miRNA-mediated alteration of sulfatase modifying factor 1 expression using self-assembled branched DNA nanostructures†

 Kanchan Kumari,^{ab} Avishek Kar,^a Ashok K. Nayak,^a Sandip K. Mishra^c
 and Umakanta Subudhi^{id}*^{ad}

Sulfatase enzymes catalyze sulfate ester hydrolysis, thus deficiencies of sulfatases lead to the accumulation of biomolecules resulting in several disorders. One of the important sulfatases is estrone sulfatase that converts inactive estrone sulfate to active estradiol. Posttranslational modification of highly conserved cysteine residue leads to unique formylglycine in the active site of sulfatases being critical for its catalytic activity. The essential factor responsible for this modification of sulfatase is Sulfatase-Modifying Factor 1 (SUMF1). The role of estrone sulfatase is well evident in breast cancer progression. However, the function and regulation of SUMF1 in cancer are not studied. In the present study, for the first time, we have assessed the expression of SUMF1 in breast cancer and report the oncogenic behavior upon overexpression of SUMF1. Although increased expression or activity of SUMF1 is anticipated based on its function, the expression of SUMF1 was found to be reduced in breast cancer cells at both mRNA and protein levels. An estrogen receptor (ER) dependent expression of SUMF1 was observed and higher SUMF1 expression is associated with improved breast cancer patient survival in ER-positive cases. However, high SUMF1 expression leads to reduced median survival in ER-negative breast cancer patients. Putative binding sites for miRNAs-106b-5p, 128-3p and 148b-3p were found at 3'-UTR of SUMF1. Since self-assembled branched DNA (bDNA) structures have emerged as a highly efficient strategy for targeting multiple miRNAs simultaneously, we studied the alteration in SUMF1 expression using bDNA nanostructures with a complementary sequence to miRNAs. The findings suggest the involvement of co-regulators and repressors in miRNA-mediated SUMF1 expression in breast cancer cells and reveal the therapeutic potential of SUMF1 in endocrine-related malignancies.

Introduction

Estrogen is a principal hormone that plays an important role in the development and differentiation of the mammary gland.¹ Owing to its function, estrogen is critically involved in hormone-responsive breast cancer progression. The role of estrogen in breast carcinoma suggests the importance of targeting the synthesis and degradation of estrogen in the body. Cholesterol-derived C18 steroids or estrogen is found in three major natural forms namely estrone (E1), estradiol (E2), and estratriol (E3). All the forms of estrogen are present in serum and tissues at

different concentrations at different stages of life.² The most potent estrogen 17 β -estradiol (E2) is present as the main circulating hormone in pre-menopausal women and plays an important role during pregnancy.³ However, in post-menopausal women and during the menstrual cycle, E1 is present five to ten times more than E2 or E3.^{4,5} Estrone sulfates act as a precursor of estrogen and thus sulfates of estrone and estradiol have been found to present in huge quantities in breast cancer tissues.⁶ Metabolic responses of estrone sulfate are different in hormone-independent and dependent breast cancer cells.⁷ Estrone sulfates are hydrolyzed into estrone and finally into potent estradiol with the help of enzyme steroid sulfatases (STS). The activity of STS was found intense in hormone-dependent cell lines in comparison to hormone-independent.⁸ Breast carcinoma patients harbor significantly increased expression of STS suggesting its important role in the intratumoral synthesis of estrogen in post-menopausal women. Like other sulfatases, STS is activated when either cysteine or serine is post-translationally oxidized into formylglycine (fGly) in the active site of STS.⁹ This post-translational modification is specifically performed by the enzyme known as formylglycine

generating enzyme (FGE) which is encoded by the gene sulfatase modifying factor 1 (*SUMF1*).

SUMF1 gene is located in human chromosome 3, and plays a critical role in sulfatase enzyme activation, which is required for hydrolysis of sulfate esters. Mutation in *SUMF1* gene is known to affect several diseases including multiple sulfatase deficiency (MSD), chronic obstructive pulmonary disease *etc.*^{10–12} Nevertheless, the direct regulation of estrogen synthesis by *SUMF1* has been a contributing factor for the initiation of cancer in several tissues. For instance, estrone sulfate is proposed to be a prognostic marker for aggressive prostate cancer.¹³ Similarly, higher activity of estrogen sulfatase is evidenced in ovarian cancer^{14,15} and endometrium cancer.¹⁶ The role of estrone sulfatase is also well evident in breast cancer progression, however the direct role of *SUMF1* in breast carcinoma remains elusive. Although recent study reports *SUMF1* as a direct target of epigenetic molecule *EZH2* in breast cancer,¹⁷ no study has been done to understand the function and regulation of *SUMF1* in breast cancer. Keeping this as background, the present study explores the expression of *SUMF1* in breast cancer cell lines along with the effect of its overexpression on cancer cell proliferation. Overall, the study highlights the significance of *SUMF1* in estrogen synthesis and thus in endocrine-related carcinomas and proposes that targeting *SUMF1* may be of therapeutic potential.

Recently, non-coding RNAs including microRNAs are reported to play important role in gene expression. Since regulation of *SUMF1* by miRNAs is unexplored, the second objective of the present investigation is to identify and examine miRNA-mediated alteration in the expression of *SUMF1*. Nevertheless, the function and regulation of miRNAs have emerged as a new class of biomarkers for several diseases including cancer, and a potential tool for therapy.^{18–20} It is interesting to note that one miRNA can regulate the expression of multiple genes and on the other hand, the expression of an individual gene is controlled by multiple miRNAs. Thus, a suitable method of delivering multiple miRNAs is a prerequisite to understanding the function of any gene. In the last two decades, self-assembled branched DNA (bdDNA) nanostructures have evolved as powerful nanoscale engineered molecules for materials and biomedical applications.^{21–25} Moreover, bdDNA nanostructures have been proved to be an efficient strategy for microRNAs-based cancer therapy.^{26–28} Recently, our group has shown the efficacy of anti-miR-bdDNA nanostructures in regulating the expression of tumor suppressor *FOXO1* in breast cancer by synergistic down-regulation of three oncogenic miRNAs.²⁹ Biocompatible self-assembled bdDNA nanostructures increase the efficiency and bioavailability of therapeutics like miRNA or anti-miRNA by protecting from nuclease degradation and enhancing the half-life of oligonucleotides bound to the bdDNA nanostructures.^{30–33} Thus, in the current communication, we studied miRNA-mediated modification of *SUMF1* expression in breast cancer using bdDNA nanostructures. Particularly, the expression of miRNAs-106b-5p, 128-3p, and 148b-3p were thoroughly examined since the putative binding sites of these miRNAs were found at the 3'-UTR of *SUMF1*. An altered expression of *SUMF1* was noticed while modifying the expression of miRNAs using

bdDNA structures, but at the same time suggested an indirect method of regulation of miRNA-mediated expression of *SUMF1*. Nevertheless, the data suggested the participation of other molecular players in regulating *SUMF1* expression in breast cancer.

Methods

Cell culture

The human cell lines HEK293, MCF-7, MDA-MB-231, T47D, BT474, and SKBR3 were obtained from the National Repository of Animal Cell Culture (NCCS Pune, Maharashtra, India). HEK293, MCF-7, and BT474 cells were maintained in DMEM containing 10% fetal bovine serum supplemented with penicillin–streptomycin at 37 °C, 5% CO₂, and 95% humidity. Similarly, MDA-MB-231, T47D and SKBR3 cells were maintained in RPMI having 10% fetal bovine serum supplemented with penicillin–streptomycin at 37 °C, 5% CO₂, and 95% humidity. Normal breast epithelial cells MCF-10A was a kind gift of Prof. Annapoorni Rangarajan (IISc Bangalore). MCF10A was maintained as previously described¹⁷ to extract whole cell lysate.

Western blot

The cells were lysed in RIPA lysis buffer, electrophoresed on 10% SDS-polyacrylamide gel and the proteins were transferred onto polyvinylidene difluoride (PVDF) membrane. After blocking with 5% skimmed milk, the membrane was incubated with *SUMF1* (PAC879Hu01, Cloud-Clone Corp.) or α -tubulin (T5168, Sigma) primary antibody for overnight at 4 °C. The next day, the membrane was washed with TBS-T and incubated with HRP-conjugated anti-rabbit mouse secondary antibody for 1 h. The immunoblot was washed with TBS-T five times at 5 min intervals and developed using luminol (sc-2048, Santacruz) in a Chemidoc imaging system (Bio-Rad).

Self-assembled bdDNA nanostructures carrying anti-miR sequences

To study the effects of miRNA-106, 128, and 148 on the expression of *SUMF1*, single-stranded oligonucleotides for miRNA or anti-miR sequences (Table S1†) were transfected with transfection reagent (INTERFERin®, Polyplus). All the oligonucleotides used in the study were procured from Integrated DNA Technology, USA, and were directly used in the study without further purification or modification (Table S1†). Self-assembled bdDNA structures targeting miR-106, 128, and 148 were designed by replacing the four overhangs of the previously designed structure by our group^{29,30} with complementary sequences of miR-106, 128, and 148. The oligonucleotides scramble A, oligo B, oligo C, scramble D, anti-miR-106A, anti-miR-106D, anti-miR-128A, anti-miR-128D, anti-miR-148A, anti-miR-148D and anti-miR-106-128A were designed specifically and used in an appropriate ratio to form five different bdDNA structures such as bdDNA-scramble, anti-miR-bdDNA-106, anti-miR-bdDNA-128, anti-miR-bdDNA-148 and anti-miR-bdDNA-mix (Fig. S1†). Appropriate proportions of oligonucleotides were allowed to self-assemble in TAE/Mg²⁺ buffer at 95 °C for

10 min and then slowly cool down to 4 °C using thermal cycler (Bio-Rad) facilitating the formation of bDNA scaffold.^{30,32} The bDNA structures were checked for their integrity on 10% native polyacrylamide gel that was electrophoresed at 150 V for 1.5 h in TAE buffer. The gels were stained with ethidium bromide and imaged using the FluroChem E system (Cell Biosciences). 1 μM of oligonucleotides were used to prepare the bDNA structures from a stock of 100 μM. 50 μl of self-assembled bDNA structures was used to transfect the cells in 6-well tissue culture plates (final volume 2 ml) using lipofectamine 3000 according to the manufacturer's protocol. Fluorescein labeled oligo B was used in bDNA structures to check the transfection of bDNA structures (Fig. S1†). The pictures for fluorescence were captured at excitation 460 nm and emission 515 nm using Leica microscope (Leica DM3000).

RNA extraction, reverse transcriptase PCR and quantitative real time PCR

Total RNA was extracted from cells using the Trizol method. 1 μg of RNA was used to synthesize cDNA using a cDNA synthesis kit (18080051, Invitrogen). Reverse transcriptase PCR and qRT-PCR (Roche) was performed using gene-specific primers (Table S1†) and SYBR green (04707516001, Roche Diagnostics). The RT images were quantified using ImageJ software. qRT-PCR data were used to calculate the relative fold change for each gene compared to control using the value of cycle threshold (CT value). 18S rRNA amplification was used for the normalization of the data.

Correlation study and KM plotter analysis

Correlation values indicate the strength of association between two genes in terms of correlation coefficient (*r*) values that can be exit between +1 and −1. Negative and positive value indicates nature of association between genes. The value of +1 and −1 for correlation indicates a perfect linear relationship. To study the correlation for expression of SUMF1 and ERα in cancerous as well as non-cancerous breast cell lines and normal as well as primary breast tissues, the expression of SUMF1 and ERα was studied in the MERAV database that allows comparing the expression of multiple genes simultaneously in a large number of normalized microarray datasets.³⁴ The association of SUMF1 in estrogen receptor-positive and negative breast cancer cells was analyzed using Kaplan Meier plotter database that includes 3951 breast cancer patient samples from GEO datasets.³⁵

Crystal violet assay

For crystal violet assay, 5×10^4 cells were seeded in 6-well tissue culture plates and transfected with either empty vector pcDNA3.1 or pcDNA3.1 Neo(+) hSUMF1 (Addgene) using lipofectamine 3000 as per manufacturer's instructions (Invitrogen) after 24 h of attachment. After 72 h of transfection, the cells were fixed using 10% formalin at shaking condition for 20 min. The cells were washed with phosphate buffer saline (PBS) and stained with 0.1% crystal violet in water for 30 min. The cells were washed with PBS to remove the excess stain. The fixed and stained cells were air-dried, photographed, and dissolved in 10% acetic acid to quantify the stain. The absorbance was read at 570 nm in a plate reader (Varioskan™ Flash Multimode

Reader, Thermo Scientific). Percentage of viable cells = absorbance at 570 nm (pcDNA3.1 Neo(+) hSUMF1 transfected cells)/absorbance at 570 nm (pcDNA3.1 transfected cells) × 100.

Cell viability assay

For MTT assay, 3×10^3 cells were seeded in 96 well plates. After 24 h, the cells were transfected with either empty vector pcDNA3.1 or pcDNA3.1 Neo(+) hSUMF1 (Addgene) using lipofectamine 3000 as per manufacturer's instructions (Invitrogen). After stipulated time intervals, cell viability was determined by performing MTT assay. The MTT reagent was directly added to the growth medium containing cells at a concentration of 5 mg ml^{−1} and incubated for 4 h at 37 °C in the incubator. The medium containing MTT was carefully taken out and the formazan crystals thus formed were dissolved in 100% DMSO. The absorbance was read at 570 nm in a plate reader and the percentage of cell viability was calculated as described above.

Softwares used in the study

To examine the 3'-UTR of SUMF1 for putative miRNA binding sites, online tool Atlas of UTR Regulatory Activity (<http://aura.science.unitn.it>)³⁶ was used. The binding sites were further studied for binding scores using miRNA target prediction online tool TargetScan (http://www.targetscan.org/vert_72/).³⁷ The primers used for real-time PCR for specific microRNAs were designed using the online tool sRNAPrimerDB (<http://www.srnprimerdb.com/>).³⁸

Statistical analyses

The experiments were performed in three different breast cancer cell lines in two biological repeats. Throughout the study, two-tailed paired Student's *T*-test, one-way and two-way ANOVA was performed to test the statistical significance using the software GraphPad Prism v5.01. With *p* values **P* < 0.05, ***P* < 0.005 and ****P* < 0.001 were considered statistically significant.

Results and discussions

ERα-dependent expression and function of SUMF1

SUMF1 expression in breast cancer cell lines was analyzed using real-time PCR and western blot techniques. Reduced expression of SUMF1 was observed in breast cancer cell lines when compared to normal breast epithelial MCF10A cells at both protein and mRNA levels (Fig. 1a and b). Critical role in estrone sulfate hydrolysis suggests an ERα-dependent expression of SUMF1. To understand the correlation of SUMF1 expression with ERα, we analyzed the MERAV dataset in breast cancerous and non-cancerous cells as well as normal breast tissues and primary breast tumor tissues. Except for normal breast tissues, where a non-significant correlation was noticed (*r* = 0.06), a significant positive correlation was detected between SUMF1 and ERα expression in non-cancerous (*r* = 0.42) and cancerous breast cell lines (*r* = 0.21) as well as in primary breast tumor tissues (*r* = 0.2) (Fig. 1c–f). The positive correlation between ERα and SUMF1 suggests increased expression of ERα in presence of increased SUMF1 in cancer. Further, to study the relevance of SUMF1 in breast cancer patient survival, KM plotter analysis

was done. Interestingly, higher SUMF1 expression was found to be associated with improved breast cancer patient survival in ER-positive cases. However, in ER-negative breast cancer patients, high SUMF1 expression leads to significantly reduced median survival (Fig. 1g and h). The opposite relation of high SUMF1 expression with patient survival in ER α positive and negative breast cancer indicates its critical role in estrogen level and its pathological consequences. In terms of receptor status, MCF-7, MDA-MB-231, SKBR3, BT474 are ER $^+$ /PR $^+$ /HER2 $^+$, ER $^-$ /PR $^-$ /HER2 $^{-/+}$, ER $^-$ /PR $^-$ /HER2 $^+$, ER $^-$ PR $^+$ /HER2 $^+$ respectively.³⁹

Overexpression of SUMF1 leads to increased breast cancer cell proliferation

To access the role of SUMF1 in breast cancer, SUMF1 was overexpressed using pcDNASUMF1 in breast cancer cells and performed proliferation assays. Cancer cells with overexpressed SUMF1 showed increased cell proliferation. Crystal violet assay displayed an increased number of viable cells in MCF-7, SKBR3, and BT474 breast cancer cells upon SUMF1 overexpression (Fig. 2a and b). Similar to MDA-MB-231, both SKBR3 and BT474 are ER negative breast cancer cell lines. A similar kind of results was

Fig. 1 Expression of SUMF1 in breast cancer: (a) immunoblot shows the expression of SUMF1 in breast cancer cell lines including HEK293. (b) Graph shows the differential expression of SUMF1 mRNA in cell lines as observed in qRT-PCR. The correlation graphs shows the association of SUMF1 with ER α expression in (c) non-cancerous, (d) breast cancer cell lines, (e) normal breast tissues as well as in (f) primary breast tumors. The graphs were prepared using the raw normalized data in MERAV database. (d) Graphs display the association of SUMF1 expression with overall breast cancer patient survival as analyzed using Kaplan Meier plotter in (g) ER positive and (h) ER negative breast cancer.

obtained in MTT assay performed in MCF-7 and SKBR3 at three different time points. Percentage of viable cells were significantly increased after 24 h, 48 h, and 72 h of incubation in cells provided with exogenous SUMF1 (Fig. 2c and d). Irrespective of the receptor status of the cell lines, exogenous expression of SUMF1 leads to increased proliferation. Since cell proliferation is directly correlated with the overexpression of SUMF1, we are excited to check the possible regulation of SUMF1 by miRNA.

3'-UTR of SUMF1 contains binding sites for miRNAs 106, 128 and 148 which are differentially expressed in breast cancer cell lines

Expression of SUMF1 in breast cancer cell lines was found to be reduced in comparison to normal breast epithelial cells, however, its overexpression leads to increased cancer cell proliferation. At the same time, increased expression of SUMF1 in ER-positive breast cancer patients is significantly associated with improved patient survival opposite to ER-negative patients. To understand the reason behind the reduced expression of SUMF1 in ER-positive breast cancer cells, we were interested to know if any miRNA is known to regulate their expression. miRNAs are widely known to repress its target mRNA by binding to its 3'-UTR leading to mRNA degradation and translation repression.⁴⁰ With no previous reports, we went on to analyze the 3'-UTR of SUMF1 using the online tool Atlas of UTR Regulatory Activity that predicts putative miRNA binding sites at UTRs (Fig. S2†). Binding sites for miR-106, 128, and 148 was found on 3'-UTR of SUMF1 (Fig. 3a). Using miRDB, the target

scores for miR-106 and 148 was found to be 77, and 59 respectively. However, miRDB showed no binding of miR-128 on SUMF1. Therefore, to study the miRNA-mediated SUMF1 regulation, we first examined the expression of the miRNA-106, 128, and 148 in different breast cancer cell lines. On one hand, miRNA-106a-5p displayed an oncogenic role in breast cancer cells by regulating PTEN (phosphatase and tensin homolog),⁴¹ AKT, p53, and BCL2.⁴² Similarly, by regulating another tumor suppressor gene hypermethylated in cancer 1 (HIC1), miRNA-128 is found to accelerate the breast tumor growth in xenograft mice.⁴³ On the other hand, miRNA-148 play important role in chemoresistance by regulating ER α ,⁴⁴ BCL2,⁴⁵ Wnt-1 (ref. 46) leading to reduced breast cancer cell migration, inhibition, and increased apoptosis. Importantly, we observed a differential expression of miRNA-106, 128, and 148 in breast cancer cells compared to normal breast epithelial cells (Fig. 3b-d). Compared to normal breast epithelial MCF10A cells, the expression level of miR-106 was found significantly high in MCF-7 breast cancer cells. Similarly, BT474 and T47D breast cancer cells were found to harbor an increased level of miR-128 and miR-148 respectively. Thus it is clear that the differential expression of miRNAs in each breast cancer cell lines has a unique way of regulating SUMF1. To understand further agonist and antagonist of miRNAs were transfected and the expression of SUMF1 was observed.

Transfection of anti-miR or miR sequences modifies the expression of SUMF1 in breast cancer cells

To investigate if these miRNAs target SUMF1, we transfected the cells with oligonucleotides of miRNA-106, 128, and 148 and

Fig. 2 SUMF1 increases cell proliferation in breast cancer. (a) Picture shows the result of crystal violet assay performed upon SUMF1 over-expression in MCF-7, SKBR3 and BT474 breast cancer cell lines. (b) Graph shows the quantification of crystal violet assay displaying the percent of viable cells in control and SUMF1 over-expressed cells. The effect of SUMF1 ectopic expression on breast cancer cell growth after 24 h, 48 h and 72 h of transfection using MTT assay performed in (c) MCF-7 and (d) SKBR3 breast cancer cells. Student *t*-test and one-way ANOVA was used for statistical analysis **P* < 0.05, ***P* < 0.01, ****P* < 0.001.

Fig. 3 Expression of miRNA-106, 128 and 148 in different breast cancer cell lines. (a) The picture shows the binding sequences of miRNA-106, 128 and 148 to the 3'-UTR of SUMF1. The relative expression of (b) miRNA-106 (c) miRNA-128 and (d) miRNA-148 in various cell lines. Student *t*-test and one-way ANOVA was used for statistical analysis $**P < 0.01$, $***P < 0.001$.

checked the mRNA expression of SUMF1 by reverse transcriptase PCR. An increased expression of SUMF1 was observed in miR-106 transfected MCF-7 and BT474 cell lines (Fig. 4a, b, S3a and b†). Nevertheless, an upregulation of SUMF1 was also noticed in BT474 transfected with miR-128 and 148 (Fig. S3a and b†). On the other hand, a significant downregulation of SUMF1 was observed when BT474 is cotransfected with all the three miRNA (miRNA-mix). Thus, these three miRNAs are unable to show a synergistic effect on SUMF1 expression in BT474. In contrast, expression of SUMF1 was upregulated in HEK293 cells only when all three miRNA mimics were transfected. Hence, the expression of SUMF1 with respect to the transfection of miRNA-106, 128, and 148 are opposite for HEK-293 and BT474. To check the expression status of miRNAs in MCF-7 transfected cells, we performed quantitative real-time PCR (qRT-PCR). As shown in Fig. 4c–e expression of all three miRNAs were significantly upregulated in respective transfected samples and in the combination which suggested that the expression level of SUMF1 as observed in Fig. 4a is due to the altered level of miRNAs. Further to validate the miRNA-mediated above observation, we transfected antimiR oligonucleotides and checked the expression of SUMF1 and miRNAs. Interestingly, a non-significant but reduced trend of SUMF1 expression was observed in both MCF-7 as well as HEK293 cells (Fig. 4f and g). A non-significant reduction in the expression of miRNAs was also detected in antimiR oligonucleotides transfected samples. Expression of both miRNA-128 and 148 was down-regulated after transfection with antimiR oligonucleotides, whereas no significant change was observed in the

expression of miRNA-106 (Fig. 4h–j). The use of antisense oligonucleotides complementary to miRNA sequence has been widely used to target miRNAs. As per expectation, antisense oligonucleotides (ASO) must bind to the target miRNA and stimulate RNase dependent degradation of target RNA. Moreover, modified ASO which is preferred over unmodified ASO may show different adverse effects on miRNA activity such as sterically blocking the target miRNA leading to reduced accessibility of antimiR-miRNA duplex to RNase H.^{47,48} Recently, bdNA nanostructures have been proved to provide a stable and efficient approach to targeting miRNA. Upon analyzing the miRNA database miRDB, we hypothesized that possibly an expression of SUMF1 is regulated by hsa-miR-106b-5p, has-miR-128-3p, and hsa-miR-148b-3p. Therefore, self-assembled bdNA nanostructures containing antimiR sequences for miR-106, 128, and 148 were used to study the expression of SUMF1.

bdNA nanostructures containing antimiRs significantly reduced the expression of miRNAs

We have designed bdNA structures containing antimiR sequences for miRNA-106, 128, and 148 as previously described by our group.²⁹ The integrity of the structure was checked using native polyacrylamide gel. Individual oligonucleotides showed a band with good intensity and the oligo bound to complementary sequences (AB and CD di-oligo complex) exhibited retarded migration in nPAGE (Fig. 5a). As expected, oligonucleotides like A, C, or B, D or A, D were unable to form di-oligo complex unlike oligos A, B or C, D. Then bdNA-scr, antimiR-

Fig. 4 SUMF1 expression alters with miRNA-106, 128 and 148 modifications. (a) Agarose gel shows the SUMF1 expression in breast cancer cells transfected with miRNA-106, 128 and 148 as observed in RT-PCR. (b) Relative expression of SUMF1 was quantified using ImageJ taking 18S for normalization. Graphs show the relative fold change in expression level of (c) miRNA-106 (d) miRNA-128 and (e) miRNA-148 in MCF-7 cells transfected with miR oligonucleotides. (f) Expression of SUMF1 in cells transfected with anti-miR oligonucleotides against miR-106, 128 and 148 is displayed in the agarose gel as obtained using RT-PCR. (g) Relative expression of SUMF1 using ImageJ quantification against the expression of 18S. (h–j) Relative fold change in expression of (h) miRNA-106 (i) miRNA-128 and (j) miRNA-148 in MCF-7 cells transfected with anti-miR-106, 128, and 148 as observed in real time PCR. Student *t*-test and one-way ANOVA was used for statistical analysis **P* < 0.05, ***P* < 0.01, ****P* < 0.001.

bdNA-106, bdNA-128, bdNA-148, and bdNA-mix were self-assembled and a clear intense band was observed near the loading wells which suggest the formation of stable self-assembled bdNA structure (Fig. 5). Before transfection, we are excited to examine the specific binding of miRNA sequences to the anti-miR-bdNA structures. Interestingly, a notable shift in the band was observed that indicated the successful binding of miR sequences to the respective anti-miR binding sites in bdNA

structures (Fig. 5d). Nevertheless, with an increase in miRNA numbers the bound product to the anti-miR-bdNA-mix were also more retarded which ensures the efficient binding of multiple miRNAs. To study the efficiency of self-assembled bdNA upon single oligonucleotides, anti-miRNA oligonucleotides and anti-miR-bdNA structures were transfected with equal concentrations into the MCF-7 and HEK-293 cells, and the expression of miRNAs and SUMF1 was studied by qRT-PCR.

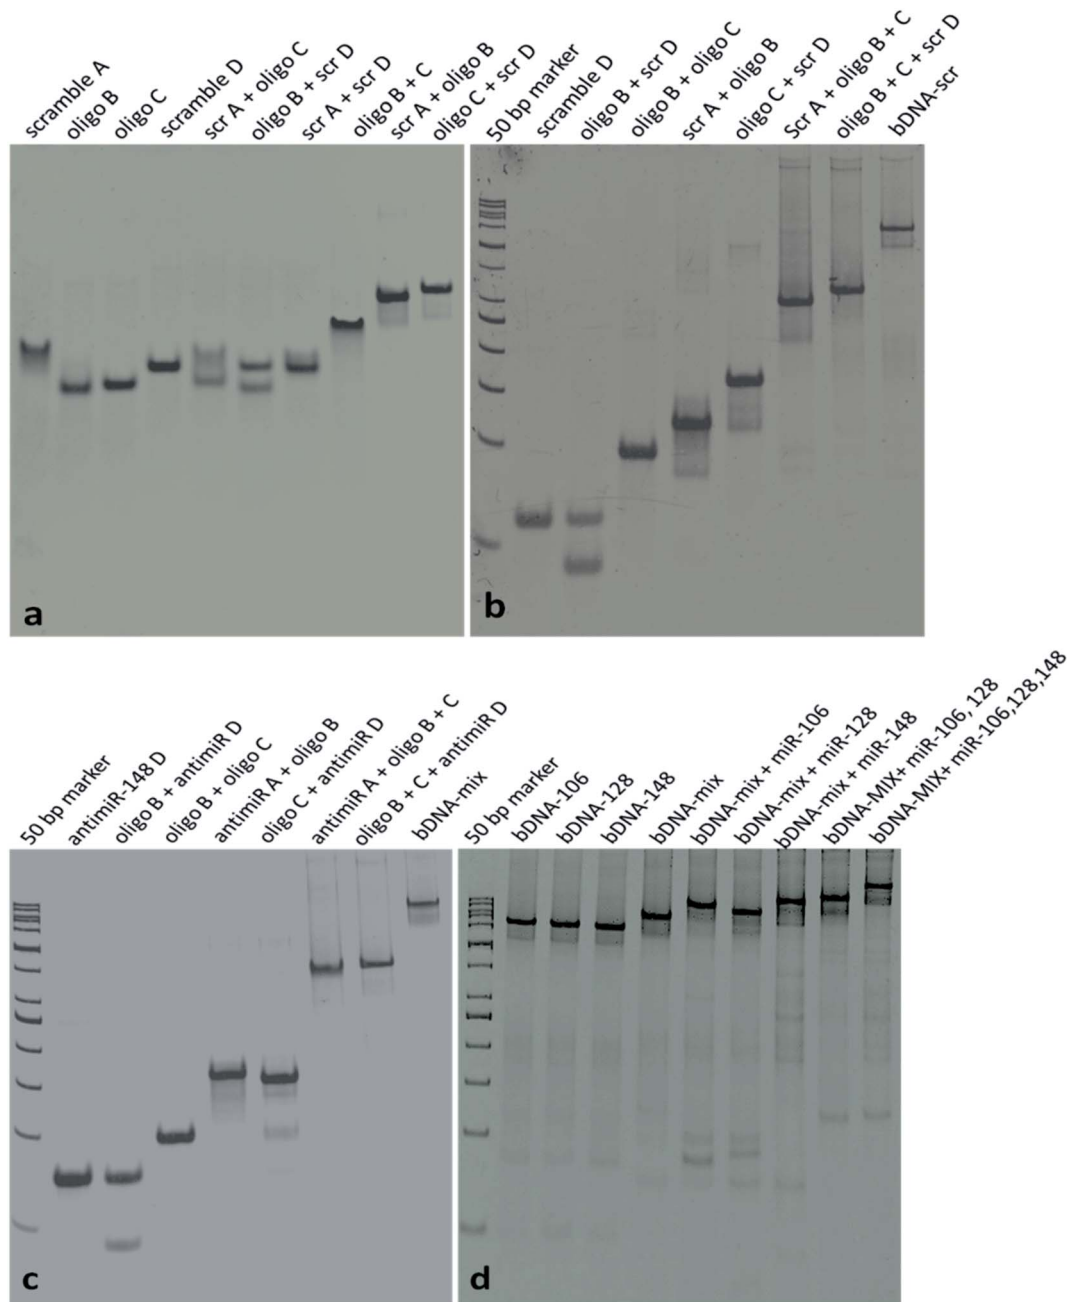

Fig. 5 Self-assembly among oligonucleotides to form stable bDNA structures. (a) Native-PAGE gel image shows the intensity and integrity of single and di-oligonucleotides used to form various bDNA structures. Oligos having non-complementary sequences never bind to each other, whereas oligos with complementary sequence form a stable di-oligo complex. (b) Gel image shows the intensity and integrity of single and di-oligonucleotides used to form bDNA scramble (c) gel image displays the binding of oligonucleotides to form bDNA-mix structures containing binding sites for anti-miR sequences for miRNA-106, 128 and 148. (d) Gel image displays the binding of oligonucleotides to form bDNA structures (bDNA-106, bDNA-128, bDNA-148 and bDNA-mix) containing anti-miR sequences for miRNA-106, 128 and 148. Binding of miRNAs to their respective anti-miR sequences present in the overhangs of bDNA structures leads to shift in the band position of the bDNA in the native PAGE.

SUMF1 expression is reduced upon transfection with anti-miR-bDNA structures

Self-assembled anti-miR-bDNA structures which contain anti-miR sequences for miR-106, 128, 148 in overhangs were used to study the expression of SUMF1 (Fig. S1†). Fig. 6a shows the brightfield images of fluorescein labeled bDNA transfected MCF-7 cells. Reduced expression of SUMF1 was evidenced in MCF-7 cells transfected with anti-miR-bDNA-106, 128, and 148

but not with anti-miR-bDNA-mix (Fig. 6b and c). Significant reduction in the expression of miRNA-106, 128, and 148 was also detected in MCF-7 cells transfected with respective anti-miR-bDNA nanostructures (Fig. 6d–f). It was interesting to see that the expression of other miRNA was also affected along with the bDNA transfected for specific miRNA. For instance, expression of miRNA-128 and 148 was significantly reduced in cells transfected with anti-miR-bDNA-128 and anti-miR-bDNA-

mix (Fig. 6e and f). Similarly, expression of all three miRNAs was reduced in MCF-7 cells transfected with anti-miR-bDNA-106 and 148. These results suggest that the expression of miRNA-106 and 148 have a positive correlation with the expression of SUMF1 in MCF-7 cells. When a decline in expression of miRNA-106 and 148 was observed, the expression of SUMF-1 also decreases concomitantly. Possibly miRNA-106 and miRNA-148 block the expression of a repressor protein that plays an important role in SUMF-1 expression. Thus, when anti-miR-bDNA-106

and 148 transfected the level of miRNA-106 and 148 decreases in MCF-7 and in turn the expression of repressor protein increases which result into down-regulation of SUMF-1. Similarly, the expression of SUMF-1 is significantly down-regulated in HEK-293 and BT474 transfected with anti-miR-bDNA-106, 128 and mix nanostructures (Fig. 6b, c, S3c and d†). The results suggest that expression of miRNAs is different in different cell lines and they differentially regulate the target gene. In this study for the first time, we demonstrate that anti-miR-bDNA-106, 128 and 148 down-

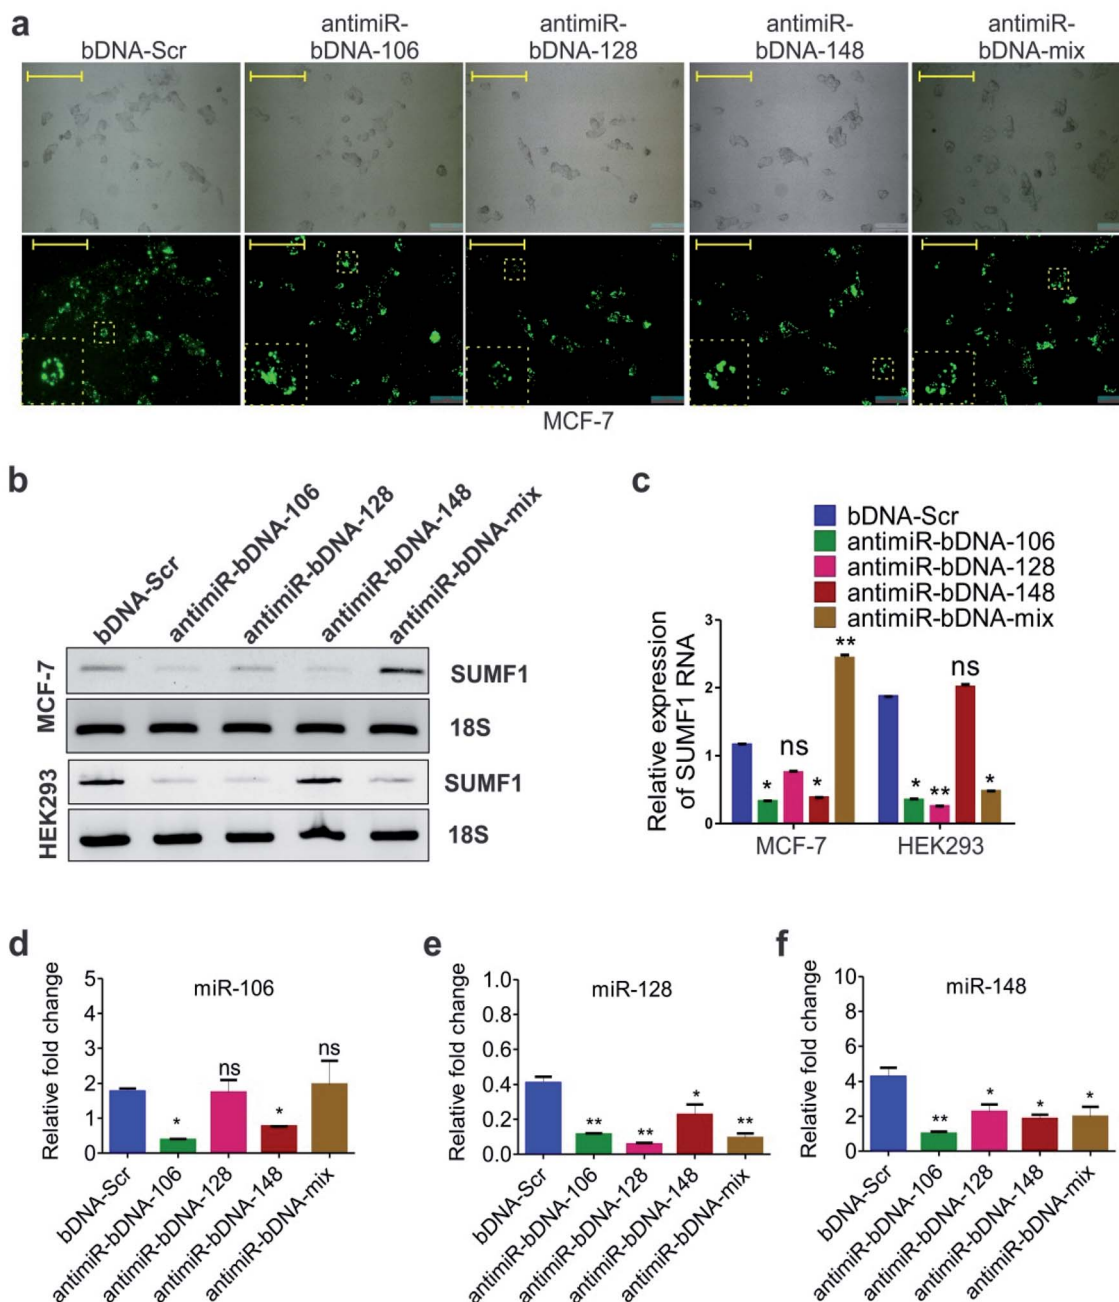

Fig. 6 Expression of SUMF1 is reduced with effect of transfection with anti-miR-106, 128 and 148. (a) Brightfield images and fluorescence images (20 \times) shows the successful transfection of bDNAs in MCF-7 breast cancer cells. The images were captured 24 h post-transfection. (b) RT data revealed reduced SUMF1 expression in MCF-7, and HEK293 cells transfected with anti-miR-bDNA-106, 128 and 148 in agarose gel. (c) Relative expression of SUMF1 after normalization with 18S using ImageJ software. (d–f) The bar graphs displays the relative fold change in expression of (d) miRNA-106 (e) miRNA-128 and (f) miRNA-148 in transfected MCF-7 cells as observed in qRT-PCR. Student *t*-test and one-way ANOVA was used for statistical analysis ***P* < 0.01. Scale bar 100 μ m.

regulate the expression of SUMF1 by releasing the SUMF1 repressor. Interestingly, other important targets of hsa-miR-106, 128, and 148 can be examined to understand the regulation of SUMF1 through miRNA.⁴⁵

Regulation of gene expression in cancer is an intricate process that involves genetic, epigenetic as well as environmental factors. Action of estrogen hormone is one of the metabolic factors that critically involved in the breast cancer development and progression. Synthesis and degradation of hormone estrone is regulated by large number of molecular players that are in turn regulated at both transcriptional and post-transcriptional level. Sulfate esters of estrogen act as reservoir of estrogen and are hydrolyzed by the enzyme estrogen sulfatases or steroid sulfatases that are elevated in breast carcinoma cases. Role of SUMF1 in activation of sulfatases is well evident in cases of multiple sulfatase deficiency where SUMF1 is mutated.^{49,50} If we analyze the SUMF1 promoter (3 kb upstream), binding sites of several important transcription factors is comprehended (Table S2†). The list includes critical transcription regulators such as ER α , ER β , p53, Nrf2, AP-1, Sp-1, p300, E2F, NF-AT1, FOXO3a, GATA3, NF-Y and cMyc. Regulation of SUMF1 by these transcription factors will be interesting to study in future. Overall, miRNA-106, 128 and 148 regulates SUMF1 expression indirectly and further research in this area will identify the direct regulators of SUMF1 in cancer.

Conclusions

Here in this study, for the first time we show the differential expression of SUMF1 in breast cancer cell lines and its association with overall breast cancer patient survival which was found to be dependent on estrogen receptor alpha. Moreover, its ectopic expression was found to have stimulatory role on breast cancer cell proliferation. SUMF1 expression was found to be increased with transfection of oligonucleotides of miRNA-106, 128 and 148. Moreover, a reduced expression of SUMF1 was noticed upon transfection with bDNA nanostructures containing anti-miR sequences of the miRNAs. This indicated the participation of other molecular players similar to estrogen receptor alpha that determines the association of SUMF1 expression with patient survival and that anticipates further research in this area.

Author contributions

K. K. and U. S. designed the project. K. K., A. K., and A. K. N. performed the experiments and acquired the data. K. K., S. K. M. and U. S. drafted and critically reviewed the manuscript. All the authors read and approved the manuscript submission.

Conflicts of interest

The authors declare no potential conflicts of interest.

Acknowledgements

Authors are thankful to the Council of Scientific & Industrial Research (CSIR) and Department of Biotechnology (DBT), Government of India, New Delhi for supporting the work.
