $\text{Cu}^{2+}$  was  $1.3 \times 10^4 \text{ M}^{-1}$  and LOD of 1.9  $\mu\text{M}$ . Receptor 3 is an excellent chemosensor for detecting  $\text{Al}^{3+}$  ions indicated by its nanomolar range LOD. The quick response, easy synthesis, and high sensitivity make receptor 3 an ideal sensor for detecting  $\text{Cu}^{2+}$  and  $\text{Al}^{3+}$  ions. Further, the synthesized receptor showed a highly sensitive and highly specific fluorescent ‘turn-on’ effect ( $\lambda_{\text{em}} = 473 \text{ nm}$ ) for the 2:1 binding with  $\text{Al}^{3+}$  ions in a semi-aqueous medium and living cells.

## Author contributions

I. S. and P. T. contributed equally. Hence, both should be considered as the first authors. S. B. N. and A. K. designed the study; I. S., P. T., J. L., A. B., and S. D. W. performed the experiments; S. B. N., S. K. S., and A. K. analyzed and interpreted the data. S. K. S. completed the theoretical calculation. S. B. N. and A. K. supervised the research. S. B. N. and A. K. wrote the paper. All authors analyzed the data and commented on the paper.
