Aminations and arylations by direct C–O activation for the design of 7,8-dihydro-6*H*-5,8-ethanopyrido [3,2-*d*]pyrimidines†

The design of some novel disubstituted 7,8-dihydro-6*H*-5,8-ethanopyrido[3,2-*d*]pyrimidine derivatives is reported. The series was developed from quinuclidinone, which afforded versatile platforms bearing one lactam function in position C-2 that were then used to create C–N or C–C bonds for *S_NAr* or palladium-catalyzed cross-coupling reactions by *in situ* C–O activation. The reaction conditions were optimized under microwave irradiation, and a wide range of amines or boronic acids were used to determine the scope and limitations of each method. To complete this study, the X-ray crystallographic data of 7,8-dihydro-6*H*-5,8-ethanopyrido[3,2-*d*]pyrimidine derivative **49** were used to formally establish the structures of the products.

Introduction

Exploring chemical space is a major challenge to discover new biologically active small molecules.^{1–3} This strategy has long been applied in heterocyclic chemistry, in particular through the design and the functionalization of fused polynitrogenated derivatives, which contain hetero-aromatic and aliphatic moieties.^{4–8} The resulting original structures increase the molecular diversity and find applications in reagents, 3D fine chemical or novel pharmaceutical specialities.^{9–11} Among those reported in the aliphatic series, quinuclidine holds an important place due to its presence in a number of natural products, such as *Cinchona officinalis* alkaloids or FDA-approved drugs (Fig. 1).^{12–17} Moreover, this skeleton has also been used as a catalyst for the development of asymmetric aldolisation, Baylis–Hillman or Diels–Alder reactions.^{18–23}

The fusion of quinuclidine to aromatic and nitrogen-containing heterocycle moieties has seldom been reported. Only a few references describe the synthesis and the reactivity of this skeleton with a pyridine group as an example.^{24–26} This may be due to the strong Brønsted and Lewis basic character of the nitrogen atom, which is likely to inhibit a large panel of

reactions.²⁷ For our own part, our group has developed efficient methodologies to functionalize and obtain biologically active molecules in the pyrimidine series such as pyrido[3-2,*d*]pyrimidines, pyrido[1',2':1,5]pyrazolo[3,4-*d*]pyrimidines or pyrido[1',2':1,5]pyrazolo[4,3-*d*]pyrimidine.^{28–31} To escape from flatland and evaluate the replicability of our know-how in this poorly explored area, we propose in this paper the access to a 4-aryl-7,8-dihydro-1*H*-5,8-ethanopyrido[3,2-*d*]pyrimidin-2(6*H*)-one platform and its further substitution at the C-2 position.³² This fused arylated skeleton **A** resulting from the fusion of a quinuclidine and a pyrimidine (quinuclidino-pyrimidinone) was functionalized by aminations or the Suzuki–Miyaura cross-coupling reaction using *in situ* C–O activation, an innovative and direct method that is particularly powerful to modulate heteroaromatic structures (Fig. 2).

Results and discussion

To perform the required C-2 amination or Suzuki–Miyaura cross-coupling reactions, some ethanopyrido[3,2-*d*]pyrimidinones of type **A** were prepared in two steps. First, 4-aryl-

7,8-dihydro-1*H*-5,8-ethanopyrido[3,2-*d*]pyrimidin-2(6*H*)one **2–4** were obtained in satisfactory yields after aldol condensation between the commercially available 3-quinuclidinone hydrochloride **1** with three benzaldehydes in presence of sodium hydroxide. Next, a solvent-free condensation with urea was performed to generate bicyclic tetrahydropyrimidines **5–7**.³³ Finally, an oxidative hetero aromatization was carried out using manganese dioxide³⁴ in acetone under microwave irradiation to access the desired platforms **8–10** in very good to excellent yields (Scheme 1).

To take advantage of the lactam, we began our methodological study by a one-pot amination at the C-2 position using C–O direct activation involving PyBrOP and Et₃N.^{35–37} In this tandem reaction, the first *in situ* step generated the *O*-phosphonium leaving group, which was then displaced with the adequate nucleophile. In a first attempt, the reactivity was examined by treating 4-phenyl-pyrido[3,2-*d*]pyrimidinone **8** with *n*-propylamine and several reaction parameters (temperature, duration) were screened to reach an acceptable level of reaction efficiency (Table 1).^{38,39}

The first step was also performed with **8** in the presence of PyBrOP at a temperature of 80 °C and after 2 h the primary

amine (2.2 eq.) was added. After 3 additional hours, only a small proportion of the intermediate had been consumed and the desired product **11** was isolated in low yield whereas a large amount of starting material **8** was recovered. Increasing the temperature to 100 °C slightly enhanced the yield to 32%. A time reaction screening for each step (*t*₁ and *t*₂) led to interesting results. A full conversion of **8** to *O*-phosphonium was reached after 3 h at 100 °C. The nucleophilic attack of the amine on the activated heterocycle was the rate-limiting step. The second step was achieved during 17 h at 100 °C and led to the desired compound **11** in 72% of yield.

In order to explore the scope and limitations of this tandem sequence, we then condensed previously synthesized ethanopyrido[3,2-*d*]pyrimidinones **A** with various amines (Table 2). With 1-pentylamine and **8**, the yield decreased slightly (entry 2 *versus* 1). The same behaviour was observed when benzyl amines were used (entries 8–10). An attempted strengthening of nucleophilicity with secondary cyclic amines such as piperidine, morpholine or thiomorpholine increased the reactivity up to 82% (entries 3–7). Moreover, when piperidine was used as a secondary amine with ethanopyrido[3,2-*d*]pyrimidinones **9** and **10**, the two S_NAr reactions were efficiently achieved and compounds **23** and **24** were isolated in 86% and 79% of yield, respectively (entries 15–16).

During this investigation, we encountered two limitations when anilines or lactams, which are very weakly nucleophilic species, were used: the final compounds **21** and **22** (entries 12, 13) were never observed. To access these derivatives, it became necessary to develop a one-pot sequence involving *in situ* CO-activation followed by a Pd-catalyzed C–N bond forming sequence, an original alternative to the previously unsuccessful S_NAr method.

First, we used δ -valerolactam as amide to prevent any S_NAr competition, Pd₂dba₃ as the palladium source in the presence of Xantphos as bidentate ligand, K₂CO₃ as base, and dioxane as solvent. With these conditions, the desired product **22** was isolated in low yield (19%, Table 3, entry 1) despite the total consumption of the starting material, indicating the low reactivity of the *O*-phosphonium intermediate. When the palladium catalyst was replaced by Pd(OAc)₂, the same behaviour was observed and the desired compound **22** was obtained in a similar 21% yield. By increasing the catalytic charge to 10 mol% the *O*-phosphonium species was consumed, affording **22** in 40% of yield accompanied with degradation. A fine adjustment of the temperature (to 150 °C) drastically decreased the yield (entry 4) and the replacement of Xantphos with well-known Buchwald ligands such as CyJohnPhos or Ruphos totally inhibited the reactivity. Changing the nature of the base indicated that the use of Na₂CO₃ and Cs₂CO₃ was not tolerated and showed the highest reaction sensitivity (entries 7, 8).

Next, the scope and generality of the Pd-coupling step were examined. The 2-pyrrolidinone reaction gave the desired product **25** with the same reactivity (Table 4, entry 2), whereas using aniline afforded product **26** in a good isolated yield of 56% (Table 4, entry 4). The reactions proceeded with the same efficiency regardless of the nature of the aniline used (*i.e.*, with electron-withdrawing or electron-donating substituents) and the compound **21** was finally synthesized with these conditions (entry 1). Steric hindrance symbolized by the presence of a methyl group on the aniline in *ortho* vs. *meta* or *para* position (entries 1, 6–7) induced a dramatic decrease in yield. With aminopyridines, reactivity was maintained and compounds **33** and **34** were isolated in 34% and 28% of yield, respectively. The sole limitation in this trend involved the use of 4-(4-fluorophenyl)-7,8-dihydro-1*H*-5,8-ethanopyrido[3,2-*d*]pyrimidinone **10** as starting material, which inhibited the reactivity whereas the tolyl derivative **9** restored the efficiency.

We next focused our attention on using this C–O activation strategy to create a C–C bond instead of a C–N bond under

palladium catalysis.^{28,40,41} In this tandem procedure, the PyBrop activation was achieved as previously described during 3 h and the reagents necessary to perform the cross coupling reaction were then added. Each parameter of the Suzuki–Miyaura reaction was modulated and the results are summarized in Table 5. 24 h of reaction with Pd(OAc)₂ at 110 °C in the presence of a bidentate phosphine proved to be a better catalytic system than with PdCl₂(dppf)·CH₂Cl₂ or Pd(PPh₃)₄ (entries 1–3). Modulation of the base indicated an increase in the yield using K₃PO₄ instead of classical carbonates (entries 3–6) whereas optimization of the nature of the ligand clearly indicated that Xantphos and Ruphos

gave the desired compound **39** in the best 68% yield under thermal conditions (entries 6–8). Finally, optimization under microwave irradiation (not shown) established that in the presence of Ruphos at 150 °C the reaction was achieved in only 1 h to furnish **39** in a 70% yield (entry 9).

In the last stage of this study, we investigated the modulation of the nature of the boron derivative to identify the potential

limitations. In fact, whatever the substituent on the phenyl boronic acid (*i.e.*, electron-donating or withdrawing), or the steric hindrance induced by an *ortho* substitution, the C–C bond was efficiently generated and products were isolated in fairly good yields ranging from 54% to 82% (Table 6, products **39**–**50**). The only identified limit concerned the presence of an acidic proton which slightly altered the yield of the reaction but this constraint was easily removed by the use of a protective group such as THP (entries 6–7). The use of (Het)arylboronic acids such as thiophene or pyridine was well tolerated and compounds **51** and **52** were isolated in 77 and 60% of yield, respectively. Finally, proportionally, the reactions conducted with substituted ethanopyrido[3,2-*d*]pyrimidinones **9**–**10** (entries 15–18) were less efficient than those conducted with **8** (entries 1 vs. 15 or 17, 10 vs. 16 or 18).

During our investigation, we were able to obtain single crystals of **49** suitable for X-ray diffraction analysis (Fig. 3). Compound **49** crystallizes in the monoclinic *P*2₁ space group with the following cell parameters: *a* = 15.385(8), *b* = 5.893(3), *c*

Fig. 3 View of the molecular structure of **49**. Only one of the two independent molecules of the asymmetric unit is shown (molecule B). The disorder on the CF₃ moiety is not represented for clarity. The labelling scheme of molecule A is the same but the suffix "b" has been replaced by suffix "a". The thermal atomic displacements are represented using ellipsoids at a 50% probability level.

$= 22.187(14) \text{ \AA}$, $\beta = 110.05(4)^\circ$ and $V = 1890(3) \text{ \AA}^3$. The asymmetric unit is composed of two independent molecules leading to four molecules in the unit cell.

Typical bond lengths are close to the expected values, ranging from 1.352(8) to 1.390(7) \AA for the C–C bonds and from 1.332(6) to 1.356(5) for N–C bonds within the aromatic rings, from 1.477(9) to 1.541(8) \AA , 1.430(6) to 1.488(7) and 1.309(9) to 1.336(10) for single C–C, C–N and C–F bonds respectively.

The pyrimidine and trifluoro-methyl-phenyl rings are almost coplanar with an angle between planes of $7.3(2)$ and $7.4(2)^\circ$ for the two independent molecules. Nevertheless, this angle may be underestimated as the trifluoro-methyl-phenyl ring appears slightly disordered. The second phenyl ring, meanwhile, is significantly tilted from the pyrimidine ring plane ($25.4(2)^\circ$ and $26.9(2)^\circ$) for both molecules. Fig. 3 shows one of the two independent molecules of **49** extracted from the crystal structure. The two molecules are very similar (RMSD = 0.452 \AA) except as regards the phenyl ring, which is reversely tilted in the two molecules.

Conclusions

In summary, the quick access to variously functionalized ethanopyrido[3,2-*d*]pyrimidines has been described herein. Aminated or arylated groups were introduced at the C-2 position of the ethanopyrido[3,2-*d*]pyrimidinones series using a tandem one-pot direct C–O activation sequence involving first PyBroP as activator and next a S_NAr or a palladium cross coupling reaction. Aminations were achieved under S_NAr reactions which were performed with a large variety of amines or using Buchwald–Hartwig cross-coupling reactions in combination with microwave irradiation. In addition, we have also reported the efficiency of the Suzuki–Miyaura reactions in C-2 position, which is compatible with all the boronylated starting material used. This work afforded a novel class of 1,4 disubstituted 7,8-dihydro-6*H*-5,8-ethanopyrido[3,2-*d*]pyrimidines which will undoubtedly have a major impact on the synthesis of new bioactive compounds that contain the rare ethanopyrido[3,2-*d*]pyrimidine scaffold as the central skeleton. Efforts to achieve these objectives are currently in progress.

Materials and methods

^1H NMR and ^{13}C NMR spectra were recorded on a Bruker DPX 250 or 400 Mhz instrument using CDCl_3 and $\text{DMSO}-d_6$. The chemical shifts are reported in parts per million (δ scale), and all coupling constant (J) values are reported in hertz. The following abbreviations were used for the multiplicities: s (singlet), d (doublet), t (triplet), q (quartet), p (pentuplet), m (multiplet), sext (sextuplet), and dd (doublet of doublets). Melting points are uncorrected. IR absorption spectra were obtained on a PerkinElmer PARAGON 1000 PC, and the values are reported in inverse centimeters. HRMS spectra were acquired in positive mode with an ESI source on a Q-TOF mass by the “Fédération de Recherche” ICOA/CBM (FR2708) platform. Monitoring of the reactions was performed using silica gel TLC plates (silica Merck 60 F 254). Spots were visualized by

UV light (254 nm and 356 nm). Column chromatography was performed using silica gel 60 (0.063–0.200 mm, Merck.). Microwave irradiation was carried out in sealed vessels placed in a Biotage Initiator or Biotage Initiator+ system (400 W maximum power). The temperatures were measured externally by IR. Pressure was measured by a non-invasive sensor integrated into the cavity lid. All reagents were purchased from commercial suppliers and were used without further purification. The crystal structure of **49** was solved by single crystal X-ray diffraction at room temperature using a Bruker Apex-II diffractometer with Mo- $K\alpha$ radiation. CCDC 2074887 contains the supplementary crystallographic data for this paper.

Synthetic procedures

General procedure A: aldol condensation. To a solution of 3-quinuclidinone hydrochloride (1.0 eq.) and sodium hydroxide (2.0 eq.) in a mixture of methanol/water (3/1) was added the corresponding aldehyde (1.2 eq.). General procedure B: S_NAr via PyBroP activation. In a microwave vial, to a solution of **8** (200 mg, 0.79 mmol, 1.0 eq.) and PyBroP (446 mg, 0.96 mmol, 1.2 eq.) in 1,4-dioxane (8 mL) was added Et₃N (0.32 mL, 2.36 mmol, 3.0 eq.). The mixture was then degassed by argon bubbling for 15 minutes. The sealed tube was heated at 100 °C for 3 h. After cooling, the corresponding amine (2.2 eq.) was added, and the reaction mixture was heated at 100 °C for 17 h. After cooling to room temperature, the solvent was evaporated under reduced atmosphere. The crude material was purified by flash chromatography on silica gel to give the desired compound.

General procedure C: Buchwald–Hartwig cross coupling via PyBroP activation. In a microwave vial, to an argon-degassed solution of **8** (253 mg, 1.00 mmol, 1.0 eq.) and PyBroP (559 mg, 1.20 mmol, 1.2 eq.) in 1,4-dioxane (10 mL), was added Et_3N (0.40 mL, 2.96 mmol, 3.0 eq.). The reaction was heated for 3 h at 100 °C. After cooling, K_2CO_3 (276 mg, 2.00 mmol, 2.0 eq.), the required amine (1.5.0 eq.), $\text{Pd}(\text{OAc})_2$ (22 mg, 0.10 mmol, 0.1 eq.) and Xantphos (116 mg, 0.20 mmol, 0.2 eq.) were added to the reaction mixture. The sealed tube was heated at 130 °C for 1 h under microwave irradiation. After cooling to room temperature, the solvent was evaporated under reduced pressure and the crude material was diluted in DCM (20 mL). The organic layer was washed with water (2×20 mL), dried over MgSO_4 , filtered, and concentrated under vacuum. The crude mixture was purified by flash chromatography on silica gel to obtain the desired compound.

General procedure D: Suzuki–Miyaura cross-coupling. In a microwave vial, to an argon-degassed solution of **8** (200 mg, 0.79 mmol, 1.0 eq.) and PyBroP (446 mg, 0.96 mmol, 1.2 eq.) in 1,4-dioxane (8 mL), was added Et_3N (0.32 mL, 239 mg, 2.36 mmol, 3.0 eq.) and the reaction was heated for 3 h at 100 °C. After cooling, a solution of K_3PO_4 (849 mg, 4.00 mmol, 5.0 eq.) in H_2O (2 mL), the required arylboronic acid (2.0 eq.), $\text{Pd}(\text{OAc})_2$ (18 mg, 0.08 mmol, 0.1.0 eq.) and RuPhos (74 mg, 0.16 mmol, 0.2 eq.) were added to the reaction mixture. The sealed tube was heated at 150 °C for 1 h under microwave irradiation. After cooling to room temperature, the solvent was evaporated under reduced pressure and the crude material was diluted in DCM (20 mL). The organic layer was washed with water (2 \times 20 mL), dried over MgSO_4 , filtered, and concentrated under vacuum. The crude mixture was purified by flash chromatography on silica gel to obtain the desired compound.

4-Phenyl-2-(*p*-tolyl)-7,8-dihydro-6H-5,8-ethanopyrido[3,2-*d*]pyrimidine (**39**). Compound **39** was obtained according to the general procedure D using *p*-tolylboronic acid (239 mg, 1.60 mmol, 2.0 eq.). After purification by silica gel flash chromatography (PE/EA, 90/10), **39** (182 mg, 70%) was obtained as a white solid. Rf (PE/EA: 90/10): 0.40. M_p : 192–194 °C.
