# Access and modulation of substituted 1-methyl-1,6-dihydropyrazolo[3,4-c]pyrazoles†

Nicu-Cosmin Ostache,<sup>ab</sup> Marie-Aude Hiebel,<sup>a</sup> Adriana-Luminița Fînaru,<sup>b</sup> Hassan Allouchi,<sup>c</sup> Gérald Guillaumet<sup>a</sup> and Franck Suzenet<sup>ab</sup>\*

Despite the pharmacological potential of the pyrazolo[3,4-c]pyrazoles, only a few methods of preparation and direct functionalization of this moiety have been described. We report herein a convenient design of new pyrazolo[3,4-c]pyrazoles with a high therapeutic impact. The effective chosen strategy consists of hydrazine condensations and C–N Ullmann-type cross-coupling reactions with microwave activation. Moreover, chemoselective bromination of the newly formed bipyrazoles followed by Suzuki–Miyaura cross-coupling reactions allowed the synthesis of a variety of modulated heterobicycles.

## Introduction

Fused bicyclic heterocycles are ubiquitous in nature. The most prominent include biological macromolecules (DNA and RNA with their purine bases), proteins and peptides, as well as physiologically important biomolecules (serotonin, melatonin *etc.*).<sup>1</sup> In contrast, bicyclic heterocycles containing a nitrogen–nitrogen (N–N) bond are relatively rare in nature, but nonetheless prevalent in the pharmaceutical industry.<sup>2</sup> Such a class is well represented by the ring-contracted [5:5] bicyclic aromatic rings. Among this group, the pyrazolo[3,4-c]pyrazole nucleus stands out from the little attention it was given, despite previous reports of interesting biological activities.<sup>3–7</sup> Differences in the distribution of ring electron densities and in spatial orientation between [5:5] bicyclic aromatic rings and their [6:5] and [6:6] analogs could explain these interesting therapeutic effects.<sup>8</sup>

The synthesis of this bicyclic scaffold are scarcely found in the literature and are almost exclusively based on an existing pyrazole motif.<sup>9–11</sup> The desired bicyclic framework is afterward obtained either according to a mononuclear heterocyclic rearrangement<sup>1,8</sup> (known as Boulton–Katritzky rearrangement – Route A), an annulation strategy (Route B)<sup>12–17</sup> or other miscellaneous methods (using isothiocyanates,<sup>18</sup> nitrilimines,<sup>9</sup> aryl-semicarbazides<sup>19</sup> or 2-cyano-*N*-methyl-acrylamide<sup>20</sup>).

These methods, while apparently abundant, exhibit nonetheless several major limitations such as a narrow functional group tolerance, a lack of further modulation, a non-convergent strategy, multiple steps and complex starting materials (Scheme 1a). In order to overcome these difficulties, we hereby present an efficient one-pot approach and a robust process in the design of novel pyrazolo[3,4-c]pyrazoles, using the 5-bromo-1-methyl-1*H*-pyrazole-4-carbaldehyde<sup>21,22</sup> (**1**) (Scheme 1b). The first modulation arises from the use of diverse aromatic hydrazines, followed by a C–N Ullmann-type cross-coupling reaction under microwave irradiation, leading to compound **2**. Chemoselective bromination of the formed bipyrazole ensures the formation of further functionalized scaffolds by a Suzuki–Miyaura cross-coupling. The main text of the article should appear here with headings as appropriate.

## Results and discussion

The one-pot sequence for the synthesis of the bipyrazole **2a** relies on previous studies on similar heterocycles.<sup>23–26</sup> The

condensation step occurred quantitatively with a slight excess of phenylhydrazine. After a change of solvent and addition of the Ullmann-type catalysts, the expected fused heterocycle was obtained in an encouraging yield (Table 1, entry 1).

Increasing the reaction temperature to 150 °C allowed a significant yield improvement (Table 1, entries 2). The amount of catalyst and ligand was investigated and reducing to half the initial quantities lead to an identical yield, alongside traces of starting material (Table 1, entries 3–4). The chlorinated analogue was tried but gave lower yield. In order to increase the conversion to its fullest, the reaction time was doubled (Table 1, entry 5). Finally, the sole use of copper catalyst was proven to be

essential for the cyclization giving access to the optimized reaction conditions (Table 1, entries 6–8).

Next, the scope and generality of the cyclization step were examined (Table 2). Nonetheless, the condensation of various monosubstituted aromatic hydrazines requires two different reaction conditions, depending on the nature of the arylhydrazines. When salt free arylhydrazines are involved, a catalytic amount of acid is used (1) while under their hydrochloride salt form, a stoichiometric amount of sodium acetate is required (1\*).

Hydrazines bearing electron-donating (Table 2, entries 1–3) or electron-withdrawing groups (Table 2, entries 4 and 5) were equally well tolerated since the corresponding pyrazolo[3,4-c]pyrazoles (**2a–e**) were isolated with good to excellent yields over the two steps. Regarding the fluoro substituent position (*ortho*, *meta* or *para*) on the aromatic ring, a slight effect was observed in favor of the meta position (Table 2, entries 6–8). Furthermore, heterocyclic hydrazines were found to be an accessible partner for the annulation step (Table 2, entry 9).

The scope of the reaction is unfortunately limited to aryl hydrazines since hydrazine lead to a *bis*-condensated compound, and alkylhydrazines to degradation or a lack of conversion.

We afterwards focused our attention on the insertion of a second point of diversity through a bromination step followed by a Suzuki–Miyaura cross-coupling reaction. The bromide was selectively introduced on C3.<sup>27</sup> The ratio of the mono-brominated (**3a**) and dibrominated (**3a'**) compounds was optimized through diverse reaction conditions (Table 3).

A partial conversion was noticed, with the formation a mixture of a mono- and dibrominated analogue when using a slight excess of halogenation agent (Table 3, entry 1). Determined by this result, the amount of NBS was increased up to 1.5 equivalents, action that lead to a total conversion and an increased yield of the monobrominated bicycle of 69% (Table 3, entries 2 and 3). In order to render the reaction faster, conventional heating was replaced by microwave irradiation. Better results were attained after only 2 hours of reaction time (Table 3, entry 4).

After establishing the best reaction conditions which allow the major formation of the monobrominated bipyrazole, the

<sup>a</sup> Isolated yield after silica gel chromatography purification.

impact of the electronic nature of a substituent on the aromatic moiety was investigated (Table 4).

When the substituent present on the aromatic ring is electron-rich in nature, 15 minutes of microwave irradiation and a stoichiometric amount of NBS allowed the synthesis of the halogenated compound with a correct yield, alongside traces of starting material, as well as an inseparable mixture of mono and dibrominated by-products (Table 4, entry 1). Neither a slight bromination agent excess, nor longer reaction times allowed results superior to 50% (Table 4, entries 2 and 3). However, switching to conventional heating lead to the identification of the optimal conditions, as well as obtaining a slightly higher yield of the expected molecule of 55% (Table 4, entry 4). When the aromatic ring from position 6 is substituted by an electron-withdrawing substituent, the bromination reaction performed under microwave irradiation turned out to be highly chemoselective. It required 1.5 equivalents of NBS generating total conversion and an excellent yield of a monobrominated heterocycle after 4 hours of reaction time (Table 4, entry 5). Conventional heating was also studied, but despite increased amounts of NBS and longer reaction times, incomplete conversion and lower yield values were noticed (Table 4, entries 6–8).

Subsequently, two different reaction conditions developed by our group for the Suzuki–Miyaura coupling reaction were tested, both of which proved to be effective (see ESI† for details).<sup>22,28</sup>

The scope of the Suzuki–Miyaura cross-coupling reaction was next examined (Table 5). To our delight, both electron-rich (Table 5, entries 1, 4 and 5) and electron-poor boronic acid partners (Table 5, entries 6–8) lead towards the expected product in good to excellent yields, without any impact of the position of the substituent on the aromatic ring (Table 5, entries 1–3). Additionally, heterocyclic and even styryl boron derivatives were equally compatible with this transformation (Table 5, entries 9–11).

Lastly, the electronic impact of the aryl substituent at the N6 position of the pyrazolo[3,4-*c*]pyrazoles **3b** and **3c** was explored.

<sup>a</sup> 2 h of μWave irradiation necessary for total conversion.

Suitably, independent of the electronic nature of the functional group present on the aromatic moiety, the Suzuki–Miyaura cross-coupling reaction allowed very good to excellent yields (Table 5, entries 12–18).

Compound **4n** was found appropriate for X-ray single crystallography, which confirmed that the bromination and

Fig. 1 ORTEP representation of pyrazolo[3,4-*c*]pyrazole **4n**.

subsequent cross-coupling reaction take place at the C-3 position on the pyrazolo[3,4-*c*]pyrazoles (Fig. 1).<sup>29</sup>

## Conclusions

In summary, the quick access towards variously functionalized pyrazolo[3,4-*c*]pyrazoles is herein described, starting from 5-bromo-1-methyl-1*H*-pyrazole-4-carbaldehyde (**1**). The approach relies on the use of substituted aromatic hydrazines engaged in efficient one-pot sequences. Thus the formed bipyrazoles were subsequently modulated by chemoselective bromination followed by high-yielding Suzuki–Miyaura cross-coupling reactions.

## Experimental section

### Materials and methods

All reagents and organic solvents were purchased from commercial suppliers and were used without further purification. Microwave assisted reactions were carried out in a Biotage Initiator microwave synthesis instrument and temperatures were measured by an IR sensor. Solvents mentioned as dry were purified with a dry station GT S100 immediately prior to use. The reactions were monitored by thin-layer chromatography (TLC) analysis using 0.2 mm pre-coated Kieselgel 60 F254 (Merck) silica gel plates visualized with a Macherey Nagel UV254 lamp. Column chromatography was performed on silica gel 60 (230–400 mesh, 40–63 μm). Solvent ratios for chromatography and are reported as v/v ratios and are indicated for each compound. Melting points (mp [°C]) were taken on samples in open capillary tubes and are uncorrected on an IA9200 Thermo Scientific Electrothermal Melting Point apparatus/instrument. Infrared analyses were determined on a Thermo Scientific ATR Nicolet iS10 and interpreted using OMNIC software. <sup>1</sup>H NMR and <sup>13</sup>C NMR spectra were recorded either on a Bruker ULTRASHIELD® PLUS 400 MHz spectrometer (<sup>13</sup>C, 100 MHz) or on a Bruker AVANCE 250 MHz (<sup>13</sup>C, 62.9 MHz) spectrometer, as solutions in deuterated solvents. Unless otherwise indicated, chemical shifts (δ) are reported in parts per million (ppm) values, and coupling constants (*J*) are reported in Hertz. Peak multiplicities are designated by the following abbreviations: s = singlet; d = doublet; t = triplet; q = quartet; m = multiplet; dd = double doublet, br = broadened. High-resolution mass spectrometry analyses (HRMS) were performed on a Maxis Bruker 4G Spectrometer. X-ray diffraction data were collected on Xcalibur CCD area detector diffractometer equipped with monochromatized Mo-Kα radiation (0.71073 Å) at 296 K. The data collection, unit cell refinement, and data reduction were performed using the CrysAlis Pro, Oxford Diffraction Ltd. software package. Analytical numeric absorption correction using a multifaceted crystal model based on expressions derived was carried. The positions of non-H atoms were determined and refinement by SHELXS-2014 program. Non-hydrogen atoms were first refined isotropically followed by anisotropic refinement by full matrix least-squares calculations based on F2 using SHELXL-2014 program.

### Synthetic procedures

**Synthesis of starting material compound 1.** Copper(II) bromide (6.3 g, 0.0283 mol) and *tert*-butyl nitrite (4.2 mL, 0.0354 mol) were combined in acetonitrile (50 mL). Commercial ethyl 5-amino-1-methyl-1*H*-pyrazole-4-carboxylate (4.0 g, 0.0236 mol) was slowly added portionwise, and the reaction was maintained left at room temperature for 30 minutes. The mixture was cooled to room temperature, poured into aqueous hydrochloric acid (6 N, 160 mL), diluted with dichloromethane (150 mL), and stirred for 10 min. The aqueous layer was extracted with dichloromethane (3 × 100 mL), and the combined organic layers were dried over magnesium sulfate, filtered, and concentrated *in vacuo*. The crude obtained needed no further purification and was engaged in the next step. Yield: 96% (5.33 g). Light yellow solid. Mp: 38–39 °C. <sup>1</sup>H NMR (400 MHz, chloroform-*d*): δ 7.79 (s, 1H), 4.19 (q, *J* = 7.1 Hz, 2H), 3.78 (s, 3H), 1.23 (t, *J* = 7.1 Hz, 3H). <sup>13</sup>C NMR (101 MHz, chloroform-*d*): δ 161.4 (C=O), 141.6 (CH), 117.7 (C), 113.6 (C), 60.1 (CH<sub>2</sub>), 37.8 (N-CH<sub>3</sub>), 14.1 (CH<sub>3</sub>). IR ν (cm<sup>-1</sup>): 2995, 2974, 2931, 2871, 1709, 1528, 1470, 1389, 1214, 1173, 1214, 1173, 1040, 770. HRMS (ESI): (*m/z*) [M + H]<sup>+</sup> calculated for [C<sub>7</sub>H<sub>10</sub><sup>79</sup>BrN<sub>2</sub>O<sub>2</sub>]<sup>+</sup> 232.9920; found 232.9917, calculated for [C<sub>7</sub>H<sub>10</sub><sup>81</sup>BrN<sub>2</sub>O<sub>2</sub>]<sup>+</sup> 234.9900; found 234.9897. A solution of ethyl 5-bromo-1-methyl-1*H*-pyrazole-4-carboxylate (5.33 g, 0.0228 mol) in anhydrous tetrahydrofuran (75 mL) at 0 °C was treated with diisobutylaluminum hydride (1 M solution in tetrahydrofuran, 58 mL, 0.0571 mol), and the mixture was allowed to warm to room temperature and stir for 2 hours. A cold saturated aqueous sodium potassium tartrate solution was added, and stirring was continued for 4 hours. The aqueous layer was extracted with dichloromethane, and the combined organic layers were dried over magnesium sulfate, filtered, and concentrated under reduced pressure. The resulted crude mixture needed no further purification and was engaged in the next step. Yield: 94% (4.14 g). Colorless solid. Mp: 55–56 °C. <sup>1</sup>H NMR (400 MHz, chloroform-*d*): δ 7.48 (s, 1H), 4.46 (s, 2H), 3.82 (s, 3H), 2.53 (s, 1H). <sup>13</sup>C NMR (101 MHz, chloroform-*d*): δ 139.3 (CH), 120.9 (C), 113.7 (C), 55.6 (CH<sub>2</sub>), 37.6 (N-CH<sub>3</sub>). IR ν (cm<sup>-1</sup>): 3255, 2947, 2896, 2848, 2741, 1554, 1413, 1398, 1322, 1189, 1012, 995, 880. HRMS (ESI): (*m/z*) [M + H]<sup>+</sup> calculated for [C<sub>5</sub>H<sub>8</sub><sup>79</sup>BrN<sub>2</sub>O]<sup>+</sup> 190.9815; found 190.9815, calculated for [C<sub>5</sub>H<sub>8</sub><sup>81</sup>BrN<sub>2</sub>O]<sup>+</sup> 192.9794, found 192.9796. A solution of 5-(bromo-1-methyl-1*H*-pyrazol-4-yl) methanol(III) (4.14 g, 0.0216 mol) in dichloromethane (25 mL) was treated with activated manganese(IV) oxide (18.8 g, 0.216 mol) and the mixture was stirred at room temperature for 24 hours. Afterwards, the reaction mixture was filtered on Celite® and the filter pad washed with dichloromethane. The recovered filtrates were then concentrated under reduced pressure to yield the crude compound that required no further purification. Yield: 97% (4.01 g). Light yellow solid. Mp: 75–76 °C. <sup>1</sup>H NMR (400 MHz, chloroform-*d*): δ 9.78 (s, 1H), 7.97 (s, 1H), 3.94 (s, 3H). <sup>13</sup>C NMR (101 MHz, chloroform-*d*): δ 183.4 (C=O), 141.0 (CH), 121.7 (C), 119.7 (C), 37.6 (N-CH<sub>3</sub>). IR ν (cm<sup>-1</sup>): 2953, 2920, 2852, 1655, 1524, 1501, 1454, 1419, 1388, 1368, 1190, 1094, 763. HRMS (ESI): (*m/z*) [M + H]<sup>+</sup> calculated for [C<sub>5</sub>H<sub>6</sub><sup>79</sup>BrN<sub>2</sub>O]<sup>+</sup>

188.9658; found 188.9653, calculated for  $[\text{C}_5\text{H}_6^{81}\text{BrN}_2\text{O}]^+$  190.9638, found 190.9634.

## General procedures

**Synthesis of 1-methyl-6-arylpyrazolo[3,4-*c*]pyrazoles 2a–i.** To a stirred solution of 5-bromo-1-methyl-1*H*-pyrazole-4-carbaldehyde **1** (100 mg, 0.529 mmol, 1.0 eq.) in ethanol (2 mL) a few drops of glacial acetic acid and the desired hydrazine (1.1 eq., 0.58 mmol) were added. If the hydrazine is found under its hydrochloric form salt, a stoichiometric amount of sodium acetate (1.1 eq., 0.58 mmol) is added to the mixture instead of the glacial acetic acid. This mixture was refluxed for 18 h and afterwards concentrated under reduced pressure. The crude was solubilized in DMF (3 mL), transferred to a dry tube and then potassium carbonate (146 mg, 1.06 mmol, 2.0 eq.) and copper iodide (2.5 mg, 0.013 mmol, 2.5 mol%) were added to the mixture. The tube was evacuated, backfilled with dry argon three times and then sealed. The reaction mixture was then heated at 150 °C for 1 hour under microwave irradiation. Solvent removal and purification by silica gel column chromatography using appropriate solvents afforded the expected bicyclic compound.

**Synthesis of 3-bromo-1-methyl-6-arylpyrazolo[3,4-*c*]pyrazoles 3a, 3b and 3c.** To a stirred solution of 1-methyl-6-aryl-pyrazolo[3,4-*c*]pyrazole (**2a**, **2c** or **2e**) (100 mg, 1.0 eq.) in acetonitrile (2 mL) the correspondent amount of NBS is added. Depending on the nature of the substituent, the mixture is left under stirring at reflux or under microwave irradiation (sealed tube) for the given time. The reaction mixture is afterwards extracted with dichloromethane ( $3 \times 10$  mL) and water. The organic layers collected were washed with a saturated solution of  $\text{Na}_2\text{S}_2\text{O}_3$ , dried over  $\text{MgSO}_4$  and evaporated under reduced pressure. The crude product was purified by silica gel column chromatography using appropriate solvents.

**Synthesis of 1-methyl-3-aryl-6-arylpyrazolo[3,4-*c*]pyrazoles 4a–r.** To a stirred solution of 3-bromo-1-methyl-6-aryl-pyrazolo[3,4-*c*]pyrazoles (**3a**, **3b** or **3c**) (100 mg, 1.0 eq.) and corresponding boronic acid (1.5 eq.) in a mixture (3 mL) of dioxane, ethanol and water (3 : 1 : 0.5), a solution of cesium carbonate (1.3 eq.) in 0.5 mL of water was added. The tube was argon flushed three times and then  $\text{Pd}(\text{PPh}_3)_4$  (1.25 mol%) was added. The tube was again argon flushed, sealed and microwave irradiated at 140 °C for 1 h. The reaction mixture was then filtrated on Celite®, rinsed and extracted with EtOAc ( $3 \times 10$  mL). The organic layers collected were washed, dried on  $\text{MgSO}_4$ , filtered and evaporated. The crude obtained was purified by silica gel column chromatography using appropriate solvents, affording the desired compound.

**1-Methyl-6-phenyl-1,6-dihydropyrazolo[3,4-*c*]pyrazole (2a).** Prepared as described in the general procedure A (phenylhydrazine: 63 mg, 57  $\mu\text{L}$ , 0.58 mmol; CuI: 2.5 mg, 0.013 mmol;  $\text{K}_2\text{CO}_3$ : 146 mg, 1.06 mmol). Yield: 76% (80 mg). Orange oil. Column chromatography eluents: PE/EtOAc = 8/2.  $^1\text{H}$  NMR (400 MHz, acetone- $d_6$ ):  $\delta$  7.67 (d,  $J$  = 7.9 Hz, 2H), 7.62 (s, 1H), 7.58 (t,  $J$  = 7.9 Hz, 2H), 7.45 (s, 1H), 7.43 (t,  $J$  = 7.9 Hz, 1H), 3.85 (s, 3H).  $^{13}\text{C}$  NMR (101 MHz, acetone- $d_6$ ):  $\delta$  149.1 (C), 139.8 (C), 130.2 (2

$\times$  CH), 130.0 (CH), 128.0 (CH), 127.6 (CH), 124.1 (2  $\times$  CH), 121.0 (C), 37.7 (N-CH $_3$ ). IR  $\nu$  ( $\text{cm}^{-1}$ ): 3056, 2942, 1682, 1595, 1508, 1457, 1436, 1372, 1189, 1112, 1034, 1004, 990, 969, 844, 759, 715, 696.
