# Effect of axial molecules and linker length on CO<sub>2</sub> adsorption and selectivity of CAU-8: a combined DFT and GCMC simulation study†

 Diem Thi-Xuan Dang,<sup>ID</sup>\*<sup>ab</sup> Hieu Trung Hoang,<sup>ab</sup> Tan Le Hoang Doan,<sup>ID</sup><sup>ab</sup> Nam Thoai,<sup>bc</sup> Yoshiyuki Kawazoe<sup>def</sup> and Duc Nguyen-Manh<sup>ID</sup><sup>g</sup>

Density Functional Theory (DFT) and Grand Canonical Monte Carlo (GCMC) calculations are performed to study the structures and carbon dioxide (CO<sub>2</sub>) adsorption properties of the newly designed metal–organic framework based on the CAU-8 (CAU stands for Christian-Albrechts Universität) prototype. In the new MOFs, the 4,4'-benzophenonedicarboxylic acid (H<sub>2</sub>BPDC) linker of CAU-8 is substituted by 4,4'-oxalylbis(azanediy)l) dibenzoic acid (H<sub>2</sub>ODA) and 4,4'-teraphthaloylbis(azanediy)l) dibenzoic acid (H<sub>2</sub>TDA) containing amide groups (–CO–NH– motif). Furthermore, MgO<sub>6</sub> octahedral chains where dimethyl sulfoxide (DMSO) decorating the axial position bridged two Mg<sup>2+</sup> ions are considered. The formation energies indicate that modified CAU-8 is thermodynamically stable. The reaction mechanisms between the metal clusters and the linkers to form the materials are also proposed. GCMC calculations show that CO<sub>2</sub> adsorptions and selectivities of Al-based MOFs are better than those of Mg-based MOFs, which is due to DMSO. Amide groups made CO<sub>2</sub> molecules more intensively distributed besides organic linkers. CO<sub>2</sub> uptakes and selectivities of MOFs containing H<sub>2</sub>TDA linkers are better in comparison with those of MOFs containing H<sub>2</sub>BPDC linkers or H<sub>2</sub>ODA linkers.

## 1. Introduction

Metal–organic frameworks (MOFs) are synthesized by self-assembly of metal clusters and organic linkers.<sup>1</sup> MOFs are a new class of microporous and mesoporous materials that have attracted much attention for various applications, such as gas storage and separations, catalysis, proton transfer, and drug delivery.<sup>2–11</sup> They can be easily self-assembled from simple metal salts and organic linkers. The richness of both inorganic and organic components for the construction of MOFs has provided us tremendous opportunities to synthesize a large number of MOF materials whose pore sizes, pore surface functions, and pore volumes can be systematically tailored to the above-mentioned specific applications.

Carbon dioxide (CO<sub>2</sub>) storage in MOFs is under intensive research and is used industrially to prepare many intermediate or fine chemicals. Additionally, the selective capture of CO<sub>2</sub> from flue gas and natural gas has become the most urgent issue due to climate change concerns.<sup>12</sup> Among the reported MOFs for CO<sub>2</sub> adsorption and selectivity applications, MOF-74 and MIL-53 are the most well-known, for both materials, the 3D structures are formed from chains running parallel to each other, which results in their potentials for resistance to interpenetration and isoreticular expansion.<sup>13–15</sup> MOF-74 is constructed from infinite chains [M<sup>II</sup><sub>3</sub>O<sub>3</sub>(CO<sub>2</sub>)<sub>3</sub>]<sub>∞</sub> whereas M is metal with II valence such as Mg, Zn, Fe, ... and 2,5-dioxido-1,4-benzenedicarboxylic acid (H<sub>4</sub>DOBDC).<sup>16</sup> MOF-74 is characteristic of the highest density of open metal sites on the 1D channel pore surfaces with a diameter of about 11 Å. The high CO<sub>2</sub> adsorption ability of MOF-74 is due to the strong Lewis acid and base interactions between metal ions and oxygen atom of CO<sub>2</sub>, as well as carbon atom of CO<sub>2</sub> with oxygen atoms in organic linkers.<sup>17</sup> Among MOF-74, MOF-74(Mg) has a surface area of 1495 m<sup>2</sup> g<sup>−1</sup> and exceptional CO<sub>2</sub> uptake with one of the highest known ambient temperature (25 °C) capacities (~5 mmol g<sup>−1</sup> at 0.1 bar to ~8 mmol g<sup>−1</sup> at 1 bar CO<sub>2</sub>).<sup>18</sup> The remarkable CO<sub>2</sub> storage of MOF-74(Mg) may be due to the increased ionic character of the Mg–O bond.<sup>18</sup> The post-synthetic functionalization of MOF-74(Mg) with tetraethylene-pentamine (TEPA) resulted in a CO<sub>2</sub> adsorption performance as high as 26.9 wt% *versus* 23.4 wt% for the original MOF due to

the extra binding sites provided by the multiunit amines.<sup>19</sup> Analogous expansion series to MOF-74(Mg) have been synthesized such as MOF-184(Mg) (pore diameter of 20 Å, surface area of 4050 m<sup>2</sup> g<sup>-1</sup>), [Mg<sub>2</sub>(olsalazine)] (pore diameter of 23.3 Å, surface area of 2331 m<sup>2</sup> g<sup>-1</sup>), ... however, CO<sub>2</sub> uptake in MOF-184(Mg) and [Mg<sub>2</sub>(olsalazine)] are 3.04 mmol g<sup>-1</sup> and 5 mmol g<sup>-1</sup> at 25 °C and 1 bar, respectively, lower than those in the original MOF due to the decrease in the number of metal centers on a unit cell.<sup>20,21</sup> MIL-53 consists of infinity chains [M<sup>III</sup><sub>2</sub>(OH)<sub>2</sub>(CO<sub>2</sub>)<sub>4</sub>]<sub>∞</sub> whereas M is metal with III valence such as Al, Cr, Fe, ... and benzene-1,4-dicarboxylate terephthalate acid (H<sub>2</sub>BDC).<sup>22</sup> These materials have structural flexibility, also known as “breathing behavior” that leads to a transition between a narrow-pore and a large-pore structure – whose unit cell volume can change up to 40%.<sup>23</sup> MIL-53 is capable of adsorption of nearly 40 wt% for CO<sub>2</sub>.<sup>24</sup> MIL-53 has been used for separating CO<sub>2</sub> from methane (CH<sub>4</sub>) thanks to the strong interaction between CO<sub>2</sub> molecules with the hydrogen of the corner-sharing hydroxyl groups in the MIL-53.<sup>25</sup> Among MIL-53, MIL-53(Al) is extremely stable at high temperatures (up to 773 K), which is an uncommon property compared with its analogues.<sup>26</sup> Because of breathing behavior, replacing the BDC linker with longer linkers produced non-porous materials such as MIL-69 or PCN-72.<sup>27,28</sup>

Recently, Reinsch *et al.* synthesized CAU-8(Al) (CAU stands for Christian-Albrechts Universität) formulated as [Al(OH)(BPDC)] (BPDC: 4,4'-benzophenone dicarboxylate) whose structure is established by [Al<sub>2</sub>(OH)<sub>2</sub>(CO<sub>2</sub>)<sub>4</sub>]<sub>∞</sub> chains connected by V-shape BPDC ligands as shown in Fig. 1a.<sup>29</sup> CAU-8(Al) adopts the similar infinity chains with MIL-53(Al), but these chains running perpendicular to each other. Since there are no studies on CO<sub>2</sub> storage and selectivity capacity on CAU-8(Al); this stimulates us to choose it as the object for this paper. Recently, several MOFs have been constructed with amide (-CO-NH-) decorated ligands, showing high CO<sub>2</sub> adsorption capacities due to these functional groups.<sup>30,31</sup> We, therefore, consider a strategy to enhance the CO<sub>2</sub> storage and selectivity of CAU-8(Al) by optimizing the organic linker by anchoring this polar functional group. We select two organic linkers: 4,4'-(oxalylbis(azanediyl)dibenzoic acid (H<sub>2</sub>ODA) and 4,4'-(terephthaloylbis(azanediyl)dibenzoic acid (H<sub>2</sub>TDA) (Fig. 1c). We consider these linkers with two groups of -CO-NH- but different lengths to study the effect of linker length on the surface area as well as the ability to absorb and select CO<sub>2</sub> of the material. In addition, the linker in the CAU-8 has a V-shape whereas numerous porous MOFs are constructed from linear organic linkers in previously reported literature,<sup>9,32</sup> we have used linear linkers in this study. The 1a and 1b structures are formed from CAU-8(Al) by replacing the H<sub>2</sub>BPDC linker with H<sub>2</sub>ODA and H<sub>2</sub>TDA linkers, respectively.

In 2013, Zhou *et al.* synthesized PCN-72 which is comprised of {Mg<sub>2</sub>[OS(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub>(CO<sub>2</sub>)<sub>4</sub>]<sub>∞</sub> cluster and TTTP ligand (2',3',5',6'-tetramethyl-[1,1':4',1''-terphenyl]4,4''-dicarboxylate) and whose topology is similar to MIL-53.<sup>28</sup> The structure of {Mg<sub>2</sub>[OS(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub>(CO<sub>2</sub>)<sub>4</sub>]<sub>∞</sub> cluster is similar to [Al<sub>2</sub>(OH)<sub>2</sub>(CO<sub>2</sub>)<sub>4</sub>]<sub>∞</sub> but axial position bridged two metal ions -OH is replaced by dimethyl sulfoxide OS(CH<sub>3</sub>)<sub>2</sub> (DMSO) (Fig. 1b). PCN-72 is a non-

Fig. 1 (a) CAU-8(Al) structure. (b) [Al<sub>2</sub>(OH)<sub>2</sub>(CO<sub>2</sub>)<sub>4</sub>]<sub>∞</sub> cluster and {Mg<sub>2</sub>[OS(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub>(CO<sub>2</sub>)<sub>4</sub>]<sub>∞</sub> cluster, (c) 4,4'-(4-carboxybenzamidido)benzoic acid (H<sub>2</sub>ODA) and 4,4'-(terephthaloylbis(azanediyl)dibenzoic acid (H<sub>2</sub>TDA) linkers. (d) 2b structure. Atom color: Al, blue; Mg, orange; C, brown; N, pale blue; O, red; H, pale pink; S, yellow.

porous material because of its topology and long linear ligand. After removing coordinated DMSO at 360 °C, PCN-72 can selectively adsorb CO<sub>2</sub> over N<sub>2</sub>.<sup>28</sup> After that, to our knowledge, no more MOFs have been synthesized from this cluster. Therefore, the effect of this cluster on CO<sub>2</sub> absorption and selectivity has not been studied. We have successfully designed CAU-8(Mg) by replacing Al with Mg cluster, thus, the CO<sub>2</sub> adsorption and selectivity of CAU-8(Mg) are also studied in this work. Similarly, the 2a and 2b structures are formed from CAU-8(Mg) by replacing the H<sub>2</sub>BPDC linker with H<sub>2</sub>ODA and H<sub>2</sub>TDA linkers, accordingly. The structure of 2b is displayed in Fig. 1d.

In the present work, Density Functional Theory (DFT) is accessed to accurately describe the structure of six MOFs. The formation energies are also scrutinized to determine whether they can be synthesized successfully. The reaction mechanisms between compounds to synthesize these materials are examined for the first time by Gaussian. Finally, the effects of axial molecules and linker lengths on CO<sub>2</sub> absorption and selectivity of these MOFs by Grand Canonical Monte Carlo (GCMC) are evaluated.

## II. Calculation method

Structural modeling of new MOFs is carried out in the Materials Studio package (Accelrys Inc.). The theoretical models are

optimized by the Forcite module using the Universal Force Field (UFF).<sup>33</sup> The quality of the geometry optimization in Forcite is set to fine. The geometry optimization algorithm is a smart algorithm which is a cascade of the steepest descent and quasi Newton methods. This is done using an iterative process of steepest descent in which the atomic coordinates and the cell parameters are adjusted until the total energy of the structure is minimized. These models are then used as initial structures for the full geometry optimization under periodic boundary conditions within the Vienna *Ab Initio* Simulation Package (VASP).<sup>34,35</sup> The generalized gradient approximation (GGA) functional and projector-augmented wave (PAW) method are employed.<sup>36,37</sup> The ion–electron interactions are described by Perdew, Burke, and Ernzerhof (PBE) exchange–correlation.<sup>38</sup> The variant of dispersion corrected developed by Grimme *et al.* PBE-D3(BJ) is adopted.<sup>39</sup> The periodic DFT optimizations are done using primitive cells for a reduction in the research expense and time (about 248–440 atoms per primitive cell). The  $2 \times 2 \times 2$  *k*-point optimizations are performed with an energy cut-off of 550 eV. The energy and force convergence criteria are set to  $10^{-5}$  eV and  $-0.01$  eV Å<sup>-1</sup>, respectively. Brillouin-zone integration is performed with a Gaussian broadening of 0.1 eV during all relaxations. In this paper, the PAW treatment of pseudopotentials uses the 3s electrons for Mg; 3s and 3p electrons for Al, S; 2s and 2p electrons for N, C, O, and 1s electron for H. All crystal structures are visualized using the VESTA program.<sup>40</sup>

The formation energy is the difference between the total energies of products and the total energies of the reactants, whereas the total energies of reactants obtained after optimizing them in a box of length 25 Å by VASP.

Various guest gas molecules are introduced to various locations of the channel pore, followed by a full structural relaxation. To obtain the gas binding energy, an isolated gas molecule placed in a supercell (with the same cell dimensions as the MOF crystal) is also relaxed as a reference. The static binding energy (at  $T = 0$  K) is then calculated using:

$$E_b = E_{\text{MOF}_{\text{gas}}} - E_{\text{MOF}} - E_{\text{gas}} \quad (1)$$

where,  $E_{\text{MOF}_{\text{gas}}}$ ,  $E_{\text{MOF}}$ ,  $E_{\text{gas}}$  refer to the total energy of the MOFs with one gas molecule, the system, and an isolated gas molecule, respectively. A negative value of  $E_b$  corresponds to energetically stable adsorption.

The accessible surface areas of MOFs are calculated using the atom volume and surface module in Materials Studio with the solvent radius set to 1.82 Å (kinetic radius of N<sub>2</sub>). Pore volumes are estimated using helium as the probing atom at 298 K and 1 bar in RASPA.

To investigate the reaction mechanism, the localized atomic-orbital-basis calculation method is employed. The geometries of all stationary points are fully optimized, without symmetry constraints, employing Perdew–Burke–Ernzerhof (PBE) functional<sup>38</sup> implemented in the Gaussian16 program. The 6-311g\*\* basis set is employed to construct the electronic wave-functions for all elements. The D3(BJ) correction is introduced to account for long-range van der Waals interactions.<sup>39</sup> The Quadratic Synchronous Transit (QST) approach is used to predict

transition states.<sup>41</sup> QST3 with three molecule specifications (a reactant, a product, and a guess transition state) can be used to computationally locate a transition state. The stability of the obtained structures is confirmed by vibration analysis.

The Grand Canonical ensemble Monte Carlo (GCMC) simulations performed using the RASPA 2.0 (molecular simulation software for adsorption and diffusion in flexible nanoporous materials) to determine the adsorbed number of gas molecules in MOFs.<sup>42,43</sup> The interactions of gas molecules with the MOFs are modeled using Lennard–Jones (LJ) 12–6 and Coulomb potentials. LJ parameters are taken from TraPPE-UA for MOFs (Table S2, ESI†),<sup>44–50</sup> which has been successfully applied in prediction adsorption in Al-MOFs.<sup>51,52</sup> Moreover, as in the case of MIL-53(Al), the LJ contributions from the Al atoms of Al-MOFs in this paper are not considered since Al atoms are shielded by the surrounding O atoms and the polarizability of Al atoms is much lower than those of O atoms.<sup>49</sup> This approach is applied successfully in MIL-68(Al) and MIL-91(Al).<sup>53,54</sup> The attractive vdW force exerted by the Mg atoms is not considered following the same criteria. For the van der Waals terms, the atom-based summation method is used with the cubic spline truncation. 12.0 Å is used as a cut-off radius for van der Waals terms. Ewald summation method with  $10^{-4}$  kJ mol<sup>-1</sup> accuracy is used to calculate electrostatic interactions. The atomic charges of MOFs are estimated using electrostatic potentials using a grid-based method (ChelpG)<sup>55</sup> (Table S3, ESI†), that has been widely used to predict isotherms of various guests in Al-MOFs.<sup>53,56</sup>

Simulations are performed with trial configurations consist of  $5 \times 10^5$  cycles for the equilibration and  $10^5$  cycles for the production step. For each cycle, Monte Carlo (MC) moves include attempts to insert, delete, exchange, rotate, translate, or recycle an adsorbed molecule. The probability of each type of move is equal in the simulations. All simulations are performed at a room temperature of 25 °C (298 K). The CO<sub>2</sub> molecule is represented by model proposed by Murthy.<sup>57</sup> CO<sub>2</sub> is modeled as a rigid linear triatomic molecule with three charged Lennard–Jones interaction sites located at each atom with a C=O bond length of 1.18 Å. CH<sub>4</sub> and N<sub>2</sub> are modeled by the united-atom models, in which it is treated as a single interaction center with its efficient potential. The potential parameters of CH<sub>4</sub>, N<sub>2</sub> are obtained from the TraPPE force field<sup>58</sup> and ref. 59.

The adsorption selectivities for binary mixtures of CO<sub>2</sub>/CH<sub>4</sub> and CO<sub>2</sub>/N<sub>2</sub> are defined by

$$S_{ij} = \frac{x_i}{x_j} \times \frac{y_j}{y_i}, \quad (2)$$

where  $x_i$ ,  $x_j$  is the mole fraction of component  $i$ ,  $j$  in the adsorbed phase; and  $y_i$ ,  $y_j$  is the mole fraction of component  $i$ ,  $j$  in the bulk, respectively.

### III. Results and discussion

#### A. Structural optimizations and electronic structures

The structural characteristics of all MOFs are presented in Table 1. The conventional cells of all structures are in the tetragonal crystal system with the  $I4_1/a$  space group (no. 88). The

**Table 1** The structural data of new MOFs. The data in brackets is the difference between simulation and experiment. The experimental data are taken from ref. 61 while data in the square bracket are taken from ref. 60

Number of atom/unit cell	496		592	752	624	720	880
Crystal system	Tetragonal						
Space group	I4 <sub>1</sub> /a (88)						
a = b (Å)	13.06	12.97 (-0.69%)	13.31	13.05	14.73	14.21	14.11
c (Å)	52.57	51.80 (-1.46%)	72.75	85.89	53.13	73.07	84.28
V (Å <sup>3</sup> )	8969.11	8706.37 (-2.93%)	12 890.76	14 627.99	11 518.99	14 748.51	16 780.87
Surface area (m <sup>2</sup> g <sup>-1</sup> )	1078 [1234]	1074.74	2359.65	1629.02	1160.69	2189.06	2029.22
Pore volume (cm <sup>3</sup> g <sup>-1</sup> )	0.48 [0.54]	0.49	0.80	0.68	0.58	0.74	0.69

experimental lattice parameters of CAU-8(Al) are  $a = 13.06$  Å, and  $c = 52.57$  Å.<sup>29,60</sup> These lattice constants in PBE-D3(BJ) are, respectively, 0.69% and 1.46% smaller than the experimental values. Apparently, the lattice parameters of CAU-8 obtained from the PBE-D3(BJ) method are well consistent with experimental observations. The calculated lattice parameters of CAU-8(Mg) are  $a = 14.73$  Å, and  $c = 53.13$  Å. As replacing the Al cluster with the Mg cluster in the CAU-8 structure, the lattice constant  $c$  increased slightly but the lattice constant  $a$  increased by 13.57%, resulted in an increase of the volume 32.31%. This is explained by the angle increase made by three sequential metal atoms in metal chains from 165.25° for Al to 174.13° for Mg and bond length between two sequential metal atoms. The Al–Al and Al–O(OH) distances in CAU-8(Al) are 3.27 Å and 1.84 Å while the Mg–Mg, Mg–O(DMSO) distances are about 3.69 Å and 2.21 Å, respectively, in CAU-8(Mg). Such a long-distance suggests that weak interaction can be present between Mg atoms. The lattice parameters of **1a** structure are  $a = 13.31$  Å and  $c = 72.75$  Å and for the **1b** structure are  $a = 13.05$  Å and  $c = 85.89$  Å which implies that alteration of longer linker makes the length of the  $c$ -axis increases significantly. This is similar when comparing lattice parameters between CAU-8(Mg), **2a** and **2b**. The lattice parameters of **2a** structure are  $a = 14.21$  Å and  $c = 73.07$  Å and for the **2b** structure are  $a = 14.11$  Å and  $c = 84.28$  Å.

The pore volume and accessible surface area of all MOFs are also listed in Table 1. The experimental surface area and pore volume of CAU-8(Al) in ref. 61 are 1078 m<sup>2</sup> g<sup>-1</sup> and 0.48 cm<sup>3</sup> g<sup>-1</sup> while these values are 1234 m<sup>2</sup> g<sup>-1</sup> and 0.54 cm<sup>3</sup> g<sup>-1</sup> in ref. 60. The calculated surface area and pore volume of CAU-8(Al) are 1074.74 m<sup>2</sup> g<sup>-1</sup> and 0.49 cm<sup>3</sup> g<sup>-1</sup>, similar to the reported experimental value from the former reference. It is shown that the surface area and pore volume of CAU-8(Mg) (1160.69 m<sup>2</sup> g<sup>-1</sup>, 0.58 cm<sup>3</sup> g<sup>-1</sup>) is larger than CAU-8(Al). The surface areas of modified MOFs also found that much greater than CAU-8(Al). The surface areas of **1a** and **1b** are calculated to be 2359.65 and 1629.02 m<sup>2</sup> g<sup>-1</sup> with pore volumes of 0.80 and 0.68 cm<sup>3</sup> g<sup>-1</sup>, respectively. The surface areas of **2a** and **2b** are 2189.06 and 2029.22 m<sup>2</sup> g<sup>-1</sup> while their pore volumes are 0.74 and 0.69 cm<sup>3</sup> g<sup>-1</sup>. The surface areas of these MOFs are similar to NOTT-125 (2447 m<sup>2</sup> g<sup>-1</sup>),<sup>62</sup> NJU-Bai-17 (2423 m<sup>2</sup> g<sup>-1</sup>),<sup>63</sup> but it is moderate in comparison with PCN-68 (5109 m<sup>2</sup> g<sup>-1</sup>).<sup>64</sup> Apparently, the surface area and pore volume of MOFs-containing ODA<sup>2-</sup> linker greater than those of MOFs-containing TDA<sup>2-</sup>. Additionally, the surface area and pore volume of MOFs-containing BPDC<sup>2-</sup> linker are smallest.

## B. Formation energy and reaction mechanism

The formation energy provides an excellent means of determining whether theoretically predicted phases are stable. This information can also serve as a guide for evaluating possible synthesis routes. We have calculated the formation energies by VASP based on the chemical reaction equations.

First, H<sub>2</sub>ODA linker may be synthesized from oxalyl chloride and aminosalicyclic acid

H<sub>2</sub>TDA linker may be formed by the reaction of terephthaloyl chloride and aminosalicic acid

Formation energies for (3) and (4) reactions are  $-240.80 \text{ kJ mol}^{-1}$  and  $-154.79 \text{ kJ mol}^{-1}$ , accordingly, implying that H<sub>2</sub>ODA and H<sub>2</sub>TDA linkers can be successfully synthesized.

The reactions of  $\text{Al}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$  and H<sub>2</sub>L (L = BPDC, ODA or TDA) may yield the CAU-8(Al), **1a**, **1b** crystal structures

Formation energies for CAU-8(Al), **1a** and **1b** are 3210.54, 3346.62 and 3135.20  $\text{kJ mol}^{-1}$ , respectively. The reactions of  $\text{Mg}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  and H<sub>2</sub>L (L = BPDC, ODA or TDA) may yield the CAU-8(Mg), **2a**, **2b** crystal structures

Formation energies for CAU-8(Mg), **2a** and **2b** are 1595.29  $\text{kJ mol}^{-1}$ , 1496.29  $\text{kJ mol}^{-1}$  and 1470.82  $\text{kJ mol}^{-1}$ . The results establish unambiguously that eqn (5) and (6) depict endothermic reactions for the Al-based and Mg-based MOFs, which is suitable for solvothermal reaction – used in synthesized CAU-8(Al).

To provide a fundamental understanding of CAU-8(Al), **1a** or **1b** formation, the reaction mechanisms from metal cluster and organic linkers are considered by Gaussian. The reaction states and the energy profile are shown in Fig. 2 and 3. The  $\text{Al}_2(\text{NO}_3)_5(\text{HNO}_3)(\text{OH})(\text{H}_2\text{O})_2$  model cluster shown in Fig. 2a.

First, as a linker (H<sub>2</sub>L) attempts to substitute a  $\text{NO}_3^-$ , O1 atom from the linker approaches closely, repel an H<sub>2</sub>O molecule and make a coordination bond to Al1 cation in the cluster. The binding energy of the Al cluster and linker is defined by

Fig. 2 (a) The model cluster; (b) the initial reactant, (c) transition state and (d) final state between  $\text{Al}_2(\text{NO}_3)_5(\text{HNO}_3)(\text{OH})(\text{H}_2\text{O})_2$  cluster and H<sub>2</sub>L linkers (L = BPDC, ODA or TDA). Atom color: Al, blue; C, brown; N, pale blue; O, red; H, pale pink; S, yellow.

Fig. 3 The energy profile of forming the bond between  $[\text{Al}_2(\text{OH})_2(\text{CO}_2)_4]_\infty$  cluster with H<sub>2</sub>L (L = BPDC, ODA or TDA) in unit of  $\text{kJ mol}^{-1}$ .

$$E_b = E_{\text{Al\_cluster-H}_2\text{L}} - E_{\text{Al\_cluster}} - E_{\text{H}_2\text{L}}. \quad (7)$$

The binding energies of Al cluster with H<sub>2</sub>BPDC, H<sub>2</sub>ODA, and H<sub>2</sub>TDA are  $-76.15$ ,  $-84.18$ ,  $-87.73 \text{ kJ mol}^{-1}$ , which shows the favorability of H<sub>2</sub>TDA. Such Al cluster – H<sub>2</sub>L complexes are regarded as initial reactant as shown in Fig. 2b. The proton H<sup>+</sup> remains to be associated with the linker molecule while attempts to make a weak bond of 1.68 Å with an O3 atom from

Fig. 4 (a) The model cluster; (b) the initial reactant, (c) transition state and (d) final state between  $\text{Mg}_2[\text{OS}(\text{CH}_3)_2]_3(\text{HNO}_3)_2(\text{NO}_3)_2$  cluster and H<sub>2</sub>L linkers (L = BPDC, ODA or TDA). Atom color: Mg, orange; C, brown; N, pale blue; O, red; H, pale pink; S, yellow.

Fig. 5 The energy profile of forming the bond between  $\{Mg_2[OS(CH_3)_2]_2(CO_2)_4\}_\infty$  cluster with  $H_2L$  ( $L = BPDC, ODA$  or  $TDA$ ) in unit of  $kJ\ mol^{-1}$ .

nearby  $NO_3^-$ . The distance between  $Al1-O1$ ,  $Al1-O3$ , and  $Al2-O2$  are about 1.87 Å, 1.97 Å, 5.85 Å. In those transition states as shown in Fig. 2c, the  $O3$  from  $NO_3^-$  departs from  $Al1$  and starts to link with  $H$  atom (from  $-OH$  of the linker) to form  $HNO_3$ , and the distance between  $Al1-O3$  is about 4.30 Å. The linkers move closely toward  $Al2$  whereas the  $Al2-O2$  distance is roughly 4.30 Å. The  $H_2BPDC$ ,  $H_2ODA$ ,  $H_2TDA$  transition states are found to be 21.44, 27.52, 16.74  $kJ\ mol^{-1}$  above the initial reactant. After that,  $HNO_3$  residue goes away and the linker is more motivated to attack the second  $Al$  site. The final state is when the  $Al2-O2$  bond is completed.  $HNO_3$  residue bonds  $O2$  *via* hydrogen bond of 1.85 Å. The  $H_2BPDC$ ,  $H_2ODA$ ,  $H_2TDA$  final states are found to be 34.03, 37.54, 26.03  $kJ\ mol^{-1}$  under the transition states.

Similarly, the hypothetical states and energy profile of forming the bond between  $Mg_2[OS(CH_3)_2]_3(HNO_3)_2(NO_3)_2$  cluster with  $H_2L$  as shown in Fig. 4 and 5. The binding energy of cluster and linker is given by the relation

$$E_b = E_{Mg_{cluster}-H_2L} - E_{Mg_{cluster}} - E_{H_2L} \quad (8)$$

The binding energies of  $H_2BPDC$ -cluster,  $H_2ODA$ -cluster, and  $(H_2TDA)$ -cluster are  $-53.76$ ,  $-55.73$ ,  $-57.27\ kJ\ mol^{-1}$  which shows the slight favorability of  $H_2TDA$ . At the initial stage, the proton  $H^+$  of linker make a weak bond of about 1.70 Å with an  $O3$  atom from nearby  $NO_3^-$ . The distance between  $Mg1-O1$ ,  $Mg1-O3$ , and  $Mg2-O2$  are about 2.05 Å, 2.13 Å, 5.92 Å.

The  $H_2BPDC$ ,  $H_2ODA$ ,  $H_2TDA$  transition states are found to be 22.50, 16.97, 15.63  $kJ\ mol^{-1}$  above the initial reactant. The  $H_2BPDC$ ,  $H_2ODA$ ,  $H_2TDA$  final states are found to be 50.49, 42.25, 39.44  $kJ\ mol^{-1}$  under the transition states.

### C. Gas storage and selectivity

In order to verify the reliability of the used force field, simulations of  $N_2$  adsorption at 77 K, 298 K, and  $CH_4$  at 298 K in CAU-8 are performed to compare against experimental data from the literature as displayed in Fig. 6. Our calculation result of  $CH_4$  isotherm at 298 K is basically identical to the experimental results. The calculated  $N_2$  isotherm at 77 K and 298 K are underestimated and slightly overestimated with the experimental results from ref. 60. The reason for the deviation is the idealized models used in the simulation, while the actual model is not perfect. This proved that the force field used in this work is able to predict the gas adsorption properties of MOFs with reasonable accuracy.

$CH_4$ ,  $N_2$ , and  $CO_2$  uptake isotherms of all MOFs are calculated at the temperature of 298 K and the pressure below 800 torr as indicated in Fig. 7. It can be seen that all isotherms are near linear. **1b** and **2b** show the best  $CO_2$  uptake among six MOFs, in particular, the  $CO_2$  uptake of **1b** and **2b** at 298 K and 800 torr are 4.32  $mmol\ g^{-1}$  ( $96.77\ cm^3\ g^{-1}$ ) and 3.66  $mmol\ g^{-1}$  ( $82.08\ cm^3\ g^{-1}$ ), accordingly. The  $CO_2$  uptake capacity of **1b** is even higher than those of MOFs based on linkers incorporating amide such as HNUST-1 ( $93.0\ cm^3\ g^{-1}$ ),<sup>65</sup> NOTT-125 ( $92.60\ cm^3$

Fig. 6 The comparison of the simulated and experimental (a)  $N_2$  isotherm at 77 K, (b)  $CH_4$  at 298 K and (c)  $CH_4$  at 298 K in CAU-8(Al).

Fig. 7 (a) CO<sub>2</sub>, (b) CH<sub>4</sub>, and (c) N<sub>2</sub> isotherms of the new MOFs at 298 K. In all cases, CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub> show near-linear isotherms.

g<sup>-1</sup>).<sup>62</sup> Meanwhile, the CO<sub>2</sub> capacities of CAU-8(Mg) and **2a** are the smallest with 2.05 mmol g<sup>-1</sup> (45.94 cm<sup>3</sup> g<sup>-1</sup>) and 1.74 mmol g<sup>-1</sup> (39.01 cm<sup>3</sup> g<sup>-1</sup>), respectively. The absorbed CO<sub>2</sub> amounts of Mg-based MOFs are smaller dramatically compared to Al-based MOFs. These lower gravimetric CO<sub>2</sub> capacities of Mg-based MOFs are mainly due to DMSO. Additionally, CO<sub>2</sub> adsorption follows the following order: TDA<sup>2-</sup> > BPDC<sup>2-</sup> > ODA<sup>2-</sup> for MOFs containing the same metal cluster.

By contrast, these MOFs adsorbed very limited amounts of CH<sub>4</sub> and N<sub>2</sub> under the same conditions. The CH<sub>4</sub> and N<sub>2</sub> uptakes of **1b** are 0.99 mmol g<sup>-1</sup> (22.18 cm<sup>3</sup> g<sup>-1</sup>) and 0.28 mmol g<sup>-1</sup> (6.19 cm<sup>3</sup> g<sup>-1</sup>) at 298 K and 800 torr, respectively. The CH<sub>4</sub> and N<sub>2</sub> absorptive capacity of **1b** are highest among six MOFs. The higher uptake capacity for CO<sub>2</sub> gas over CH<sub>4</sub>, N<sub>2</sub> in these MOFs may be associated with the quadrupole moment of CO<sub>2</sub> ( $-1.34 \times 10^{-39}$  cm<sup>2</sup>) which induces efficient interaction with the framework.

Given the increase in the adsorption amounts of these MOFs for CO<sub>2</sub> relative to CH<sub>4</sub> and N<sub>2</sub>, we further explore the adsorption selectivity for equimolar CO<sub>2</sub>-CH<sub>4</sub> and CO<sub>2</sub>-N<sub>2</sub> binary mixtures. The highest CO<sub>2</sub>/CH<sub>4</sub> selectivity of 5.65 is available in

**1b** for the 1 : 1 binary mixtures. Therefore, six MOFs are not suitable for use as adsorbent directly to separate CH<sub>4</sub> from CO<sub>2</sub>. The selectivity of CO<sub>2</sub>/N<sub>2</sub> in **1b** reaches 23.87 at 298 K and 800 torr, followed by **2b** (20.37). The significant selectivity of Al-based MOFs for CO<sub>2</sub> over both N<sub>2</sub> can be potentially implemented in the capture of CO<sub>2</sub> from landfill gas and natural gas. In both CO<sub>2</sub>/N<sub>2</sub> and CO<sub>2</sub>/CH<sub>4</sub> mixtures, the selectivities of CO<sub>2</sub> in MOFs comprising TDA<sup>2-</sup> ligands are higher than those in their parent MOFs CAU-8(Al) and CAU-8(Mg) while the opposite is true for MOFs comprising ODA<sup>2-</sup> ligands.

To gain better insight on the CO<sub>2</sub> position within the framework and the governing interactions responsible for resultant affinity, we performed the accurate interactions between the metal clusters and CO<sub>2</sub> molecules, organic linkers and CO<sub>2</sub> molecules. A single CO<sub>2</sub> molecule is placed in many different positions in the vicinity of the metal cluster or linker in **1b** and **2a** with various orientations, and relaxation of the MOF structure and CO<sub>2</sub> are made. The most dominant CO<sub>2</sub> molecules are identified by VASP as shown in Fig. 8. First, we consider the circumstance that one CO<sub>2</sub> molecule close to metal cluster. When CO<sub>2</sub> is close to Al cluster, O atoms of CO<sub>2</sub> contact with H atom of a hydroxyl and C atom of a carboxyl group of the linker; C atom of CO<sub>2</sub> contacts with O atom of a carboxyl group in the linker. The separation of (CO<sub>2</sub>)O...H(OH) is 2.09 Å. The binding energies between CO<sub>2</sub> and **1b**, **2a** are -30.59 kJ mol<sup>-1</sup> and -23.50 kJ mol<sup>-1</sup>, respectively. The significantly lower binding energy and CO<sub>2</sub> adsorption capacity found for DMSO-decorated MOFs has confirmed that DMSO molecules hinder CO<sub>2</sub> adsorption application.

In **2a**, CO<sub>2</sub> is situated on the top of the ODA<sup>2-</sup> linker wherein not only one O atom forms a -NH...O hydrogen bond (H...O = 2.70 Å) but also the C atom generates moderate O...C (3.34 Å) interaction with the oxalamide group (Fig. 8c). The O atom also contacts with C atom of phenyl ring (3.53 Å). The binding energy between CO<sub>2</sub> with ODA<sup>2-</sup> and TDA<sup>2-</sup> linkers are -38.27 kJ mol<sup>-1</sup> and -38.83 kJ mol<sup>-1</sup>. This simulation clearly verifies the crucial role of the amide group for high CO<sub>2</sub> loading.

The most dominant CH<sub>4</sub> molecules are identified by VASP as shown in Fig. 9. When CO<sub>2</sub> is in the vicinity of Al cluster, H atoms of CH<sub>4</sub> contact with O atom of hydroxyl and O atom of

Fig. 8 The main adsorption sites of CO<sub>2</sub> in the vicinity of (a) [Al<sub>2</sub>(OH)<sub>2</sub>(CO<sub>2</sub>)<sub>4</sub>]<sub>n</sub> cluster, (b) {Mg<sub>2</sub>[OS(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub>(CO<sub>2</sub>)<sub>4</sub>]<sub>n</sub> cluster, (c) ODA<sup>2-</sup> linker and (d) TDA<sup>2-</sup> linker.

Fig. 9 The main adsorption sites of  $\text{CH}_4$  in the vicinity of (a)  $[\text{Al}_2(\text{OH})_2(\text{CO}_2)_4]_\infty$  cluster, (b)  $\{\text{Mg}_2[\text{OS}(\text{CH}_3)_2]_2(\text{CO}_2)_4\}_\infty$  cluster, (c)  $\text{ODA}^{2-}$  linker and (d)  $\text{TDA}^{2-}$  linker.

carboxyl group. The separation of  $(\text{CH}_4)\text{H}\cdots\text{O}(\text{carboxyl})$  is 2.51 Å. When  $\text{CO}_2$  is in the vicinity of Mg cluster, H atoms of  $\text{CH}_4$  contact with S atom of DMSO and O atom of carboxyl group. The separation of  $(\text{CH}_4)\text{H}\cdots\text{O}(\text{carboxyl})$  is 2.94 Å. The binding energies between  $\text{CH}_4$  and **1b**, **2a** are  $-23.32 \text{ kJ mol}^{-1}$  and  $-20.48 \text{ kJ mol}^{-1}$ , respectively. When  $\text{CH}_4$  is close to linkers, H atoms of  $\text{CH}_4$  contact with O atom of amide groups. The separations of  $(\text{CH}_4)\text{H}\cdots\text{O}(\text{amide})$  are found 2.70 Å and 2.86 Å for **1b** and **2a**. The binding energies between  $\text{CH}_4$  and **1b**, **2a** in the case of  $\text{CH}_4$  vicinity linkers are  $-20.51 \text{ kJ mol}^{-1}$  and  $-17.07 \text{ kJ mol}^{-1}$ , respectively.

The most dominant  $\text{N}_2$  molecules are identified by VASP as shown in Fig. 10. When  $\text{N}_2$  is in the vicinity of the Al cluster, N atoms of  $\text{N}_2$  contact with O atom of hydroxyl and O atom of a carboxyl group. The separation of  $(\text{N}_2)\text{N}\cdots\text{O}(\text{hydroxyl})$  is 2.33 Å. When  $\text{N}_2$  is in the vicinity of the Mg cluster, N atoms of  $\text{N}_2$  contact with S atom of DMSO and O atom of carboxyl group. The separation of  $(\text{N}_2)\text{N}\cdots\text{S}(\text{DMSO})$  is 3.38 Å. The binding energies between  $\text{N}_2$  and **1b**, **2a** are  $-20.26 \text{ kJ mol}^{-1}$  and  $-19.08 \text{ kJ mol}^{-1}$ , respectively. When  $\text{N}_2$  is close to linkers, H atoms of  $\text{N}_2$  contact with O and H atom of amide groups. The separations of  $(\text{N}_2)\text{N}\cdots\text{O}(\text{amide})$  are found 3.17 Å and 2.95 Å for **1b** and **2a**. The binding energies between  $\text{N}_2$  and **1b**, **2a** in the case of  $\text{N}_2$  vicinity linkers are  $-19.08 \text{ kJ mol}^{-1}$  and  $-18.42 \text{ kJ mol}^{-1}$ , respectively.

Fig. 10 The main adsorption sites of  $\text{N}_2$  in the vicinity of (a)  $[\text{Al}_2(\text{OH})_2(\text{CO}_2)_4]_\infty$  cluster, (b)  $\{\text{Mg}_2[\text{OS}(\text{CH}_3)_2]_2(\text{CO}_2)_4\}_\infty$  cluster, (c)  $\text{ODA}^{2-}$  linker and (d)  $\text{TDA}^{2-}$  linker.

## IV. Conclusions

In summary, four new MOFs have been constructed by employing 4,4'-(oxalylbis(azanediyl)dibenzoic acid ( $\text{H}_2\text{ODA}$ ) and 4,4'-teraphthaloylbis(azanediyl)dibenzoic acid ( $\text{H}_2\text{TDA}$ ) containing amide groups ( $-\text{CO}-\text{NH}-$ ) with  $[\text{Al}_2(\text{OH})_2(\text{CO}_2)_4]_\infty$  and  $\{\text{Mg}_2[\text{OS}(\text{CH}_3)_2]_2(\text{CO}_2)_4\}_\infty$  clusters based on CAU-8 prototype. All MOFs exhibit positive formation energies, which are shown they are formed in the endothermic reactions. The proposed reaction mechanisms between Al and Mg clusters with organic linkers are suggested as follows: first, the linker attempts to approach closely and make a coordination bond to one metal cation in the cluster. Then, the proton  $\text{H}^+$  in the linker molecule attempts to make a bond with an O atom to form nitric acid. Finally, the linker attacks the second metal site and forms the connection between the cluster and the linker. **1b** has the highest absorption of  $\text{CO}_2$  among the materials with  $4.32 \text{ mmol g}^{-1}$  at 298 K and 1 atm. The  $\text{CO}_2/\text{N}_2$  selectivity of this material is highest (23.87), therefore, it is possible to apply in the capture of  $\text{CO}_2$  from landfill gas and natural gas. Compared with Al-based MOFs, Mg-based MOFs have lower absorptions and selectivities, which is attributed to the axial positions of DMSO. The utilization of longer linker  $\text{TDA}^{2-}$  instead of  $\text{ODA}^{2-}$  in MOFs construction results in materials greater  $\text{CO}_2$  absorption despite the larger surface area of MOFs-containing  $\text{ODA}^{2-}$  linker. It has been shown that  $\text{CO}_2$  tends to bind with the amide group in the linker in the materials.
