Rational structural modification of the isatin scaffold to develop new and potent antimicrobial agents targeting bacterial peptidoglycan glycosyltransferase†

Yong Wang,‡ Zhiguang Liang,‡ Yuanyuan Zheng, Alan Siu-Lun Leung, Siu-Cheong Yan, Pui-Kin So, Yun-Chung Leung, Wing-Leung Wong and Kwok-Yin Wong 

A series of isatin derivatives bearing three different substituent groups at the N-1, C-3 and C-5 positions of the isatin scaffold were systematically designed and synthesized to study the structure–activity relationship of their inhibition of bacterial peptidoglycan glycosyltransferase (PGT) activity and antimicrobial susceptibility against *S. aureus*, *E. coli* and methicillin-resistant *Staphylococcus aureus* (MRSA (BAA41)) strains. The substituents at these sites are pointing towards three different directions from the isatin scaffold to interact with the amino acid residues in the binding pocket of PGT. Comparative studies of their structure–activity relationship allow us to gain better understanding of the direction of the substituents that contribute critical interactions leading to inhibition activity against the bacterial enzyme. Our results indicate that the modification of these sites is able to maximize the antimicrobial potency and inhibitory action against the bacterial enzyme. Two compounds show good antimicrobial potency (MIC = 3 $\mu\text{g mL}^{-1}$ against *S. aureus* and MRSA; 12–24 $\mu\text{g mL}^{-1}$ against *E. coli*). Results of the inhibition study against the bacterial enzyme (*E. coli* PBP 1b) reveal that some compounds are able to achieve excellent *in vitro* inhibitions of bacterial enzymatic activity (up to 100%). The best half maximal inhibitory concentration (IC₅₀) observed among the new compounds is 8.9 μM .

1. Introduction

Since the first discovery of the penicillin antibiotic in 1928, it has started the golden era of antibiotic discovery and development based on natural products.¹ Over the past several decades, β -lactam antibiotics, such as penicillins, cephalosporins, monobactams, and carbacephems have been the most important and widely used clinical drugs to treat worldwide bacterial infections.² The bacterial cell walls, of either Gram-positive or Gram-negative bacteria, play important roles to support bacteria to survive. Bacterial cell walls are constructed from peptidoglycans, which are cross-linked biopolymers.³ Most β -lactam antibiotics kill bacteria through the effective inhibition of the formation of peptidoglycan cross-links.⁴ Unfortunately, the overuse and sometimes abuse in various fields (*e.g.* ranging from clinical treatment to animal farming), bacteria evolve continuously into more powerful drug-resistant strains, and the

ever evolution of drug resistance in many human pathogens has caused the emergence of worldwide ‘superbug crisis’, which seriously threaten global human health.^{5,6}

There are two generally accepted approaches to resolving the crisis of antimicrobial resistance: (i) development of synergistic combined therapies *via* the development of broad-spectrum inhibitors to restore the antibacterial activity of conventional antibiotics,^{7,8} and (ii) discovery of new antibiotics with a novel mode of antibacterial mechanism different from that of β -lactam antibiotics;^{9,10} to this end, scientists have to target at a new and highly conserved and critical bacterial enzyme for drug discovery. Over the last century, inhibition of bacterial cell wall syntheses is the most effective mean to inhibit bacterial growths by inducing their cell lysis.¹¹ It is well known that both peptidoglycan glycosyltransferase (PGT) and transpeptidase (TP) activities of penicillin-binding proteins (PBPs) are essential for synthesizing bacterial cell walls. Although antibiotic resistance has emerged on the TP/PBP module, PGT is definitely another critical target for new drug discovery.^{12–16} However, compared to TP, the understanding and research findings about the structural and functional information of PGT are very limited, which largely restricts the rational design of new PGT inhibitors with high potency. The discovery of new inhibitors against PGT is therefore still very challenging.

‡ The authors contributed equally to this work.

Over the past twenty years, only a few potent inhibitors against PGT have been reported. Examples include disaccharide-modified molecules,^{17–20} monosaccharide-modified scaffolds,¹³ phosphoglycolipid AC326- α ,²¹ coeophomones A and B,²² structurally modified moenomycin A derivative,^{23–26} modified peptidoglycan analogues,²⁷ tryptamine-based compounds,²⁸ and small molecules identified *via* high-throughput screening.^{29–33} Most inhibitors discovered so far are based on high-throughput screening, while inhibitors against the lipid-II binding site of PGT through molecular designs remain rare.³⁴ Nonetheless, rational design of small molecule-based inhibitors with diverse structural scaffolds provides a good approach to understanding structure–activity relationship in depth. Moreover, this method enriches the molecular diversity for further improving the potency of PGT inhibitors. Our previous study *via* high-throughput screening has successfully identified a natural heterocyclic compound, isatin (1*H* indole-2,3-dione), which is found to be a potential PGT inhibitor after a simple modification on its N-1 and C-3 positions.^{32,35} The 2-site structural modifications, however, have not fully utilized the potential pharmacological properties of isatin moiety because its molecular scaffold allows multi-site three-directional structure modifications to create additional chemical features to fit for a specific purpose. Recent literature have shown that the diverse pharmacological properties of isatin-modified compounds have been identified in many other research areas,^{36,37} such as anti-cancer,³⁸ anti-tubercular,³⁹ antimalarial,⁴⁰ anti-HIV⁴¹ and anti-bacterial^{42,43} treatments with good potency. In the present study, bacterial PGT inhibitors with three-directional structural modifications based on the isatin scaffold at the N-1, C-3 and C-5 positions (Scheme 1) was synthesized through structure-based design and then studied to gain better understanding of their structure–activity relationships towards the lipid-II binding pocket of bacterial peptidoglycan glycosyltransferase. The antimicrobial potency of the new inhibitors against Gram-positive (*S. aureus* (29213)), Gram-negative (*E. coli* (25922)) strains, and methicillin-resistant *Staphylococcus aureus* (MRSA (BAA41)) were also investigated.

2. Results and discussion

Twelve isatin derivatives bearing three different substituent groups at the N-1, C-3 and C-5 positions of isatin scaffold (Scheme 1) were synthesized through two different synthetic approaches (Fig. S1†). The substituents at these positions of isatin are pointing to three different directions (Scheme 1), which allow maximizing the molecular interactions with the PGT binding pocket. More importantly, studying the activities of these compounds enable us to find out the direction of the substituent that provides critical interactions. The N-1 site was substituted with a flexible and lipophilic chain of various lengths (the carbon number of the aliphatic chain ranges from 4 to 14) as this substituent has been proposed to point towards the bacterial cell membrane region, where non-polar interactions are favorable. For the C-3 site, the functional ketone group of isatin was replaced with a polar guanidine group, which bears a positive charge (protonated form) and can therefore

allow effective polar interactions with polar amino acid residues in the PGT binding pocket through hydrogen bonding and/or charge interactions. The PGT-inhibitory activity of the substituent effect at the C-5 site of isatin has not been investigated so far. This prompted us to synthesize four different substituents at this site so as to conduct comparative structure–activity relationship studies on the inhibitory activity against *E. coli* PBP 1b enzyme and the MIC effects against the Gram-positive and negative strains.

The antimicrobial susceptibility tests of the new 3-site modified isatin derivatives were conducted with three strains: *S. aureus*, MRSA, and *E. coli*. The MIC results are summarized in Table 1. Compound 1, with no substituent at its C-5 site, show a MIC of 6 $\mu\text{g mL}^{-1}$ (against *S. aureus*), 6 $\mu\text{g mL}^{-1}$ (against MRSA), and 12 $\mu\text{g mL}^{-1}$ (against *E. coli*), respectively. When a methyl group ($-\text{CH}_3$) was introduced at the C-5 site (compound 2), its antimicrobial potency appears to increase against the strains (3 $\mu\text{g mL}^{-1}$ for *S. aureus* and MRSA; 12 $\mu\text{g mL}^{-1}$ for *E. coli*). These results indicate that the C-5 site of isatin scaffold is important for structural modifications. We therefore further modified the structure with an electron-donating methoxy group ($-\text{OCH}_3$) and electron withdrawing groups ($-\text{F}$ and $-\text{NO}_2$) for comparison purposes. However, regarding the MIC values, a gradual reduction in the antimicrobial potency with these substituents appears (Table 1). Moreover, a MIC trend on the substituent groups at the C-5 site decreases in this order: $-\text{CH}_3 > -\text{H} \approx -\text{OCH}_3 > -\text{F} > -\text{NO}_2$ (Table 1). It seems that the nitro-group shows a significant decline in the antimicrobial potency ($\text{MIC} > 192 \mu\text{g mL}^{-1}$), which is probably due to the strong electron-withdrawing character of $-\text{NO}_2$ group that may reduce its ability to develop hydrogen bonding interactions in the PGT active site.⁴⁴ To further verify these compounds can bind to PBP 1b enzyme and interfere with the lipid II polymerization, *in vitro* HPLC analyses using fluorescent dansyl-lipid II as the substrate^{45,46} were conducted against *E. coli* PBP 1b. The result indicates that compound 2 has the best inhibitory effect (the residual activity of the enzyme = 12%), while compound 5 with a nitro-substituent at the C-5 site shows no significant inhibitory effect. In this regard, the HPLC data are consistent with their MIC values. The results implies that the antimicrobial activity of the compounds is probably attributed to the inhibition of PBP 1b enzyme activity.

We further modified the structure of compound 2 at the C-3 and N-1 sites for structure–activity comparison. At the N-1 site, a series of *n*-alkyl chains with various carbon atoms was synthesized, and the compounds (6–11) were also examined for their MIC values against three strains. Compound 6 has a short *n*-alkyl chain (butyl group) substituted at the N-1 site shows much poorer antimicrobial potency than compound 2 that bears a butylphenyl group at the same site. Interestingly, when the length of the *n*-alkyl chain increases from butyl to decyl (compound 7, 8, and 9), the antimicrobial activities of the compounds are improved gradually. This indicates that the N-1 site is sensitive to the hydrophobicity of the substituent, which probably interacts with the lipophilic region of the bacterial membrane. It seems that an aliphatic chain with 10 carbon atoms has optimal antimicrobial activity (MIC of compound 9 =

Scheme 1 Three-site modified isatin derivatives for new antimicrobial studies on bacterial peptidoglycan glycosyltransferase (PGT).

3 $\mu\text{g mL}^{-1}$ against *S. aureus* and MRSA). Further increasing the chain length results in a significant reduction in antimicrobial potency; for example, compound **11** gave MIC >192 against *S. aureus*, MRSA, and *E. coli*. In general, the substitution at the N-1 site with a long aliphatic chain (8–11 carbon atoms) can enhance the inhibitory activity against PBP 1b but is unable to improve further the antibacterial potency, probably due to unfavorable factors, such as poor solubility and diffusion problem caused by the highly hydrophobic and bulky

molecules. Based on the results of the compound series, compound **2** and **9** are the most potent antibacterial agents and their K_i values against *E. coli* PBP 1b are 3.2 and 2.4 μM , respectively (Fig. 1).

In order to demonstrate the importance of the guanidine moiety at the C-3 site of isatin, we replaced it with thiosemicarbazide (compound **12**). Results of the enzyme inhibition assay and antibacterial ability test, the *in vitro* inhibitory enzymatic activity of compound **12** is significantly reduced as

^a *E. coli* PBP 1b inhibitor.¹⁶

Fig. 1 Half maximal inhibitory concentration of compound 2 and 9 against *E. coli* PBP 1b.

compared to compound 9. Inhibition assays with compound 12 at 50 μM , *E. coli* PBP 1b retains 60% activity while compound 9 achieves 100% inhibition (Table 1). Moreover, compound 12 reveals very weak antibacterial activity, as indicated by its relatively high MIC value $> 192 \mu g mL^{-1}$ against the bacterial strains examined. These results suggest that the C-3 site requires a highly polar group (e.g. guanidine) capable of providing strong hydrogen bonding and/or charge interactions with the polar residues in the PGT binding pocket.

The cytotoxicity of compound 2, 9, and 12 were evaluated with MTT assays using a normal human cell line BJ (ATCC CRL-2522) for 24 h treatment. The results are shown in Fig. 2. Compound 2 and 9 show comparable cell proliferation profiles. At the concentration of 2 $\mu g mL^{-1}$ or below, the cell viability is higher than 80%, indicating that both compounds are not toxic to the cells at these concentrations. The IC_{50} estimated for compound 2 and 9 against BJ cells are 6.6 $\mu g mL^{-1}$ and 5.4 $\mu g mL^{-1}$ (analyzed with Prism 6.0), which are higher than the MIC value (3 $\mu g mL^{-1}$) of compound 2 and 9 against *S. aureus* and MRSA strains (Table 1). Moreover, it is noteworthy that compound 12 has a relatively low cytotoxicity, as revealed by about 80% cell viability after incubation at much higher concentration (18 $\mu g mL^{-1}$). The results suggest that the cytotoxicity of the compounds is likely to be attributed from the guanidine moiety at the C-3 site of the isatin scaffold.

Fig. 2 Cytotoxicity evaluation for compound 2, 9, and 12 in cell proliferation of a normal human cell line BJ (ATCC CRL-2522) in 24 h treatment. Data are presented in mean \pm SD of three independence experiments, each performed in triplicate.

Molecular docking study was then performed to understand the possible binding modes and locations of the molecules in the PGT binding pocket. The docking models between the selected compounds (compound 2, 6, 9 and 12) and *S. aureus* monofunctional glycosyltransferase (Mtg) were generated by AutoDock Vina. The most favorable interaction modes are shown in Fig. 3 and S5.† All these compounds are located at the same region, which is different from the natural macromolecular inhibitor moenomycin A. It is, however, interesting to note that both the non-polar aliphatic chains substituted at the N-1 site of the compounds (except compound 6 with a short butyl chain) and the long C_{25} isoprene tail of moenomycin A are pointing to the same direction to interact with the trans-membrane region of the enzyme. This possibly causes compound 6 has much lower inhibitory enzymatic activity than compound 9. In addition, the decyl group of compound 9 also exhibits hydrophobic interactions with Phe110, Leu112, Phe157, and Leu158. The methyl group substituted at the C-5 site of the molecule shows a close contact with Thr115. Furthermore, its guanidine group at the C-3 site forms six hydrogen bonds with Gln100, Gln129, Gly130, Thr133, and Gln136, thus giving strong binding interactions. When the guanidine group is replaced by thiosemicarbazide, the binding between compound 12 and PGT is weakened due to loss of two hydrogen bonds. These docking results are consistent with their relatively low MIC values and the *in vitro* inhibition activities against the *E. coli* PBP 1b enzyme.

3. Experimental

3.1. General synthetic procedures of *N*-4-butylphenyl-5-substituent-isatin analogues (compound 1–5)

Compound 1 was synthesized and purified by following the reported procedures.³⁵ For the synthesis of compound 2–5, to the mixture of 1 mM 5-substituent isatin, 1 mM 4-butylphenyl boronic acid, 3 mM triethylamine in 20 mL CH_2Cl_2 and activated 4 Å molecular sieve, 1 mM copper(II) acetate were added, and the mixture was kept stirring until reaction was completed. The solid was then removed and washed by CH_2Cl_2 (20 mL \times 3). The combined organic layer was dried with anhydrous Na_2SO_4 . After removal of the solvent, the product was purified by silica gel chromatography with ethyl acetate/petroleum ether (vol.

Fig. 3 (A) Docking models between inhibitors (compound 2, 6, 9 and 12) and *S. aureus* monofunctional glycosyltransferase (protein ID: 3HZS):⁴⁷ moenomycin A (red), compound 2 (blue), 6 (yellow), 9 (purple), and 12 (cyan). (B) The interactions between 9 and *S. aureus* monofunctional glycosyltransferase were generated from AutoDock tools.^{48,49}

ratio = 1 : 4) as the eluent. The final product was obtained by refluxing the mixture of 0.5 mM *N*-4-butyphenyl-5-substituent-isatin and 0.6 mM aminoguanidine hydrochloride in CH_3COOH (10 mL) for 2 h. Yellow solid was obtained by introducing diethyl ether into the mixture. Finally, the product was purified by silica gel chromatography with methanol/dichloromethane (vol. ratio = 1 : 10) as the eluent.

3.2. General synthetic procedures of *N*-aliphatic chain-5-methyl-isatin analogues (compound 6–12)

To the mixture of 1 mM 5-methylisatin, 1 mM 1-bromo aliphatic alkane in 10 mL of DMF and 3 mM potassium carbonate were added, and the mixture was stirred at 80 °C for 5 h until starting compounds were consumed. The mixture was then poured into cold water and extracted by ethyl acetate (20 mL \times 3) and washed by DI water (20 mL \times 3), followed by drying with anhydrous Na_2SO_4 . After removing the solvent, the product was purified by silica gel chromatography with ethyl acetate/petroleum ether (vol. ratio = 1 : 5) as the eluent. The final product was obtained as previously described.

3.3. Characterization of compounds

Compound 2. Yield 75%. ^1H NMR (400 MHz, CD_3OD) δ : 1.00 (t, J = 7.4 Hz, 3H, CH_2CH_3), 1.39–1.48 (m, 2H, CH_2CH_3), 1.65–1.73 (m, 2H, CH_2CH_2), 2.40 (s, 3H, Ar- CH_3), 2.74 (t, 2H, J = 7.7 Hz, N- CH_2), 6.79 (d, J = 8.1 Hz, 1H, Ar-H), 7.26 (d, J = 8.1 Hz, 1H, Ar-H), 7.37–7.44 (m, 4H, Ar-H), 7.69 (s, 1H, Ar-H). ^{13}C NMR (125 MHz, CD_3OD) δ : 12.92, 19.63, 22.01, 33.51, 34.97, 110.08, 119.06, 121.98, 126.04, 129.45, 130.66, 132.64, 133.70, 137.53, 142.61, 143.77, 156.43, 160.63. HRMS calculated for $\text{C}_{20}\text{H}_{24}\text{N}_5\text{O}$: m/z : 350.1975 $[\text{M} + \text{H}]^+$, found 350.1981. HPLC analysis (mobile phase: 20% water in methanol): retention time = 14.5 min; purity > 95%.

Compound 3. Yield 65%. ^1H NMR (400 MHz, CD_3OD) δ : 1.00 (t, J = 7.4 Hz, 3H, CH_2CH_3), 1.39–1.48 (m, 2H, CH_2CH_3), 1.65–

1.73 (m, 2H, CH_2CH_2), 2.74 (t, 2H, J = 7.7 Hz, Ar- CH_2), 3.86 (s, 3H, OCH_3), 6.83 (d, J = 8.7 Hz, 1H, Ar-H), 7.01 (d, J = 8.7 Hz, 1H, Ar-H), 7.38–7.44 (m, 4H, Ar-H), 7.48 (s, 1H, Ar-H). ^{13}C NMR (125 MHz, CD_3OD) δ : 12.93, 22.02, 33.51, 34.97, 55.05, 106.83, 111.13, 117.89, 119.95, 125.93, 129.44, 130.74, 137.49, 138.35, 143.67, 156.52, 157.00, 160.49. HRMS calculated for $\text{C}_{20}\text{H}_{24}\text{N}_5\text{O}_2$: m/z : 366.1925 $[\text{M} + \text{H}]^+$, found 366.1924.

Compound 4. Yield 63%. ^1H NMR (400 MHz, CD_3OD) δ : 0.99 (t, J = 7.3 Hz, 3H, CH_2CH_3), 1.38–1.48 (m, 2H, CH_2CH_3), 1.65–1.72 (m, 2H, CH_2CH_2), 2.74 (t, 2H, J = 7.7 Hz, Ar- CH_2), 6.86 (d, J = 8.7 Hz, 1H, Ar-H), 7.16 (t, J = 8.9 Hz, 1H, Ar-H), 7.37–7.44 (m, 4H, Ar-H), 7.61 (d, J = 7.8 Hz, 1H, Ar-H). ^{13}C NMR (125 MHz, CD_3OD) δ : 12.87, 21.96, 33.41, 34.91, 108.24, 108.50, 111.30, 117.72, 117.96, 126.13, 129.43, 130.49, 136.20, 140.45, 143.78, 158.46, 160.85. Compound 8. Yield 88%. ¹H NMR (400 MHz, CD₃OD) δ : 0.90 (t, *J* = 6.7 Hz, 3H, CH₂CH₃), 1.30–1.37 (m, 10H, CH₂), 1.72 (t, *J* = 6.9 Hz, 2H, CH₂CH₃), 2.38 (s, 3H, Ar-CH₃), 3.78 (t, 2H, *J* = 7.1 Hz, N-CH₂), 6.99 (d, *J* = 8.1 Hz, 1H, Ar-H), 7.31 (m, *J* = 8.1 Hz, 1H, Ar-H), 7.60 (s, 1H, Ar-H). ¹³C NMR (125 MHz, CD₃OD). δ : 13.07, 19.63, 22.34, 26.53, 27.10, 28.91, 28.95, 31.58, 39.39, 109.60, 118.92, 121.99, 132.77, 133.15, 137.77, 141.71, 156.28, 161.13. HRMS calculated for C₁₈H₂₈N₅O: *m/z*: 330.2288 [*M* + H]⁺, found 330.2300.

Compound 9. Yield 81%. ¹H NMR (400 MHz, CD₃OD) δ : 0.91 (t, *J* = 7.0 Hz, 3H, CH₂CH₃), 1.29–1.38 (m, 14H, CH₂), 1.73 (t, *J* = 6.7 Hz, 2H, CH₂), 2.39 (s, 3H, Ar-CH₃), 3.79 (t, 2H, *J* = 7.1 Hz, N-CH₂), 7.00 (d, *J* = 8.0 Hz, 1H, Ar-H), 7.32 (d, *J* = 8.0 Hz, 1H, Ar-H), 7.61 (s, 1H, Ar-H). ¹³C NMR (125 MHz, CD₃OD). δ : 13.10, 19.63, 22.38, 26.50, 27.08, 28.91, 29.08, 29.24, 29.26, 31.71, 39.39, 109.60, 118.94, 121.98, 132.76, 133.15, 137.76, 141.71, 156.31, 161.14. HRMS calculated for C₂₀H₃₂N₅O: *m/z*: 358.2601 [*M* + H]⁺, found 358.2616. HPLC analysis [mobile phase 10% (v/v) water in methanol]: retention time = 9 min; purity > 90%.

Compound 10. Yield 80%. ¹H NMR (400 MHz, CD₃OD) δ : 0.91 (t, *J* = 7.0 Hz, 3H, CH₂CH₃), 1.28–1.37 (m, 16H, CH₂), 1.72 (t, *J* = 6.6 Hz, 2H, CH₂), 2.38 (s, 3H, Ar-CH₃), 3.78 (t, 2H, *J* = 7.1 Hz, N-CH₂), 6.99 (d, *J* = 8.0 Hz, 1H, Ar-H), 7.31 (d, *J* = 8.0 Hz, 1H, Ar-H), 7.60 (s, 1H, Ar-H). ¹³C NMR (125 MHz, CD₃OD). δ : 13.11, 19.65, 22.39, 26.50, 27.09, 28.92, 29.12, 29.24, 29.30, 29.36, 31.71, 39.38, 109.56, 119.03, 121.93, 132.66, 133.10, 137.64, 141.63, 156.50, 161.08. HRMS calculated for C₂₀H₃₂N₅O: *m/z*: 372.2758 [*M* + H]⁺, found 372.2775.

Compound 11. Yield 83%. ¹H NMR (400 MHz, CD₃OD) δ : 0.91 (t, *J* = 7.0 Hz, 3H, CH₂CH₃), 1.29–1.38 (m, 22H, CH₂), 1.73 (t, *J* = 6.9 Hz, 2H, CH₂), 2.38 (s, 3H, Ar-CH₃), 3.79 (t, 2H, *J* = 7.1 Hz, N-CH₂), 7.00 (d, *J* = 8.0 Hz, 1H, Ar-H), 7.31 (d, *J* = 8.0 Hz, 1H, Ar-H), 7.60 (s, 1H, Ar-H). ¹³C NMR (125 MHz, CD₃OD). δ : 13.10, 19.63, 22.40, 26.50, 27.09, 28.91, 29.13, 29.23, 29.29, 29.38, 29.42, 31.74, 39.39, 109.60, 118.96, 121.97, 132.76, 133.13, 137.78, 141.72, 156.34, 161.14. HRMS calculated for C₂₄H₄₀N₅O: *m/z*: 414.3227 [*M* + H]⁺, found 414.3245.

Compound 12. Yield 75%. ¹H NMR (400 MHz, CD₃OD) δ : 0.91 (t, *J* = 7.0 Hz, 3H, CH₂CH₃), 1.29–1.37 (m, 14H, CH₂), 1.72 (t, *J* = 7.0 Hz, 2H, CH₂), 2.38 (s, 3H, Ar-CH₃), 3.78 (t, 2H, *J* = 7.1 Hz, N-CH₂), 6.96 (d, *J* = 8.0 Hz, 1H, Ar-H), 7.26 (d, *J* = 7.6 Hz, 1H, Ar-H), 7.55 (s, 1H, Ar-H). ¹³C NMR (125 MHz, CD₃OD). δ : 13.10, 19.65, 22.38, 26.49, 27.13, 28.90, 29.06, 29.22, 29.24, 31.71, 39.25, 109.34, 119.60, 121.22, 131.69, 132.37, 132.80, 141.20, 161.28, 180.00. HRMS calculated for C₂₀H₃₁N₄OSNa: *m/z*: 397.2038 [*M* + Na]⁺, found 397.2041.

3.4. Antimicrobial susceptibility tests

The MIC values of the compounds (compound 1–12) was measured by antimicrobial susceptibility tests using the broth microdilution procedure according to the Clinical and

Laboratory Standards Institute (CLSI) guidelines. Cation-adjusted Mueller Hinton broth (CA-MHB) for *S. aureus* strain ATCC 29213 and Mueller Hinton broth (MHB) for antibiotic-susceptible strains *B. subtilis* strain 168 and *E. coli* strain ATCC 25922 were used in the assays. Cells in exponential phase of growth were diluted to approximately 5×10^5 cfu mL⁻¹. A stock solution of each compound were prepared in DMSO. Serial dilutions of each compound in DMSO and bacteria were mixed in a 96-well microplate. The final percentage of DMSO in the assay was 1% (v/v). Control experiments were performed with 1% (v/v) DMSO instead of the solution of the compounds. After incubation at 37 °C for 18 h, the OD₆₀₀ value of the cells was measured on a microplate reader (Bio-Rad laboratory Ltd., UK), and the percentage of bacterial cell inhibition with respect to the controls calculated. The MIC value was defined as the lowest compound concentration at which the growth of bacteria was inhibited by $\geq 90\%$. Three independent assays were performed for each test.

3.5. Lipid II-based *in vitro* transglycosylation assay

E. coli PBP 1b (13.2 nM) and the compounds (1–12) were pre-incubated at 30 °C for 5 min in reaction buffer (50 mM HEPES, pH 7.5 containing 200 mM NaCl and 10 mM CaCl₂) with additional 0.08% (v/v) decyl PEG, 10% (v/v) DMSO, 15% (v/v) CH₃OH and 2 U μ L⁻¹ muramidase. Dansyl-lipid II (working concentration = 5 μ M) was then added into the reaction mixture, mixed well and incubated at 30 °C for another 5 min. MoeA (working concentration = 1 μ M) was added and incubated for another 10 min to quench the reaction and completely cleave the produced glycan chain. The mixtures were stored at –80 °C before HPLC analysis. A 10 μ L portion of samples was injected into an Agilent 1200 series equipped with a Supelco SAX1 anion-exchange column and eluted using a gradient elution method [NH₄OAc (0.5 M in methanol) to MeOH (10% isopropanol) from 4% : 96% to 100% : 0%] in 30 min. All compounds were measured in duplicate, the half maximal inhibitory concentrations (IC₅₀) of selected compounds were calculated by GraphPad Prism 8 with the model: $Y = 1/(1 + 10^{(\log IC_{50} - X) \times h})$ (*Y*, normalized response; *X*, log [inhibitor]; *h*, hillslope). Inhibition constants (*K_i*) were calculated according to the formula $IC_{50} = K_i(1 + [S]/K_m)$, *K_m* = 1.8 μ M) reported in literature.^{50,51}

3.6. Cell proliferation assays

The normal human cell line BJ cells (ATCC CRL-2522) were cultured in a medium according to ATCC recommendations. All culture cell lines were maintained in a humidified culture chamber at 37 °C and 5% CO₂. The cell lines were first seeded in a 96-well plate at a density of 5×10^3 cells per well. After incubation for one day, the cells were treated with the medium containing different concentrations of compounds (2, 9, 12). After 24 h of drug treatment, the culture medium was replaced with MTT solution (1 mg mL⁻¹) (Invitrogen) and incubated at 37 °C for four hours. After incubation, the MTT solution was replaced with dimethyl sulfoxide (DMSO), and the absorbance at 570 nm measured with 650 nm as the reference. The cell

viability was determined by dividing the absorbance of treated cells by the average absorbance of untreated cells. The IC₅₀ values of the compounds (**2**, **9**, and **12**) on the normal human cell line BJ cells (at 95% confidence level) were analyzed by the software Prism 6.0. Three independent sets of experiments ($n = 3$) were performed for each cell line.

3.7. Molecular modeling

Molecular models between the *S. aureus* monofunctional GT (protein PDB code: 3HZS) and isatin analogues was performed using AutoDock Vina.⁵² All the 3D coordinates of isatin analogues were generated by ChemDraw Ultra 8.0 and energy minimized by Avogadro with Merck Molecular Force Field 94 (MMFF94).⁵³ The protein PDB and ligands MOL2 files were handled by reported procedures.⁵⁴ The docking box contained the whole GT pocket.

4. Conclusions

In conclusion, a series of new isatin derivatives was synthesized through three-direction modifications on the N-1, C-3 and C-5 positions of the isatin scaffold. The structure–activity relationship was investigated in antimicrobial susceptibility tests against Gram-positive (*S. aureus* (29213)), Gram-negative (*E. coli* (25922)) strains, and methicillin-resistant *Staphylococcus aureus* (MRSA (BAA41)) as well as the *in vitro* enzymatic inhibition assays with *E. coli* PBP 1b. It was found that the modifications on these 3 sites are able to maximize the antimicrobial potency and enzyme inhibitory activities. Two compounds (**2** and **9**) were identified as the potential candidates for new antimicrobial agent development against bacterial peptidoglycan glycosyltransferase. In addition, our cytotoxicity evaluation studies have shown that the toxicity of the compounds (**2**, **9**, **12**) may be primarily attributed to the guanidine substituent group at the C-3 site of isatin scaffold, which is also a crucial moiety of the molecule to achieve good antimicrobial potency against the three bacterial stains.

Conflicts of interest

There are no conflicts to declare.
