## Metal-templated synthesis of rigid and conformationally restricted cyclic bisporphyrins: specific retention times on a cyanopropyl-modified silica gel column†

Masaya Hashimoto,<sup>a</sup> Yusuke Kuramochi,<sup>a,b</sup> Sayumi Ito,<sup>b</sup> Yuho Kinbara<sup>a</sup> and Akiharu Satake<sup>a,b</sup>

A series of rigid and conformationally restricted cyclic bis(zinc porphyrin)s connected via 2,2'-bipyridine and phthalamide, isophthalamide, or terephthalamide moieties were prepared by metal-templated synthesis. The yields were significantly improved when compared with those obtained under metal-free conditions. In particular, phthalamide and terephthalamide derivatives were obtained only by metal-templated synthesis. Structural analyses and dynamics of the exchange between the conformers in each cyclic porphyrin were examined by NMR spectroscopy. Although the distances between the two zinc porphyrins were extended in the order of phthalamide, isophthalamide, and terephthalamide derivatives, the order of the specific retention of the cyclic porphyrins on cyanopropyl-modified silica gel (CN-MS) chromatography columns varied. Thus, this order was reversed in the isophthalamide and terephthalamide derivatives. Based on the rigid structure of the terephthalamide derivative, the origin of the specific retention on the CN-MS chromatography column was attributed to both the distance and rigidity of the cyclic porphyrins.

## Introduction

Cofacial bis(metalloporphyrin) derivatives are known as molecule-based functional materials. The functionalities are spread over various areas, such as chiral sensing,<sup>1,2</sup> molecular recognition,<sup>3</sup> supramolecular polymers,<sup>4</sup> oxygen activation,<sup>5,6</sup> and catalysts.<sup>6–8</sup> Because their functions are related to the distances and dihedral angles between the two porphyrins as well as conformational freedom, the preparation of various cofacial bis(metalloporphyrin)s has been beneficial.<sup>9–11</sup> Previously, we reported the synthesis of bis(zinc porphyrin)s connected through 2,2'-bipyridyl at 4,4'-positions. Their conformations were controlled to the cofacial orientation by complexation with metal ions on the 2,2'-bipyridyl moieties.<sup>12,13</sup>

Herein, we report the synthesis of a series of bis(zinc porphyrin)s connected through 2,2'-bipyridyl at 6,6'-positions, followed by covalent linkage of the opposite *meso*-positions of the

bis(zinc porphyrin)s. Thus, the two porphyrins are connected to different positions of a 2,2'-bipyridyl moiety by comparing them with the previous ones, and subsequently fixing them. These compounds are designed for different purposes from the previous one. The conceptual molecular structure of this project is shown in Fig. 1A. Here, a 2,2'-bipyridyl moiety is connected to the 6 and 6'-positions at the *meso*-position of two

† Electronic supplementary information (ESI) available: NMR spectra of 4Zn, 5Fb<sub>2</sub>, 6Fb<sub>2</sub>, 7Fb, 8Fb<sub>2</sub>, Zn<sub>2</sub>-CP<sub>2m</sub>, and Zn-CP<sub>2p</sub>. See DOI: 10.1039/d1ob00088h

metalloporphyrins, which are linked *via* an appropriate linker at the opposite *meso*-positions. The introduction of appropriate linkers regulates the distances and dihedral angles between the two metalloporphyrins, as well as their conformational freedom. In the linked bismetalloporphyrin, the association constants of metal ions on the 2,2'-bipyridyl moiety increase because the conformational freedom of the bipyridyl moiety is significantly decreased by the linkage. This is advantageous for assessing various metal ions with the 2,2'-bipyridyl moiety. In addition, an unusual orientation of metal complexes or organometallic complexes is expected on such a spatially restricted ligand.<sup>14</sup> In porphyrin moieties, various metal ions can also be introduced to systematically afford various functional multinuclear complexes. For instance, Mn, Fe, Co, Ru, and Rh porphyrins act as photoredox catalysts for olefin epoxidation,<sup>15,16</sup> CO<sub>2</sub> reduction,<sup>17–19</sup> oxidation of hydrocarbons,<sup>20,21</sup> water oxidation,<sup>22</sup> syntheses of *N*-acyl sulfimides and sulfoximines,<sup>23</sup> and carbon–carbon  $\sigma$ -bond oxidation.<sup>24</sup> Zinc porphyrin acts as a photosensitizer in photochemical reactions, for example, photoinduced  $\alpha$ -functionalization of aldehydes,<sup>25</sup> photoinduced living polymerization,<sup>26</sup> light-driven O<sub>2</sub> reduction,<sup>27</sup> and photocatalytic CO<sub>2</sub> reduction.<sup>28,29</sup> Thus, because the bismetalloporphyrin, as shown in Fig. 1A, has a coordination site by the 2,2'-bipyridyl part inside the restricted space, a systematic introduction of metal ions on the 2,2'-bipyridyl part will be beneficial for improving their catalytic activities or inducing successive catalytic reactions.

The particular molecular structures described in this paper are shown in Fig. 1B. We planned to synthesize a series of bis(zinc porphyrin) derivatives, **Zn<sub>2</sub>-CP2<sub>o</sub>**, **Zn<sub>2</sub>-CP2<sub>m</sub>**, and **Zn<sub>2</sub>-CP2<sub>p</sub>**, in which the two porphyrins are connected *via* phthalamide, isophthalamide, and terephthalamide, respectively. Among the bisporphyrin derivatives, the distances and dihedral angles between the two porphyrin moieties varied systematically. Previously, we reported the specific and efficient chromatographic isolation of cofacial cyclic trisporphyrins from

mixtures containing similar linear porphyrin derivatives on functionalized silica gel.<sup>32</sup> Indeed, this chromatography was useful for isolating cyclic bisporphyrin derivatives, even though they exist as minor products in crude mixtures. Another purpose of this work was to understand the principle of unique chromatographic behavior. The preparation of a series of similar bisporphyrins is useful for discussing the relationships between structures and retention behaviors on functionalized silica gels.

In this paper, we report the preparation of cofacial bisporphyrin derivatives **Zn<sub>2</sub>-CP2<sub>o</sub>**, **Zn<sub>2</sub>-CP2<sub>m</sub>**, and **Zn<sub>2</sub>-CP2<sub>p</sub>** by metal-templated macrocyclic formation followed by their efficient separation on cyanopropyl-modified silica gel (CN-MS). In the subsequent sections, the structural analyses and dynamics of the conformational changes of the bisporphyrin derivatives are described. Finally, a new insight into the origin of the specific retentions is discussed based on the relationships between retention behaviors and structural factors of a series of cyclic bisporphyrin derivatives.

## Results and discussion

Two synthetic routes were considered for the synthesis of **Zn<sub>2</sub>-CP2<sub>o,m,p</sub>**, as shown in Scheme 1. In the first route (**A**→**B**→**D**), nickel-mediated homocoupling is applied to produce **B**, followed by cross-linking with phthalic, isophthalic, or terephthalic dichloride to produce **Zn<sub>2</sub>-CP2<sub>o,m,p</sub>** (**D**), respectively. In the other route (**A**→**C**→**D**), the order of nickel-mediated homocoupling and cross-linking with acid dichloride is reversed.

Monoporphyrin **4Fb** was synthesized by the condensation of aldehydes **1** and **2** and dipyrromethane **3**, followed by oxidation with *p*-chloranil. After treatment with Zn(OAc)<sub>2</sub>, **4Zn** was isolated in 25% yield in two steps. The homocoupling reaction of **4Zn** was performed to result in the bisporphyrin **5Zn<sub>2</sub>**. Because the solubility of **5Zn<sub>2</sub>** was very low in various solvents, the purification of **5Zn<sub>2</sub>** was difficult at this stage.

Scheme 1 Two synthetic plans to construct cofacial cyclic bisporphyrins (**Zn<sub>2</sub>-CP2<sub>o,m,p</sub>**).

**Scheme 2** Synthesis of acyclic bisporphyrin **6Zn<sub>2</sub>**; bpy = 2,2'-bipyridine and cod = 1,5-cyclooctadiene.

Therefore, the zinc ions were removed in the presence of trifluoroacetic acid (TFA) to afford free-base bisporphyrin **5Fb<sub>2</sub>**, **5Fb<sub>2</sub>** was isolated by preparative gel permeation chromatography (GPC). The Boc-protecting groups in **5Fb<sub>2</sub>** were subsequently removed with neat TFA to afford **6Fb<sub>2</sub>**. Finally, zinc ions were re-introduced into the two porphyrin moieties of **6Fb<sub>2</sub>** to afford **6Zn<sub>2</sub>** in 69% yield in four steps (Scheme 2).

Macrocyclization of **6Zn<sub>2</sub>** with isophthaloyl dichloride was examined under various conditions to produce the diamide **Zn<sub>2</sub>-CP2<sub>m</sub>**. To a diluted diamine solution of **6Zn<sub>2</sub>** in dichloromethane (0.5 or 0.2 mM), 1.5 equivalents of isophthaloyl dichloride solution (0.9 mM) were slowly added with a syringe pump for 12 h in the presence of pyridine (4 equiv.) as a base. The reaction mixtures were analyzed by analytical high-performance liquid chromatography (HPLC) with a CN-MS column using a pyridine-based eluent, followed by matrix-assisted laser desorption ionization-time of flight (MALDI-TOF) mass spectrometry. An HPLC chart and a MALDI-TOF mass spectrum are shown in Fig. 2 and Fig. S9 and S10, respectively, in the ESI.†

In the HPLC chart, only the target macrocyclic compound **Zn<sub>2</sub>-CP2<sub>m</sub>** was retained on the column (retention time (RT) 2.9 min), and the linear compounds and the larger macrocyclic compound **Zn<sub>4</sub>-CP4<sub>m</sub>** were eluted in the initial RT region up to 1.5 min. In the MALDI-TOF mass spectrum, the relative intensities did not reflect their yields. In general, cyclic compounds such as **Zn<sub>2</sub>-CP2<sub>m</sub>** and **Zn<sub>4</sub>-CP4<sub>m</sub>** have a significant appearance as compared to linear porphyrin derivatives.

Therefore, the mass spectral data were used only for the characterization of the fractions by HPLC analysis. The HPLC-based yields of **Zn<sub>2</sub>-CP2<sub>m</sub>** were estimated to be 15 and 28%, respectively, for 0.5 and 0.2 mM solutions without metal-temple conditions. Although the dilution condition of 0.2 mM was better than that of 0.5 mM, further dilution of the system was not realistically applicable to scale up the system. Therefore, metal-templated synthesis was tested at a concentration of 0.2 mM in the presence of one equivalent of zinc, silver, and copper ions to improve the yield of the target macrocycle **Zn<sub>2</sub>-CP2<sub>m</sub>**. The yields of **Zn<sub>2</sub>-CP2<sub>m</sub>** determined from HPLC (Fig. S11 in the ESI†) are presented in Table 1. Addition of 1 equiv. of cationic  $\text{Zn}(\text{OTf})_2$  and  $\text{Ag}(\text{OTf})$  improved the yield to approximately 50%. When 1 equiv. of zinc chloride, zinc acetate, and excess amounts of  $\text{Zn}(\text{OTf})_2$  were used, the yields decreased compared with those in the absence of metal ions.  $\text{Cu}(\text{OTf})_2$  was ineffective in yielding **Zn<sub>2</sub>-CP2<sub>m</sub>**. In the cases of  $\text{Cu}(\text{OTf})_2$  and 5 equiv. of  $\text{Zn}(\text{OTf})_2$ ,

**Fig. 2** HPLC chart of a crude mixture after reaction of **6Zn<sub>2</sub>** (0.5 mM) with isophthaloyl dichloride. Column: Cosmosil 5CN-MS (7.5 mm I.D. × 5 cm). Eluent: toluene/pyridine (15/85). Flow rate: 1.0 mL min<sup>-1</sup>. Monitored at 563 nm. Cyclic diamide **Zn<sub>2</sub>-CP2<sub>m</sub>** was eluted at a RT of 2.9 min (HPLC yield: 15%). The most other components were eluted up to a RT of 1.5 min without retention.

**Fig. 3** (a) UV-vis spectral change of  $5Zn_2$  ( $7.5 \times 10^{-6}$  M) during titration with  $Ag(OTf)$  in  $CHCl_3$ . (Inset) The relationship between the change of absorbance at 450 nm and equivalents of added  $Ag(OTf)$ . A curve fitting analysis is shown as a dotted line. (b) Normalized overlaid UV-vis spectra (in  $CHCl_3$ ) of  $4Zn$  (black),  $5Zn_2$  (red),  $5Zn_2$  with 1 equiv. of  $Zn(OTf)_2$  (cyan),  $5Zn_2$  with 1 equiv. of  $Ag(OTf)$  (green) between 400 and 450 nm. The whole spectra (350–650 nm) are presented in Fig. S14† as (A)–(D).

some precipitates (probably insoluble complexes composed of metal ions and porphyrin derivatives) were produced, which were separated before the HPLC analysis. One of the reasons for the low yields was the formation of precipitates.

To obtain insight into the effects of metal ions on macrocyclization, UV-vis titration experiments for  $5Zn_2$  ( $7.5 \times 10^{-6}$  M) with  $Ag(OTf)$ ,  $Zn(OTf)_2$ , and  $Cu(OTf)_2$  were conducted in  $CHCl_3$  (Fig. 3a, and Fig. S12 and S13†). In the case of  $Ag(OTf)$  and  $Zn(OTf)_2$ , complexation of  $5Zn_2$  with metal ions converged to 1 : 1 even in the presence of 1 equiv. of metal ions under diluted conditions (the insets of Fig. 3a and S12†), whereas further complexation or transformation occurred after the formation of a 1 : 1 complex in the presence of  $Cu(OTf)_2$  (inset of Fig. S13†). These results suggest that one equivalent of  $Ag(OTf)$  and  $Zn(OTf)_2$  is sufficient and appropriate to form 1 : 1 complexes.

The UV-vis spectra of  $4Zn$  and  $5Zn_2$  in the absence and presence of 1 equiv. of  $Zn(OTf)_2$  or  $Ag(OTf)$  recorded in  $CHCl_3$  are shown in Fig. S14.† The spectral shapes and peak maxima of the Soret bands varied slightly. To compare the Soret bands,

the overlaid spectra are shown in Fig. 3b. In bis(porphyrin) systems, the exciton coupling model<sup>10,30,31</sup> is useful for qualitatively discussing the relative orientation between the two porphyrins. As compared to the UV-vis spectrum of zinc porphyrin monomer  $4Zn$  (427 nm), in which there is no exciton coupling, metal-free bipyridine  $5Zn_2$  gave split Soret bands at 420 and 430 nm, whose peaks were both blue and red-shifted. On the one hand, the red-shifted band is ascribed to the head-to-tail type of excitonic coupling between the two transition dipoles of X in the *anti*-conformation of  $5Zn_2$ , as shown in Fig. 4. On the other hand, the blue-shifted band is because of excitonic couplings of the parallel orientation between the two transition dipoles of Y and the oblique orientation of X in the *syn* conformation (Fig. 4). Therefore, the metal-free bipyridine  $5Zn_2$  adopts both *anti*- and *syn*-conformations by freely rotating along the C–C bond in the bipyridyl moiety. In the presence of 1 equiv. of  $Zn(OTf)_2$ , the red-shifted Soret band significantly decreased, whereas the blue-shifted band increased. These results indicate that the *syn* conformation was predominantly formed by the coordination of zinc ions on the bipyridyl

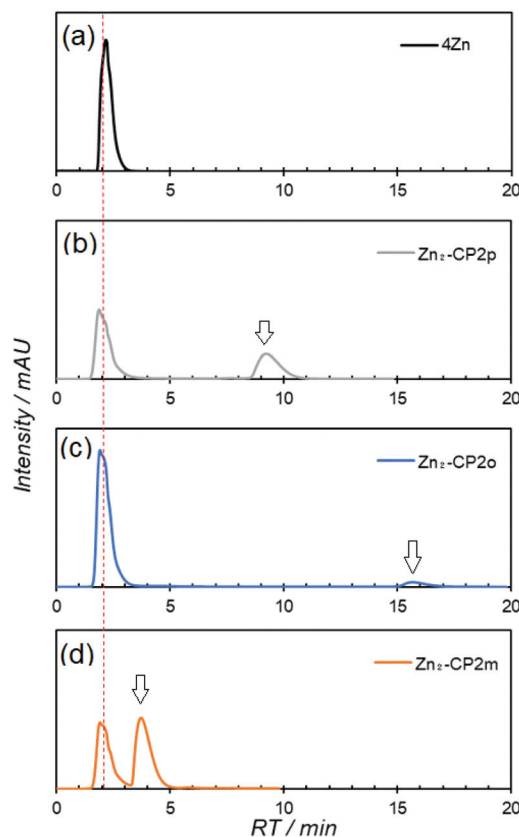

**Fig. 4** Interaction of transition dipole moments of the bisporphyrin.

part to fix the rotation along the C–C bond. In the case of Ag(OTf), since the red-shifted band decreased, the decrease in the *anti*-conformation was confirmed by the coordination of silver ions on the bipyridyl. However, the blue-shifted Soret band was not remarkable. This result probably because of the differences in ion radii of Zn(II) (0.60 Å) and Ag(I) (0.67 Å). Exciton coupling is highly sensitive to the relative distance between the transition dipoles. Both 1 equiv. of Zn(OTf)<sub>2</sub> and Ag(OTf) acted as preferable metal templates to fix the *syn* conformation of **5Zn<sub>2</sub>**. Notably, real macrocyclization was performed in **6Zn<sub>2</sub>**, in which two amino groups exist on the terminal parts. Therefore, selective interactions between Zn(OTf)<sub>2</sub> (or Ag(OTf)) and the 2,2'-bipyridyl moiety in **6Zn<sub>2</sub>** are required, because the cationic metal ions may also interact with the terminal amino groups. If more than 1 equiv. of the metal template is added, the undesired interactions with the amino groups result in precipitates, and the reactivity of the amines interacting with acyl chlorides may decrease. Therefore, excess amounts of Zn(OTf)<sub>2</sub> and Ag(OTf) should not be added to the metal-templated macrocyclization system.

Another route (A→C→D in Scheme 1) to obtain **Zn<sub>2</sub>-CP2<sub>m</sub>** was also examined, as shown in Scheme 3. Removal of Boc groups on **4Zn** was performed by treatment with TFA to obtain **7Fb**. Condensation of **7Fb** (2 equiv.) with isophthaloyl dichloride in dichloromethane gave bisamide **8Fb<sub>2</sub>**, which was reacted with zinc acetate to afford **8Zn<sub>2</sub>** in 38% yield in three steps. As a key step, nickel-mediated macrocyclization was applied to **8Zn<sub>2</sub>** under several conditions. However, the target macrocyclic compound, **Zn<sub>2</sub>-CP2<sub>m</sub>**, was obtained in a low yield (3% from HPLC in Fig. S15†). Therefore, the first synthetic route, A→B→D, shown in Scheme 1, was developed.

To obtain **Zn<sub>2</sub>-CP2<sub>m</sub>**, metal-templated synthesis of **6Zn<sub>2</sub>** with isophthaloyl dichloride in the presence of 1 equiv. of Zn(OTf)<sub>2</sub> or Ag(OTf) was the most appropriate. Therefore, the same conditions were applied to obtain **Zn<sub>2</sub>-CP2<sub>p</sub>** and **Zn<sub>2</sub>-CP2<sub>o</sub>** using terephthaloyl and phthaloyl dichlorides, instead of isophthaloyl dichloride. The yields of **Zn<sub>2</sub>-CP2<sub>p</sub>** and **Zn<sub>2</sub>-CP2<sub>o</sub>** were determined by HPLC using a CN-MS column. The chromatograms of the crude reaction mixtures are shown in Fig. 5, and the reaction yields are summarized in Table 2. On the CN-MS column using pyridine as the eluent, only the target cyclic compounds were significantly retained. The RTs were 9.2 and 15.6 min for **Zn<sub>2</sub>-CP2<sub>p</sub>** and **Zn<sub>2</sub>-CP2<sub>o</sub>**, respectively, with a flow rate of 0.5 mL min<sup>-1</sup>. The RTs of **Zn<sub>2</sub>-CP2<sub>p</sub>** and **Zn<sub>2</sub>-**

**Fig. 5** HPLC charts of (a) **4Zn<sub>2</sub>**, crude mixtures after the reaction of **6Zn<sub>2</sub>** (0.5 mM) in the presence of 1 equiv. of Zn(OTf)<sub>2</sub> with (b) terephthaloyl dichloride, (c) phthaloyl dichloride, and (d) isophthaloyl dichloride. Column: Cosmosil 5CN-MS (7.5 mm I.D. × 5 cm), eluent: pyridine 100%, flow rate: 0.5 mL min<sup>-1</sup>, monitored at 563 nm. Arrows indicate the peaks corresponding to (b) **Zn<sub>2</sub>-CP2<sub>p</sub>**, (c) **Zn<sub>2</sub>-CP2<sub>o</sub>**, and (d) **Zn<sub>2</sub>-CP2<sub>m</sub>**, respectively.

**CP2<sub>o</sub>** were significantly longer than those of **Zn<sub>2</sub>-CP2<sub>m</sub>** (4.0 min) recorded under the same conditions (Fig. 5d). It is noted that all other compounds, except for the cyclic dimers, were eluted at RT 2 min without retention.

In both cases using terephthaloyl and phthaloyl dichlorides, no macrocyclic compounds were obtained in the absence of Zn(OTf)<sub>2</sub> or Ag(OTf), whereas macrocyclic compounds, **Zn<sub>2</sub>-CP2<sub>p</sub>** and **Zn<sub>2</sub>-CP2<sub>o</sub>**, were observed in the mixtures prepared under metal-templated conditions. The yield of **Zn<sub>2</sub>-CP2<sub>p</sub>** was

**Scheme 3** Alternative synthetic route to cyclic bisporphyrin **Zn<sub>2</sub>-CP2<sub>m</sub>**.

**Table 2** Yields of  $\text{Zn}_2\text{-CP2}_p$  and  $\text{Zn}_2\text{-CP2}_o$  in the cyclization reaction

Entry	Linker (1.5 eq.)	Metal (1.0 eq.)	$\text{Zn}_2\text{-CP2}_p$ or $\text{Zn}_2\text{-CP2}_o$ HPLC yield (%)
1	Terephthaloyl dichloride ( <i>p</i> )	—	0
2	Terephthaloyl dichloride ( <i>p</i> )	$\text{Zn}(\text{OTf})_2$	19
3	Terephthaloyl dichloride ( <i>p</i> )	$\text{Ag}(\text{OTf})$	24
4	Phthaloyl dichloride ( <i>o</i> )	—	0
5	Phthaloyl dichloride ( <i>o</i> )	$\text{Zn}(\text{OTf})_2$	5
6	Phthaloyl dichloride ( <i>o</i> )	$\text{Ag}(\text{OTf})$	3

approximately 20%, whereas that of  $\text{Zn}_2\text{-CP2}_o$  was less by several percent. The reason for the low yields of  $\text{Zn}_2\text{-CP2}_o$  is that phthalimide derivatives, such as **9** in Fig. S16,† were formed significantly, which were detected by MALDI-TOF mass spectrometry (Fig. S17†). While the yield of  $\text{Zn}_2\text{-CP2}_o$  was very low, it was never obtained in the absence of a metal template. Therefore, the metal-template method is especially effective for the preparation of the kinetically disadvantageous phthalimide  $\text{Zn}_2\text{-CP2}_o$ , compared with phthalimide derivatives, such as **9**, which are immediately formed from an amine part and phthaloyl dichloride. The yield of  $\text{Zn}_2\text{-CP2}_p$  was slightly increased using  $\text{Ag}(\text{OTf})$  instead of  $\text{Zn}(\text{OTf})_2$ , suggesting that the larger  $\text{Ag}(\text{i})$  ion is beneficial for obtaining bis(porphyrin)  $\text{Zn}_2\text{-CP2}_p$ , in which the two amide parts are located more apart than those in  $\text{Zn}_2\text{-CP2}_m$ .

### Efficient isolation

After the metal-templated macrocyclization,  $\text{Zn}_2\text{-CP2}_m$ ,  $\text{Zn}_2\text{-CP2}_o$ , and  $\text{Zn}_2\text{-CP2}_p$  were obtained as mixtures, including

other linear oligomers. Although the yields of  $\text{Zn}_2\text{-CP2}_m$ ,  $\text{Zn}_2\text{-CP2}_o$  and  $\text{Zn}_2\text{-CP2}_p$  were moderate or significantly low compared with other byproducts, isolation of the cyclic compounds was accomplished efficiently using a preparative CN-MS column using pyridine as an eluent. Under these conditions, all the compounds, except for the cyclic compounds, were eluted first without any retention, and then, almost only the cyclic compounds were eluted independently. As a result, tens of milligrams of pure  $\text{Zn}_2\text{-CP2}_m$  and  $\text{Zn}_2\text{-CP2}_p$  were isolated, and a few milligrams of  $\text{Zn}_2\text{-CP2}_o$  were obtained. It is noted that HPLC yields determined from the crude mixtures and the corresponding isolated yields were almost the same, indicating that the decrease in the isolated yields during the purification process was suppressed.

### Structural analyses of macrocycles on $^1\text{H}$ NMR

To estimate the conformational structures of the macrocyclic porphyrins  $\text{Zn}_2\text{-CP2}_o$ ,  $\text{Zn}_2\text{-CP2}_m$ , and  $\text{Zn}_2\text{-CP2}_p$ , their  $^1\text{H}$  NMR spectra in pyridine- $d_5$  are compared in Fig. 6. In pyridine- $d_5$ , two pyridine molecules coordinate to the two zinc parts to form five-coordinated complexes. Because the exchange rate of the coordinating pyridine molecules to peripheral non-coordinating pyridine is high at room temperature (*ca.* 23–25 °C), it is difficult to detect the coordinating pyridine in NMR spectroscopy.

Consequently, the labile coordination behavior of pyridine eliminates the anisotropy of coordination. Therefore, only the conformational changes in the macrocyclic frames can be considered in the NMR spectra. The  $^1\text{H}$  NMR spectra of  $\text{Zn}_2\text{-CP2}_o$  (Fig. 6a) and  $\text{Zn}_2\text{-CP2}_m$  (Fig. 6b) show a pseudo  $C_{2v}$  symmetric

**Fig. 6**  $^1\text{H}$  NMR (500 MHz) spectra of (a)  $\text{Zn}_2\text{-CP2}_o$ , (b)  $\text{Zn}_2\text{-CP2}_m$ , and (c)  $\text{Zn}_2\text{-CP2}_p$  in pyridine- $d_5$  (12–7 ppm). Asterisks indicate the signals of pyridines. Open circles in (c) indicate the signals of the minor isomer.

structure at room temperature, respectively, indicating that the two porphyrin planes are cofacial on average. In contrast, two conformational isomers were observed for  $\text{Zn}_2\text{-CP2}_p$  (Fig. 6c). The major isomer is a pseudo  $C_{2v}$  symmetric structure, whereas the minor isomer (indicated by open circles in Fig. 6c) is not symmetric. The chemical shifts of amide-NH groups in  $\text{Zn}_2\text{-CP2}_o$ ,  $\text{Zn}_2\text{-CP2}_m$ , and  $\text{Zn}_2\text{-CP2}_p$  (for the major isomer) are observed at 11.58, 11.17, and 10.48 ppm, respectively. These differences occur when the two cofacial porphyrins are close to each other, and as a result, the amide protons are affected by the ring current produced by the nearby porphyrin moieties. In particular, the amide protons of  $\text{Zn}_2\text{-CP2}_o$  are deshielded by existing just outside the ring currents. In the case of the amide protons in  $\text{Zn}_2\text{-CP2}_m$  and  $\text{Zn}_2\text{-CP2}_p$ , the degree of deshielding effects was smaller. Therefore, the order of the lower chemical shifts of the NH groups in  $\text{Zn}_2\text{-CP2}_o$ ,  $\text{Zn}_2\text{-CP2}_m$ , and  $\text{Zn}_2\text{-CP2}_p$  (for the major isomer) suggests that the average distances of the two porphyrins in the cofacial porphyrins increase in the same order ( $\text{Zn}_2\text{-CP2}_o < \text{Zn}_2\text{-CP2}_m < \text{Zn}_2\text{-CP2}_p$ ).

The assignments of all the  $^1\text{H}$  and  $^{13}\text{C}$  NMR (Fig. S19<sup>†</sup>) signals of  $\text{Zn}_2\text{-CP2}_m$  were obtained using various two-dimensional NMR techniques, namely HH-correlation spectroscopy (HH-COSY) (15 mM) (Fig. S20<sup>†</sup>), heteronuclear single quantum correlation (HSQC) (15 mM) (Fig. S21<sup>†</sup>), heteronuclear multiple bond coherence (HMBC) (15 mM) (Fig. S22<sup>†</sup>), and nuclear Overhauser effect spectroscopy (NOESY) (6 mM) (Fig. S23<sup>†</sup>). The assignments and observed NOE correlations are shown in Fig. S24<sup>†</sup>. The chemical shifts of aromatic parts, Ar-15, Ar(m)-18, 19, and 20 varied slightly in the different NMR samples (15 and 6 mM) prepared from the same  $\text{Zn}_2\text{-CP2}_m$  material. The chemical shifts are presented in Table S1 in the ESI.<sup>†</sup> These results suggest that the proton signals of the aromatic parts are significantly affected by the circumstances and concentrations.

Because stronger NOE correlation signals were observed between NH-17 and Ar-16, and NH-17 and Ar(m)-20, the major conformer was determined as *syn-1* in Fig. 7, in which the amide groups exist on the near side of Ar-16 and Ar(m)-20. Meanwhile, relatively weaker correlation signals were also observed between NH-17 and Ar-15 and between NH-17 and Ar(m)-18. These NOE correlations indicate the existence of *syn-2* and *anti* isomers as minor components. Distinct conformers could not be observed at room temperature. Rapid intercon-

Fig. 7 Exchange among conformers, *syn1* (major), *anti*, and *syn2* of  $\text{Zn}_2\text{-CP2}_m$ .

conversion (conformational changes) between *syn-1*, *anti*, and *syn-2* was observed at room temperature.

In the case of  $\text{Zn}_2\text{-CP2}_p$ , two conformational isomers were clearly separated in the  $^1\text{H}$  NMR spectra of pyridine- $d_5$  at a ratio of 85:15 (Fig. 6c and Fig. S25 and S26<sup>†</sup>). The signal pattern of the major conformer is simple, indicating a symmetric structure, whereas the pattern of the minor isomer is complicated (Fig. S26<sup>†</sup>). For assignments of the  $^1\text{H}$  and  $^{13}\text{C}$  NMR (Fig. S27<sup>†</sup>) signals of the major isomer of  $\text{Zn}_2\text{-CP2}_p$ , various two-dimensional NMR techniques, namely HH-COSY (Fig. S28<sup>†</sup>), HSQC (Fig. S29<sup>†</sup>), and NOESY (Fig. S30, S31, and S32<sup>†</sup>), were performed. The assignments and observed NOE correlations in the major conformer are shown in Fig. S33.<sup>†</sup> As the intense NOE correlation between 10.44 and 7.33 was observed in the major conformer (Fig. S30<sup>†</sup>), the NH groups in the amide moieties are directed to the porphyrin groups, as illustrated in Fig. 8 (*syn*).

Parts of correlation signals between the major and minor conformers were observed in the NOESY (Fig. S30, S31, and S32<sup>†</sup>). The correlations were because of the chemical exchange between the two conformational isomers. The correlated signals among the amide groups, the  $\beta$ -protons, and the methyl groups on the mesityl moieties are summarized in Table S2.<sup>†</sup> Other minor signals could not be assigned because of overlapping with the major signals. In the minor conformer, the two NH groups are separately observed at 11.67 and 11.30 ppm. The inner methyl group in mesityl moieties in the major conformer at 1.47 ppm was correlated with four methyl groups in the minor conformer at 2.56, 1.98, 0.61, and -1.04 ppm. They are widely distributed. Two of the four methyl groups in the minor conformer are upper-field shifted (0.61 and -1.04 ppm), whereas the other two methyl groups in the minor conformer are lower-field shifted (2.56 and 1.98 ppm). These results indicate that the two porphyrin moieties are twisted in the minor conformer, and the former two methyl groups are shielded to a significant extent by the oppo-

Fig. 8 Schematics of two conformers of  $\text{Zn}_2\text{-CP2}_p$ . (left) Major symmetric *syn* form and (right) minor unsymmetric *anti* form.

site facial porphyrin, whereas the latter two are shielded to a lesser extent. A schematic of the two conformational isomers is shown in Fig. 8 (*anti*). In the major symmetric form (*syn*), the NH groups were directed to the inside of the ring. In the minor non-symmetric form (*anti*), the two porphyrin groups are twisted, resulting in four methyl groups that are not identical. In the case of  $\text{Zn}_2\text{-CP2}_p$ , the exchange rate between the two conformational isomers was slower than that in  $\text{Zn}_2\text{-CP2}_m$ . The observations are used in the discussion in the last section.

### Structural analyses of macrocycles on UV-vis spectra

In contrast to the NMR spectra, UV-vis spectra reflect the populations of conformational isomers, because the timescale of the measurements is considerably faster than the exchange rate among the conformational isomers. The UV-vis spectra in pyridine are shown in Fig. 9E to compare the Soret bands (410–450 nm) for monomer  $4\text{Zn}$ , and  $\text{Zn}_2\text{-CP2}_{o,m,p}$ . The highest absorption peak in each spectrum was normalized in the spectra. All three cyclic dimers ( $\text{Zn}_2\text{-CP2}_{o,m,p}$ ) have blue-shifted Soret bands compared with the monomer  $4\text{Zn}$ , indicating that the two zinc porphyrins in  $\text{Zn}_2\text{-CP2}_{o,m,p}$  face each other, as shown in Fig. 10. The excitonic couplings between the two parallel transition dipole components of Y and the oblique transition dipole component X contribute to the blue shift. The degrees of the blue shifts and full width at half

maximum (FWHM) are different among the three compounds, suggesting that the orientation and distance between the two porphyrins in each cyclic dimer are different. In the three blue-shifted spectra, the spectrum of  $\text{Zn}_2\text{-CP2}_m$  was blue-shifted to the highest extent, and the FWHM was narrow. These features indicate that the relative positions of the two porphyrins in  $\text{Zn}_2\text{-CP2}_m$  are constant and parallel. Although the existence of *syn-2* and *anti* forms of  $\text{Zn}_2\text{-CP2}_m$  was suggested by the  $^1\text{H}$  NMR spectrum (Fig. 7), the population of the minor *anti* isomer was small. In the case of  $\text{Zn}_2\text{-CP2}_p$ , the absorption in the Soret band region was broadened. This is ascribed to the overlapping of the UV-vis spectra of conformers, *syn* and *anti*, on the amide groups (Fig. 8), as observed in the  $^1\text{H}$  NMR spectrum (Fig. 6). The degree of the blue shift of  $\text{Zn}_2\text{-CP2}_o$  was lowest in the three cyclic porphyrins, although the distance between the two porphyrin groups was expected to be the closest among the three conformers. The UV-vis spectrum of  $\text{Zn}_2\text{-CP2}_o$  indicates that the two porphyrins adopt a twisted conformation, in which the transition dipoles of Y adopt an oblique orientation.<sup>30</sup> In Fig. 11, the possible conformers of  $\text{Zn}_2\text{-CP2}_o$  are presented. The *anti*-conformers are expected to be twisted. Since the  $^1\text{H}$  NMR spectrum of  $\text{Zn}_2\text{-CP2}_o$  showed a relatively simple pattern corresponding to a pseudo-symmetric structure (Fig. 6a), the exchange between the two *anti* conformers must occur in the NMR timescale.

Fig. 9 UV-vis spectra in pyridine of (A)  $4\text{Zn}$ , (B)  $\text{Zn}_2\text{-CP2}_m$ , (C)  $\text{Zn}_2\text{-CP2}_o$ , and (D)  $\text{Zn}_2\text{-CP2}_p$ , (E) Overlaid spectra of (A)–(D) in the Soret band region.

### Calculated models of $\text{Zn}_2\text{-CP2}_o$ , $\text{Zn}_2\text{-CP2}_m$ , and $\text{Zn}_2\text{-CP2}_p$

In Fig. 12, S35, and S36,<sup>†</sup> the energy-minimized molecular models of conformers of  $\text{Zn}_2\text{-CP2}_o$ ,  $\text{Zn}_2\text{-CP2}_m$ , and  $\text{Zn}_2\text{-CP2}_p$  obtained by density-functional theory (DFT) calculations (B3LYP/6-31G(d)) are shown. In the case of  $\text{Zn}_2\text{-CP2}_o$ , *anti* form is more stable than the *syn* form by  $4.3 \text{ kcal mol}^{-1}$  ( $18.0 \text{ kJ mol}^{-1}$ ) in a vacuum.

Fig. 11 Schematics of exchange among conformers of  $\text{Zn}_2\text{-CP2}_o$ . (left and right) *anti* forms and (center) *syn* form.

Fig. 12 Molecular structures of *syn*- and *anti*-conformers of  $\text{Zn}_2\text{-CP2}_o$ , optimized with DFT calculations (B3LYP/6-31G(d) *in vacuo*), and the energy difference.

Intramolecular hydrogen bonding is observed in the *anti* form, and the two porphyrin moieties are twisted (Fig. 12), as discussed in the previous section.

Two *syn* forms are compared in  $\text{Zn}_2\text{-CP2}_m$  (Fig. S35<sup>†</sup>), and *syn-1* is more stable by 6.3 kcal mol<sup>-1</sup> (26.4 kJ mol<sup>-1</sup>) in a vacuum. This result is consistent with the NOESY spectrum of  $\text{Zn}_2\text{-CP2}_m$ , in which a stronger correlation signal was observed between Ar-16 and NH-17, and Ar-20 and NH-17 (Fig. S23<sup>†</sup>).

In the case of  $\text{Zn}_2\text{-CP2}_p$ , *syn* and *anti* forms are compared in Fig. S36,<sup>†</sup> and *syn* form is more stable by 5.8 kcal mol<sup>-1</sup> (24.3 kJ mol<sup>-1</sup>) in a vacuum. In pyridine-d<sub>5</sub> at 298 K, the ratio of *syn* to *anti* is 85 : 15, corresponding to  $\Delta G^\circ = 4.3$  kJ mol<sup>-1</sup>. The difference in the  $\Delta G^\circ$  values ( $\Delta\Delta G^\circ$  20.0 kJ mol<sup>-1</sup>) corresponds to the solvation energy of pyridine. It is noted that the signals of *syn* and *anti* conformers in the <sup>1</sup>H NMR spectrum of  $\text{Zn}_2\text{-CP2}_p$  are ascribed to the difference in the activation energy between the *syn*- and *anti*-conformers of  $\text{Zn}_2\text{-CP2}_p$  from those of  $\text{Zn}_2\text{-CP2}_m$ . The former must be larger than that of  $\text{Zn}_2\text{-CP2}_m$ .

The distances between the two zinc ions in  $\text{Zn}_2\text{-CP2}_o$  (*anti* form),  $\text{Zn}_2\text{-CP2}_m$  (*syn* form) and  $\text{Zn}_2\text{-CP2}_p$  (*syn* form) are estimated to be 7.87, 8.30 Å, and 9.27 Å, respectively.<sup>‡</sup> The order of the distances between the two porphyrins is consistent with the order of the lower chemical shifts of the NH groups in  $\text{Zn}_2\text{-CP2}_o$ ,  $\text{Zn}_2\text{-CP2}_m$ , and  $\text{Zn}_2\text{-CP2}_p$  (for the major isomer) (Fig. 13). The NH protons are located at the edges of the porphyrin moieties. Thus, they are sensitive to the ring current of the nearby porphyrins. In the molecular model of  $\text{Zn}_2\text{-CP2}_o$ , the contribution of the deshielding effect to the NH groups seems large.

### Consideration of retention times on the CN-MS column

Specific retention phenomena were observed for  $\text{Zn}_2\text{-CP2}_o$ ,  $\text{Zn}_2\text{-CP2}_m$ , and  $\text{Zn}_2\text{-CP2}_p$  by CN-MS chromatography. Our

<sup>‡</sup>The B3LYP/6-31G(d) level of theory was used and the contributions from dispersion interactions were not considered for the calculations. Please refer to Fig. S37 in the ESI,<sup>†</sup> which presents models constructed using the B3LYP-D3/6-31G(d) level of theory (*in vacuo*). Contributions from dispersion interactions were considered for the calculations

Fig. 13 Molecular structures and the distances between two zinc ions of (a) *anti* form of  $\text{Zn}_2\text{-CP2}_o$ , (b) *syn-1* form of  $\text{Zn}_2\text{-CP2}_m$ , and (c) *syn* form of  $\text{Zn}_2\text{-CP2}_p$ , optimized with DFT calculations (B3LYP/6-31G(d) *in vacuo*). The calculated distances between two zinc ions are presented.

group previously observed the specific retention of cyclic zinc porphyrin trimers<sup>32</sup> and cyclic nickel porphyrin dimers.<sup>14</sup> Therefore, this report is the third example of a specific retention phenomenon. For specific retention, the structural requirements become obvious. Thus, the compounds are cyclic and have two porphyrin moieties connected *via* bipyridine. However, these two structural requirements are not sufficient conditions. At present, the mechanism of specific retention remains unclear. To discuss this mechanism, we believe that the collection of more examples of relationships between structures and retention behaviors is necessary. In this report, we have prepared three new cyclic bisporphyrins,  $\text{Zn}_2\text{-CP2}_o$ ,  $\text{Zn}_2\text{-CP2}_m$ , and  $\text{Zn}_2\text{-CP2}_p$ . Retention behavior is now discussed.

As shown in Fig. 5, the retention times were extended in the following order:  $\text{Zn}_2\text{-CP2}_m$ ,  $\text{Zn}_2\text{-CP2}_p$ , and  $\text{Zn}_2\text{-CP2}_o$ . Unexpectedly, the order does not follow the distances between the two zinc porphyrins in  $\text{Zn}_2\text{-CP2}_o$ ,  $\text{Zn}_2\text{-CP2}_m$ , and  $\text{Zn}_2\text{-CP2}_p$ . From the comparison of cyclic zinc porphyrin trimers<sup>32</sup> and cyclic nickel porphyrin dimers,<sup>14</sup> we expected that a shorter distance between the two zinc porphyrins would be advantageous for longer retention. However, the order of  $\text{Zn}_2\text{-CP2}_m$  and  $\text{Zn}_2\text{-CP2}_p$  was inverted, and the retention time of  $\text{Zn}_2\text{-CP2}_p$  was significantly longer. This result cannot be explained by differences in the static structures prepared by molecular models (Fig. 13). In the <sup>1</sup>H NMR analyses, conformational isomers (*syn* and *anti*) were present in both  $\text{Zn}_2\text{-CP2}_m$  and  $\text{Zn}_2\text{-CP2}_p$ . The exchange rate between the *syn* and *anti* isomers was slower for  $\text{Zn}_2\text{-CP2}_p$ . The slower exchange rate was ascribed to the restriction of conformational freedom in  $\text{Zn}_2\text{-CP2}_p$ . Here, we assume that cyanopropyl moieties on the modified silica gel interact with the major *syn* forms of both  $\text{Zn}_2\text{-CP2}_m$  and  $\text{Zn}_2\text{-CP2}_p$ , and the retention is determined by the period of the interaction. The period of the interaction depends on the rigidity of the cyclic porphyrins. Thus,  $\text{Zn}_2\text{-CP2}_p$  is advantageous for longer retention than  $\text{Zn}_2\text{-CP2}_m$ . In the case of  $\text{Zn}_2\text{-CP2}_o$ , the close distance between the two porphyrin moieties probably contributes to the significantly longer retention observed in Fig. 5.

This new insight into the mechanism of the unique chromatographic behavior of the CN-MS column was proposed by preparing a series of cyclic porphyrin dimers,  $\text{Zn}_2\text{-CP2}_o$ ,  $\text{Zn}_2\text{-}$

CP2<sub>m</sub>, and Zn<sub>2</sub>-CP2<sub>p</sub>. The discussion that the retention depends on the rigidity of the cyclic porphyrins requires further studies.

## Conclusions

Metal-templated bisamide linking of bis(zinc porphyrin) with two aniline groups connected through 2,2'-bipyridyl at 6,6'-positions with phthaloyl dichloride, isophthaloyl dichloride, and terephthaloyl dichloride was accomplished to afford Zn<sub>2</sub>-CP2<sub>o</sub>, Zn<sub>2</sub>-CP2<sub>m</sub>, and Zn<sub>2</sub>-CP2<sub>p</sub>. The yields were significantly improved compared to those obtained under metal-free conditions. In particular, phthalimide and terephthalamide derivatives were obtained only by metal-templated synthesis.

Although the target macrocyclic compounds Zn<sub>2</sub>-CP2<sub>o</sub>, Zn<sub>2</sub>-CP2<sub>m</sub>, and Zn<sub>2</sub>-CP2<sub>p</sub> were obtained as mixtures containing significant amounts of linear derivatives, the target compounds were isolated using a preparative CN-MS column using pyridine as an eluent, without any loss during the purification process. This interesting result is because of the specific retention of the cyclic porphyrin compounds on the CN-MS column.

Structural analyses of Zn<sub>2</sub>-CP2<sub>o</sub>, Zn<sub>2</sub>-CP2<sub>m</sub>, and Zn<sub>2</sub>-CP2<sub>p</sub> were performed by NMR and UV-vis spectroscopies as well as DFT calculations. In the UV-vis method, populations of conformational isomers and the relative distances and orientations between the two zinc porphyrins in each cyclic porphyrin dimer could be estimated. It was seen that the two porphyrin moieties were twisted in Zn<sub>2</sub>-CP2<sub>o</sub>, whereas they were parallel in Zn<sub>2</sub>-CP2<sub>m</sub>. The distances between the two zinc porphyrins were extended in the following order: Zn<sub>2</sub>-CP2<sub>o</sub>, Zn<sub>2</sub>-CP2<sub>m</sub>, and Zn<sub>2</sub>-CP2<sub>p</sub>. This was confirmed by <sup>1</sup>H NMR and DFT calculations.

In the NMR methods, exchanges between the conformers in each cyclic porphyrin were observed. The relative exchange rate was slow in Zn<sub>2</sub>-CP2<sub>p</sub>, as compared with that of Zn<sub>2</sub>-CP2<sub>m</sub>. As a result, *syn* and *anti* conformers were observed separately in the <sup>1</sup>H NMR spectrum of Zn<sub>2</sub>-CP2<sub>p</sub>.

The order of specific retention of the cyclic porphyrins on a CN-MS chromatography column was not followed by the distances between the two zinc porphyrins in Zn<sub>2</sub>-CP2<sub>o</sub>, Zn<sub>2</sub>-CP2<sub>m</sub>, and Zn<sub>2</sub>-CP2<sub>p</sub>. Based on the rigid structure of the terephthalamide derivative, Zn<sub>2</sub>-CP2<sub>p</sub>, the origin of the specific retention on a CN-MS chromatography column was attributed to both the distance and rigidity of the cyclic porphyrins.

## Experimental

### General procedure

All chemicals and solvents were of commercial reagent quality and were used without further purification unless otherwise stated. Aldehyde **1**, (3-formyl-phenyl)-carbamic acid *tert*-butyl ester, was prepared according to the literature.<sup>33</sup> *N,N*-Dimethylformamide (DMF) was dried over molecular sieves of

size 4 Å and distilled under reduced pressure. The reactions were performed on silica gel 60F<sub>254</sub> TLC plates (Merck). The silica gel utilized for column chromatography was purchased from Kanto Chemical Co. Inc.: Silica gel (Spherical, Neutral) 40–100 μm and (Flash) 40–50 μm. Cyanopropyl-modified silica gel (CN-MS, Cyanogel) (dp: 40 μm, pore size: 60 Å) was purchased from Yamazen, and a mixture of toluene and pyridine (85/15 v/v) and 100% pyridine were used as eluents. <sup>1</sup>H and <sup>13</sup>C NMR, distortionless enhancement by polarization transfer 135 (DEPT 135), COSY, HSQC, and NOESY spectra were recorded using a JEOL JNM-ECS-500. Chemical shifts were recorded in parts per million (ppm) relative to tetramethylsilane. MALDI-TOF mass spectra were recorded on a JEOL JMS S-3000 system with dithranol as a matrix with sodium iodide (NaI). UV-vis absorption spectra were collected using a square cell (path length = 1.0 cm) on a JASCO V-650 spectrometer. Steady-state emission spectra were collected on a Hitachi F-4500 spectrometer and corrected for the response of the detector system. The fluorescence intensities were normalized at the absorbance of the excitation wavelength.

### High-performance liquid chromatographies (HPLCs)

HPLCs were carried out by using the following three systems: [System 1] JASCO PU-2080plus and MD-2018plus systems equipped with two TSK G2500H<sub>HR</sub> (Tosoh, 7.8 mm × 30 cm, exclusion limit: 20 000 Da) and one TSK G2000H<sub>HR</sub> (Tosoh, 7.8 mm × 30 cm, exclusion limit: 10 000 Da) columns using pyridine as an eluent. [System 2] JASCO PU-2089 and MD-44010 systems equipped with a Cosmosil 5CN-MS column (nacalai tesque, 7.5 mm I.D. × 5 cm) using toluene/pyridine (15/85) or 100% pyridine as an eluent. [System 3: Preparative HPLC] LC-908 (JAI) attached to one TSK G2500H<sub>HR</sub> column and one G2000H<sub>HR</sub> column eluted with pyridine as an eluent.

### Computational methods

DFT calculations were carried out using the Gaussian 09 package of programs.<sup>34</sup> Each structure was fully optimized using the B3LYP functional with the 6-31G(d) basis set. The stationary points were verified using vibrational analysis.

### Synthesis of 4Zn

A 500 mL three-necked round-bottom flask was charged with aldehyde **1** (0.312 g, 1.42 mmol), 6-bromo-2-pyridinecarboxaldehyde **2** (0.266 g, 1.42 mmol), dipyrromethane **3** (0.751 g, 2.84 mmol), and Ar-saturated CHCl<sub>3</sub> (285 mL). Then, 1 mL of CHCl<sub>3</sub> solution containing BF<sub>3</sub>·OEt<sub>2</sub> (100 μL, 0.796 mmol) was slowly added to it, and the mixture was stirred at rt under an Ar atmosphere in the dark. After 0.5 h, 1 mL of CHCl<sub>3</sub> solution containing Et<sub>3</sub>N (200 μL, 1.59 mmol) and *p*-chloranil (1.05 g, 4.26 mmol) were added to it, and the mixture was stirred at room temperature for 19 h. The solvent was evaporated to dryness. The black-purple residue was purified twice with flush silica gel columns (eluent: CHCl<sub>3</sub>), giving a purple solid containing a symmetric byproduct porphyrin and **4Fb** (0.616 g). The solid was placed in a 100 mL flask and dissolved in CHCl<sub>3</sub> (20 mL). A small amount (~1 mL) of methanol con-

taining Zn(OAc)<sub>2</sub> (0.632 g, 3.44 mmol) was added to it, and the mixture was stirred for 42 h. The resulting solution was washed with water (×2) and brine. The organic layer was dried over anhydrous Na<sub>2</sub>SO<sub>4</sub> and the solvent was evaporated to dryness. The crude purple solid (0.625 g) was purified with a flush silica gel column (eluent: toluene:ethyl acetate = 70:1→30:1→10:1), giving pure target porphyrin **4Zn** (0.286 g, 0.299 mmol) with 21% yield (based on aldehyde **1**). <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>) δ/ppm = 8.87 (d, *J* = 4.4 Hz, 2H), 8.82 (d, *J* = 4.4 Hz, 2H), 8.80 (d, *J* = 4.4 Hz, 2H), 8.75 (d, *J* = 4.4 Hz, 2H), 8.25 (d, *J* = 6.8 Hz, 1H), 7.94–7.86 (m, 4H), 7.60 (s, 1H), 7.28 (s, 4H), 2.63 (s, 6H), 1.81 (s, 12H), 1.45 (s, 9H); <sup>13</sup>C NMR (75 MHz, CDCl<sub>3</sub>) δ/ppm = 162.70, 150.35, 149.99, 149.87, 149.60, 143.48, 140.71, 139.36, 139.04, 137.97, 137.58, 136.81, 132.66, 131.61, 131.51, 130.86, 129.64, 129.13, 128.79, 128.32, 127.75, 127.11, 126.76, 125.39, 119.69, 117.74, 116.24, 80.91, 29.81, 28.25, 21.57. MALDI-TOF MS of **4Zn** *m/z* 854.2242 (M)<sup>+</sup>, calcd for C<sub>54</sub>H<sub>47</sub>BrN<sub>6</sub>O<sub>2</sub>Zn 854.2232.

### Synthesis of **5Zn**<sub>2</sub>

A 200 mL Schlenk tube was charged with **4Zn** (108 mg, 0.112 mmol), 2,2'-bipyridine (22.0 mg, 0.141 mmol). After the Schlenk tube was evacuated and filled with Ar gas, dry DMF degassed with freeze-thaw cycles (100 mL) and 1,5-cyclooctadiene (42 μL, 0.342 mmol) were added to the tube. After the mixture was stirred for 10 min at room temperature, Ni(cod)<sub>2</sub> (960 mg, 3.49 mmol) was added. The reaction mixture was sonicated and stirred at rt in the dark. After overnight stirring, the resulting mixture was added to a small amount of CHCl<sub>3</sub> (~20 mL) in a perfluoroalkoxy alkane (PFA)-coated flask. The Schlenk tube was washed with CHCl<sub>3</sub> (~20 mL). The combined CHCl<sub>3</sub> solution was washed with 0.3 M citric acid solution (×4), 25% ammonium solution (×3), and dried over anhydrous Na<sub>2</sub>SO<sub>4</sub>. The solution was passed through a membrane filter (Omnipore, 0.1 μm) to remove the precipitates. The filtrate was concentrated to dryness, giving a crude purple solid containing **5Zn**<sub>2</sub> (110 mg). Retention times of HPLC (columns: TOSOH G2500H<sub>HR</sub> × 2 + G2000H<sub>HR</sub> × 1, eluent: pyridine, flow rate: 1.0 mL min<sup>-1</sup>): 21.62 min for **5Zn**<sub>2</sub> and 23.68 min for monomers containing **4Zn**. UV-vis absorption of a pure sample obtained by Zn insertion to a pure **5Fb**<sub>2</sub>: λ<sub>max</sub> (CHCl<sub>3</sub>)/nm = 430 (ε = 6.7 × 10<sup>5</sup> M<sup>-1</sup> cm<sup>-1</sup>) and 553 (ε = 3.4 × 10<sup>4</sup> M<sup>-1</sup> cm<sup>-1</sup>). NMR spectroscopic analysis could not be performed due to its poor solubility in any solvent. MALDI-TOF MS of **5Zn**<sub>2</sub> (C<sub>108</sub>H<sub>94</sub>N<sub>12</sub>O<sub>4</sub>Zn<sub>2</sub>, exact MS 1750.61) gave only fragment signals corresponding to de-Boc derivatives: *m/z* 1551.49 (**5Zn**<sub>2</sub> – (Boc)<sub>2</sub> + (H)<sub>3</sub>)<sup>+</sup>, calcd for C<sub>98</sub>H<sub>78</sub>N<sub>12</sub>Zn<sub>2</sub> 1551.51.

### Synthesis of **5Fb**<sub>2</sub>

A 20 mL flask was charged with a crude purple solid containing **5Zn**<sub>2</sub> (110 mg) and CHCl<sub>3</sub> (20 mL). Trifluoroacetic acid (TFA) (0.1 mL, 1.31 mmol) was slowly added to it and the mixture was stirred at rt for 1.5 h. The resulting solution was slowly poured into a saturated NaHCO<sub>3</sub> aqueous solution (50 mL) in an ice-bath. The organic layer was transferred into a PFA-coated funnel and the aqueous layer was extracted with

CHCl<sub>3</sub> (10 mL × 3). The combined organic layer was washed with water and dried over anhydrous Na<sub>2</sub>SO<sub>4</sub>. The solution was passed through a membrane filter (Omnipore, 0.1 μm) to remove the precipitates, and the filtrate was concentrated to dryness. The resulting residue was purified with a preparative HPLC using pyridine as an eluent, giving a purple solid, **5Fb**<sub>2</sub> (57.8 mg, 35.5 μmol) in 69% yield (2 steps from **4Zn**). <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>) δ/ppm = 9.02–9.00 (m, 6H), 8.86 (d, *J* = 4.0 Hz, 4H), 8.79 (d, *J* = 4.0 Hz, 4H), 8.72 (d, *J* = 4.0 Hz, 4H), 8.26 (d, *J* = 4.0 Hz, 2H), 8.11 (t, *J* = 6.8 Hz, 4H), 7.96 (s, 4H), 7.67 (t, *J* = 6.8 Hz, 2H), 7.30 (s, 8H), 6.76 (s, 2H), 2.64 (s, 12H), 1.88 (s, 24H), 1.53 (s, 18H), –2.53 (s, 4H); <sup>13</sup>C NMR (75 MHz, CDCl<sub>3</sub>) δ/ppm = 160.19, 155.37, 153.13, 142.87, 139.55, 138.57, 137.89, 137.00, 135.90, 130.63, 129.74, 127.92, 127.44, 124.86, 123.89, 120.46, 119.48, 118.62, 118.03, 117.74, 80.86, 28.52, 21.82, 21.62. MALDI-TOF MS of **5Fb**<sub>2</sub> (C<sub>108</sub>H<sub>98</sub>N<sub>12</sub>O<sub>4</sub>; C<sub>108</sub>H<sub>94</sub>N<sub>12</sub>O<sub>4</sub>Zn<sub>2</sub>, exact MS 1626.78) gave only fragment signals corresponding to [**5Fb**<sub>2</sub> – (Boc) – (*t*-butoxy) + (H)<sub>2</sub>]<sup>+</sup> (*m/z* 1454.70) and [**5Fb**<sub>2</sub> – (Boc)<sub>2</sub> + (H)<sub>2</sub>]<sup>+</sup> (*m/z* 1426.68).

### Synthesis of **6Fb**<sub>2</sub>

TFA (2.0 mL) was slowly added to **5Fb**<sub>2</sub> (26.5 mg, 16.3 μmol) in a 25 mL flask, and the mixture was stirred for 1 h. The resulting solution was slowly poured into a saturated NaHCO<sub>3</sub> aqueous solution (50 mL) in an ice-bath. The organic layer was transferred to a PFA-coated funnel and the aqueous layer was extracted with CHCl<sub>3</sub> (10 mL × 3). The combined organic layer was washed with water and dried over anhydrous Na<sub>2</sub>SO<sub>4</sub>. The solvent was evaporated to dryness, giving a purple solid **6Fb**<sub>2</sub> (22.0 mg). TLC (toluene:EtOAc = 30:1) *R*<sub>f</sub> = 0.50; <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>) δ/ppm = 8.99–9.03 (m, 6H), 8.93 (d, *J* = 4.4 Hz, 4H), 8.79 (d, *J* = 4.4 Hz, 4H), 8.72 (d, *J* = 4.4 Hz, 4H), 8.25 (d, *J* = 7.8 Hz, 2H), 8.12 (t, *J* = 7.8 Hz, 2H), 7.75–7.40 (m (br), 6H), 7.31 (s, 8H), 7.10 (d, *J* = 7.8 Hz, 2H), 2.65 (s, 12H), 1.89 (s, 24H), –2.53 (s, 4H); UV-vis absorption: λ<sub>max</sub> (CHCl<sub>3</sub>)/nm = 425, 516, 551, 589; fluorescence (λ<sub>ex</sub> = 515 nm, CHCl<sub>3</sub>): λ<sub>max</sub>/nm = 648, 713. MALDI-TOF MS of **6Fb**<sub>2</sub> (C<sub>98</sub>H<sub>82</sub>N<sub>12</sub>; M.W. 1427.8): found *m/z* 1428.0 (M)<sup>+</sup>.

### Synthesis of **6Zn**<sub>2</sub>

A 20 mL flask was charged with **6Fb**<sub>2</sub> (22.0 mg) and CHCl<sub>3</sub> (5 mL). Zn(OAc)<sub>2</sub> (56.8 mg, 310 μmol) in a small amount of methanol (~1 mL) was added to it and the mixture was stirred at rt for 19 h. The resulting solution was transferred to a PFA-coated funnel and washed with water (×2) and brine. The organic layer was passed through Phase Separator paper (Whatman). The solvent was evaporated to dryness, giving a purple solid **6Zn**<sub>2</sub> (28.3 mg, 18.2 μmol) quantitatively from **5Fb**<sub>2</sub>. TLC (toluene:EtOAc = 30:1) *R*<sub>f</sub> = 0.13; UV-vis absorption: λ<sub>max</sub> (CHCl<sub>3</sub>)/nm = 423, 559, 600; fluorescence (λ<sub>ex</sub> = 515 nm, CHCl<sub>3</sub>) λ<sub>max</sub>/nm = 607, 651. NMR spectroscopic analysis could not be performed due to the poor solubility in any solvent. MALDI-TOF MS of **6Zn**<sub>2</sub> *m/z* 1551.50 (M + H)<sup>+</sup>, calcd for C<sub>98</sub>H<sub>79</sub>N<sub>12</sub>Zn<sub>2</sub> 1551.51.

### Synthesis of Zn<sub>2</sub>-CP2<sub>o,m,p</sub> (metal templated synthesis)

A 10 mL flask was charged with **6Zn**<sub>2</sub> (5.0 mg, 3.2 μmol) and dry CH<sub>2</sub>Cl<sub>2</sub> (5 mL). A CH<sub>3</sub>CN (~1 mL) solution containing the metal ion (3.2 μmol) was slowly added to it, and the resulting solution was transferred to a 300 mL three-necked round bottom flask and diluted with dry CH<sub>2</sub>Cl<sub>2</sub> to be 0.2 mM of **6Zn**<sub>2</sub>. A dry CH<sub>2</sub>Cl<sub>2</sub> solution (5 mL) containing dichloride (4.8 μmol) and pyridine (1 μL, 12 μmol) was slowly added to the **6Zn**<sub>2</sub> solution for 12 h with a microsyringe pump (KD Scientific, KDS 100). The solution was poured into a saturated NaHCO<sub>3</sub> aqueous solution (50 mL) in a PFA-coated flask. The organic layer was washed with water (×3), and passed through Phase Separator paper (Whatman). The solvent was evaporated to dryness, giving a purple solid. The solids obtained by the reactions with three kinds of dichlorides were analyzed with HPLCs to estimate the reaction yields.

### Purification of Zn<sub>2</sub>-CP2<sub>o,m,p</sub>

The crude mixtures containing the target cyclic dimers were purified on cyanopropyl modified silica gel columns (YFLC Gel, CN, Yamazene Co. pore size: 40 μm) with a mixed solvent of toluene and pyridine (15/85 v/v) and 100% pyridine as an eluent. The solvent was evaporated to dryness, giving pure target products.

**Zn<sub>2</sub>-CP2<sub>o</sub>** <sup>1</sup>H NMR (500 MHz, pyridine-*d*<sub>5</sub>) δ/ppm = 11.59 (s, 2H), 9.05 (s, 2H), 8.73 (s, 4H), 8.64 (s, 4H), 8.45–8.42 (8H), 8.28 (t, *J* = 8.0 Hz, 2H), 8.06–7.91 (m, 4H), 7.72 (t, *J* = 7.8 Hz, 2H), 7.36 (s, 8H), 7.11 (s, 4H), 2.53 (s, 12H), 1.79 (s, 12H), 1.50 (s, 12H); MALDI-TOF-MS (dithranol) *m/z* 1680.4970 (M)<sup>+</sup>, calcd for [C<sub>106</sub>H<sub>81</sub>N<sub>12</sub>O<sub>2</sub>Zn<sub>2</sub>]<sup>+</sup> 1680.5110.

**Zn<sub>2</sub>-CP2<sub>m</sub>** <sup>1</sup>H and <sup>13</sup>C NMR assignments are shown in Fig. S23.† MALDI-TOF-MS (dithranol) *m/z* 1681.5197 (M + H)<sup>+</sup>, calcd for [C<sub>106</sub>H<sub>81</sub>N<sub>12</sub>O<sub>2</sub>Zn<sub>2</sub>]<sup>+</sup> 1681.5183.

**Zn<sub>2</sub>-CP2<sub>p</sub>** <sup>1</sup>H and <sup>13</sup>C NMR assignments are shown in Fig. S31.† MALDI-TOF-MS (dithranol) *m/z* 1703.4968 (M + Na)<sup>+</sup>, calcd for [C<sub>106</sub>H<sub>80</sub>N<sub>12</sub>O<sub>2</sub>Zn<sub>2</sub>Na]<sup>+</sup> 1703.5003.

### Synthesis of 7Fb

TFA (4.0 mL) was slowly added to **4Zn** (50.4 mg, 52.7 μmol) in a 25 mL flask, and the mixture was stirred at rt for 1 h. The resulting solution was poured into a saturated NaHCO<sub>3</sub> aqueous solution (50 mL) in an ice-bath. The organic layer was transferred to a PFA-coated funnel and the aqueous layer was extracted with CHCl<sub>3</sub> (10 mL × 3). The combined organic layer was washed with water and dried over anhydrous Na<sub>2</sub>SO<sub>4</sub>. The solvent was evaporated to dryness, giving a purple solid **7Fb** (37.7 mg, 47.5 μmol) in 91% yield. <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>) δ/ppm = 8.89 (d, *J* = 4.8 Hz, 2H), 8.78 (d, *J* = 4.8 Hz, 2H), 8.72 (d, *J* = 4.8 Hz, 2H), 8.67 (d, *J* = 4.8 Hz, 2H), 8.25 (dd, *J* = 6.4, 2.0 Hz, 1H), 7.91–7.86 (m, 2H), 7.61 (d, *J* = 7.8 Hz, 2H), 7.54 (s, 1H), 7.47 (t, *J* = 7.8 Hz, 1H), 7.27 (s, 4H), 7.05 (m, 1H), 3.92 (s (br), 2H), 2.62 (s, 6H), 1.82 (s, 12H), –2.65 (s, 2H). MALDI-TOF MS of **7Fb** *m/z* 792.24 (M)<sup>+</sup>, calcd for C<sub>49</sub>H<sub>41</sub>BrN<sub>6</sub> 792.26.

### Synthesis of 8Fb<sub>2</sub>

A 50 mL two-necked flask was charged with **7Fb** (17.1 mg, 21.5 μmol), 4-dimethyl-aminopyridine (DMAP, 2.8 mg, 22.9 μmol) and dry pyridine (2 mL). A dry CH<sub>2</sub>Cl<sub>2</sub> solution (4 mL) containing isophthaloyl chloride (3.2 mg, 15.8 μmol) was slowly added to the **7Fb** solution with a microsyringe pump (kd Scientific, KDS 100). After 15.5 h, the solution was poured into a saturated NaHCO<sub>3</sub> aqueous solution in a PFA-coated flask. The organic layer was washed with water (×3), and passed through Phase Separator paper (Whatman). The solvent was evaporated to dryness, giving a purple solid (16.6 mg). The crude solid was purified with a flush silica gel column (eluent: CHCl<sub>3</sub>), affording a pure target compound **8Fb<sub>2</sub>** (7.8 mg, 4.5 μmol) in 42% yield. TLC (CHCl<sub>3</sub>:MeOH = 50:1) *R<sub>f</sub>* = 0.63; <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>) δ/ppm = 8.81 (d, *J* = 4.8 Hz, 4H), 8.78 (d, *J* = 4.8 Hz, 4H), 8.71 (d, *J* = 4.8 Hz, 4H), 8.66 (d, *J* = 4.8 Hz, 4H), 8.49 (s, 1H), 8.34 (s, 2H), 8.21 (s, 1H), 8.15 (dd, *J* = 8.0, 1.2 Hz, 2H), 8.01–7.87 (m, 8H), 7.71–7.67 (m, 2H), 7.51–7.41 (m, 2H), 7.25 (s, 4H), 7.21 (s, 4H), 2.59 (s, 12H), 1.81 (s, 12H), 1.76 (s, 12H), –2.68 (s, 4H); MALDI-TOF-MS (dithranol) *m/z* 1715.5282 (M + H)<sup>+</sup>, calcd for [C<sub>106</sub>H<sub>85</sub>Br<sub>2</sub>N<sub>12</sub>O<sub>2</sub>]<sup>+</sup> 1715.5285; UVvis absorption: λ<sub>max</sub> (CHCl<sub>3</sub>)/nm = 420, 517.

### Synthesis of 8Zn<sub>2</sub>

A 10 mL flask was charged with **8Fb<sub>2</sub>** (7.8 mg, 4.5 μmol) and CHCl<sub>3</sub> (3 mL). Zn(OAc)<sub>2</sub> (8.2 mg, 45 μmol) in a small amount of methanol was added to it and the mixture was stirred at room temperature for 5 h. The resulting solution was transferred to a PFA-coated funnel and washed with water (×3). The organic layer was passed through Phase Separator paper (Whatman). The solvent was evaporated to dryness, giving a purple solid **8Zn<sub>2</sub>** (8.0 mg, 4.3 μmol) in 96% yield. TLC (CHCl<sub>3</sub>:MeOH = 50:1) *R<sub>f</sub>* = 0.13; UV-vis absorption: λ<sub>max</sub> (CHCl<sub>3</sub>)/nm = 426, 554. MALDI-TOF MS of **8Zn<sub>2</sub>** *m/z* 1838.34 (M)<sup>+</sup>, calcd for C<sub>106</sub>H<sub>80</sub>Br<sub>2</sub>N<sub>12</sub>O<sub>2</sub>Zn<sub>2</sub> 1838.35.

### Synthesis of Zn<sub>2</sub>-CP2<sub>m</sub> (coupling)

A 20 mL Schlenk tube was charged with **8Zn<sub>2</sub>** (3.0 mg, 1.6 μmol) and 2,2'-bipyridine (0.3 mg, 1.9 μmol). After the Schlenk tube was evacuated and filled with Ar gas, dry DMF degassed with freeze–thaw cycles (10 mL) and 1,5-cyclooctadiene (0.6 μL, 1.9 μmol) were added to the tube. After the mixture was stirred for 10 min at rt, Ni(cod)<sub>2</sub> (32.7 mg, 119 μmol) was added. The reaction mixture was sonicated and stirred at 50 °C in the dark. After overnight stirring, the resulting mixture was added to a small amount of CHCl<sub>3</sub> in a perfluoroalkoxy alkane (PFA)-coated flask. The Schlenk tube was washed with CHCl<sub>3</sub>. The combined CHCl<sub>3</sub> solution was washed with 0.3 M citric acid solution (×4) and 25% ammonium solution (×3), and dried over anhydrous Na<sub>2</sub>SO<sub>4</sub>. The solution was passed through a membrane filter (Omnipore, 0.1 μm) to remove the precipitates. The filtrate was concentrated to dryness, giving a purple solid (3.5 mg). The solid was analyzed by HPLC to estimate the reaction yield.
