# Mechanochemical synthesis of air-stable hexagonal $\text{Li}_4\text{SnS}_4$ -based solid electrolytes containing $\text{LiI}$ and $\text{Li}_3\text{PS}_4$ †

Misae Otoyama, \* Kentaro Kuratani  and Hironori Kobayashi 

Sulfide solid electrolytes with high ionic conductivity and high air stability must be developed for manufacturing sulfide all-solid-state batteries.  $\text{Li}_{10}\text{GeP}_2\text{S}_{12}$ -type and argyrodite-type solid electrolytes exhibit a high ionic conductivity of  $\sim 10^{-2} \text{ S cm}^{-1}$  at room temperature, while emitting toxic  $\text{H}_2\text{S}$  gas when exposed to air. We focused on hexagonal  $\text{Li}_4\text{SnS}_4$  prepared by mechanochemical treatment because it comprises air-stable  $\text{SnS}_4$  tetrahedra and shows higher ionic conductivity than orthorhombic  $\text{Li}_4\text{SnS}_4$  prepared by solid-phase synthesis. Herein, to enhance the ionic conductivity of hexagonal  $\text{Li}_4\text{SnS}_4$ ,  $\text{LiI}$  was added to  $\text{Li}_4\text{SnS}_4$  by mechanochemical treatment. The ionic conductivity of  $0.43\text{LiI} \cdot 0.57\text{Li}_4\text{SnS}_4$  increased by 3.6 times compared with that of  $\text{Li}_4\text{SnS}_4$ . XRD patterns of  $\text{Li}_4\text{SnS}_4$  with  $\text{LiI}$  showed peak-shifting to lower angles, indicating that introduction of  $\text{I}^-$ , which has a large ionic radius, expanded the  $\text{Li}$  conduction paths. Furthermore,  $\text{Li}_3\text{PS}_4$ , which is the most air-stable in the  $\text{Li}_2\text{S}-\text{P}_2\text{S}_5$  system and has higher ionic conductivity than  $\text{Li}_4\text{SnS}_4$ , was added to the  $\text{LiI}-\text{Li}_4\text{SnS}_4$  system. We found that  $0.37\text{LiI} \cdot 0.25\text{Li}_3\text{PS}_4 \cdot 0.38\text{Li}_4\text{SnS}_4$  sintered at  $200^\circ\text{C}$  showed the highest ionic conductivity of  $5.5 \times 10^{-4} \text{ S cm}^{-1}$  at  $30^\circ\text{C}$  in the hexagonal  $\text{Li}_4\text{SnS}_4$ -based solid electrolytes. The rate performance of an all-solid-state battery using  $0.37\text{LiI} \cdot 0.25\text{Li}_3\text{PS}_4 \cdot 0.38\text{Li}_4\text{SnS}_4$  heated at  $200^\circ\text{C}$  was higher than those obtained using  $\text{Li}_4\text{SnS}_4$  and  $0.43\text{LiI} \cdot 0.57\text{Li}_4\text{SnS}_4$ . In addition, it exhibited similar air stability to  $\text{Li}_4\text{SnS}_4$  by formation of  $\text{LiI} \cdot 3\text{H}_2\text{O}$  in air. Therefore, addition of  $\text{LiI}$  and  $\text{Li}_3\text{PS}_4$  to hexagonal  $\text{Li}_4\text{SnS}_4$  by mechanochemical treatment is an effective way to enhance ionic conductivity without decreasing the air stability of  $\text{Li}_4\text{SnS}_4$ .

## Introduction

High performance all-solid-state lithium batteries are desirable to realize safe and large-scale power sources of electric vehicles and energy storage systems.<sup>1,2</sup> Compared with oxide solid electrolytes, sulfide solid electrolytes have attracted significant attention because they show higher ionic conductivities, especially in LGPS-type (e.g.  $\text{Li}_{10}\text{GeP}_2\text{S}_{12}$  ( $12 \text{ mS cm}^{-1}$ )<sup>3</sup> and  $\text{Li}_{9.54}\text{Si}_{1.74}\text{P}_{1.44}\text{S}_{11.7}\text{Cl}_{0.3}$  ( $25 \text{ mS cm}^{-1}$ )<sup>4</sup>), argyrodite-type (e.g.  $\text{Li}_{5.5}\text{PS}_{4.5}\text{Cl}_{1.5}$  ( $12 \text{ mS cm}^{-1}$ )<sup>5</sup>), and  $\text{Li}_2\text{S}-\text{P}_2\text{S}_5$  systems (e.g.  $\text{Li}_7\text{P}_3\text{S}_{11}$  ( $17 \text{ mS cm}^{-1}$ )<sup>6,7</sup>). Moreover, their high deformability enables the development of sufficient solid-solid contacts by cold pressing.<sup>8,9</sup> However, the low air stability of sulfide solid electrolytes increases the risks of toxic  $\text{H}_2\text{S}$  gas generation when they are exposed to air. Sahu *et al.* reported that the stability of sulfide solid electrolytes to moisture in air depends on the hard and soft acids and bases (HSAB) theory.<sup>10</sup> Based on the HSAB

theory, sulfide solid electrolytes with soft acids such as  $\text{Sb}$ ,  $\text{As}$ , and  $\text{Sn}$  show higher air stability than those with hard acids such as  $\text{P}$  because the former prevent the replacement of sulfur (soft base) in solid electrolytes with oxygen (hard base) in air.  $\text{Li}_4\text{SnS}_4$ -based solid electrolytes have been especially investigated due to their relatively high ionic conductivity and high air stability.<sup>10–18</sup>

Kaib *et al.* reported that orthorhombic  $\text{Li}_4\text{SnS}_4$  prepared by solid-phase synthesis showed ionic conductivity of  $7 \times 10^{-5} \text{ S cm}^{-1}$  at  $20^\circ\text{C}$ .<sup>11</sup> Ionic conductivity of orthorhombic  $\text{Li}_4\text{SnS}_4$  increases by the partial substitution of group 15 elements for  $\text{Sn}$ .  $\text{Li}_{3.833}\text{Sn}_{0.833}\text{As}_{0.166}\text{S}_4$  (ref. 10) and  $\text{Li}_{3.85}\text{Sn}_{0.85}\text{Sb}_{0.15}\text{S}_4$  (ref. 16) prepared by solid-phase syntheses exhibit ionic conductivities of  $1.39 \times 10^{-3} \text{ S cm}^{-1}$  at  $25^\circ\text{C}$  and  $8.5 \times 10^{-4} \text{ S cm}^{-1}$  at  $30^\circ\text{C}$ , respectively. In contrast, the substitution of group 13 elements such as  $\text{Ga}$  and  $\text{Al}$  results in low ionic conductivity of  $10^{-6} \text{ S cm}^{-1}$ .<sup>19,20</sup> In solid-phase synthesis, only a few toxic elements such as  $\text{As}$  and  $\text{Sb}$  enhance the ionic conductivity of  $\text{Li}_4\text{SnS}_4$ .

Park *et al.* reported that  $0.4\text{LiI} \cdot 0.6\text{Li}_4\text{SnS}_4$  glass can be synthesized by dissolving  $\text{LiI}$  and orthorhombic  $\text{Li}_4\text{SnS}_4$  in ethanol and *via* subsequent heat treatment.<sup>12</sup> Furthermore,  $0.4\text{LiI} \cdot 0.6\text{Li}_4\text{SnS}_4$  glass has an ionic conductivity of  $4.1 \times 10^{-4} \text{ S cm}^{-1}$  at  $30^\circ\text{C}$  and high deformability. As  $\text{Li}_4\text{SnS}_4$  shows

high stability to moisture, Choi *et al.* coated  $\text{Li}_4\text{SnS}_4$  on  $\text{LiCoO}_2$  prepared from aqueous solution<sup>13</sup> and Matsuda *et al.* synthesized  $\text{Li}_4\text{SnS}_4$  by ion-exchange of  $\text{Na}_4\text{SnS}_4$  aqueous solution.<sup>18</sup>

Hexagonal  $\text{Li}_4\text{SnS}_4$  reported as the metastable phase is synthesized by mechanochemical treatment of  $\text{Li}_2\text{S}$  and  $\text{SnS}_2$ .<sup>14</sup> Sintered bodies of hexagonal  $\text{Li}_4\text{SnS}_4$  showed a higher ionic conductivity of  $1.1 \times 10^{-4} \text{ S cm}^{-1}$  at 25 °C than orthorhombic  $\text{Li}_4\text{SnS}_4$  prepared by solid-phase synthesis. To further increase the ionic conductivity, we focused on the addition of other components to hexagonal  $\text{Li}_4\text{SnS}_4$  by mechanochemical treatment.

In the present study,  $x\text{LiI} \cdot (1-x)\text{Li}_4\text{SnS}_4$  solid electrolytes were prepared by mechanochemical treatment. Addition of LiI increases ionic conductivity and formability, as has been reported in  $\text{Li}_2\text{S}$ – $\text{P}_2\text{S}_5$  systems.<sup>21–25</sup> While  $x\text{LiI} \cdot (1-x)\text{Li}_4\text{SnS}_4$  glass was obtained by liquid-phase synthesis,<sup>12</sup> we found that the crystal phase was obtained by mechanochemical treatment. To further improve the ionic conductivity without reducing the stability of the  $\text{Li}_4\text{SnS}_4$ -based solid electrolytes under air,  $\text{LiI}$ – $\text{Li}_3\text{PS}_4$ – $\text{Li}_4\text{SnS}_4$  solid electrolytes were prepared.  $\text{Li}_3\text{PS}_4$  was selected since it exhibits the highest air stability in  $\text{Li}_2\text{S}$ – $\text{P}_2\text{S}_5$  systems because it consists of only  $\text{PS}_4$  tetrahedra.<sup>26</sup> In addition,  $\text{Li}_3\text{PS}_4$  glass was selected because it shows a relatively high ionic conductivity ( $\sim 4 \times 10^{-4} \text{ S cm}^{-1}$  at 25 °C) compared to other  $\text{Li}_2\text{S}$ – $\text{P}_2\text{S}_5$  systems.<sup>27</sup> In addition, the air stabilities of the prepared solid electrolytes were compared. The purpose of the present study was to develop novel hexagonal  $\text{Li}_4\text{SnS}_4$ -based solid electrolytes with both high air stability and ionic conductivity through mechanochemical treatment.

## Experimental

### Preparation of solid electrolytes

We prepared  $x\text{LiI} \cdot (1-x)\text{Li}_4\text{SnS}_4$  ( $x = 0, 0.40\text{--}0.50$ ),  $y\text{Li}_3\text{PS}_4 \cdot (1-y)\text{Li}_4\text{SnS}_4$  ( $y = 0\text{--}0.5$ ) and  $z\text{LiI} \cdot (1-z)(0.4\text{Li}_3\text{PS}_4 \cdot 0.6\text{Li}_4\text{SnS}_4)$  ( $z = 0.37\text{--}0.50$ ) solid electrolytes by mechanochemical treatment. The mixtures (0.5 g) of  $\text{Li}_2\text{S}$  (99.9%; Mitsuwa Chemical Co., Ltd),  $\text{SnS}_2$  (99.5%; Mitsuwa Chemical Co., Ltd),  $\text{LiI}$  (ultra dry, 99.999%; Alfa Aesar), and  $\text{P}_2\text{S}_5$  (Merck) were placed in a  $\text{ZrO}_2$  pot (45 mL) with  $\text{ZrO}_2$  balls (4 mm $\Phi$ , 90 g) in a dry Ar atmosphere. They were mechanically milled at 510 rpm for 10–60 h using a planetary ball mill apparatus (Pulverisette 7; Fritsch). Furthermore, the samples with  $x = 0, 0.43, z = 0.37$ , and  $0.43$  were heated at 390 °C, 200/270 °C, 200/240 °C, and 230 °C, respectively, for 2 h in an Ar atmosphere to obtain heat-treated samples.  $\text{Li}_{5.5}\text{PS}_{4.5}\text{Cl}_{1.5}$  solid electrolytes were prepared by mechanochemical treatment of  $\text{Li}_2\text{S}$ ,  $\text{P}_2\text{S}_5$ , and  $\text{LiI}$  (99.9%; Kojundo Chemical Laboratory Co., Ltd). The starting materials are put in a  $\text{ZrO}_2$  pot (250 mL) with 12  $\text{ZrO}_2$  balls (20 mm $\Phi$ ) and milled at 330 rpm for 30 h using a planetary ball mill apparatus (Pulverisette 5; Fritsch).  $\text{Li}_3\text{PS}_4$  glass was prepared by mechanochemical treatment of  $\text{Li}_2\text{S}$  and  $\text{P}_2\text{S}_5$  with heptane and dibutyl ether. The details are in the previous reports.<sup>28</sup>

### Characterization of solid electrolytes

XRD measurements were conducted for the prepared solid electrolytes using an X-ray diffractometer (D8 ADVANCE; Bruker AXS) with  $\text{Cu K}\alpha$  radiation. Furthermore, synchrotron XRD

measurements were performed for the samples with  $x = 0, 0.40$  and  $0.43$  in  $x\text{LiI} \cdot (1-x)\text{Li}_4\text{SnS}_4$  at the BL19B2 beamline of SPring-8 at room temperature ( $\sim 25$  °C) with a wavelength of 0.5002 Å to obtain their crystallographic data. The samples were sealed in quartz capillaries ( $\sim 0.3$  mm in diameter) in a dry Ar atmosphere. Rietveld refinement was performed using the RIETAN-FP program.<sup>29</sup> In addition, pair distribution function (PDF) analysis was conducted for the samples with  $x = 0$  and  $0.43$  using an X-ray diffractometer (SmartLab; Rigaku Corp.) with  $\text{Mo K}\alpha$  radiation.

Raman spectroscopy was performed for the samples with  $x = 0$  and  $0.43$  using a Raman microscope (inVia Raman Microscope; RENISHAW) with a green laser (532 nm) and a  $50\times$  objective lens ( $\text{NA} = 0.50$ , Leica Microsystems).

We plotted DSC curves of the samples with prepared solid electrolytes using a thermal analyzer (DSC-60 Plus; Simadzu Corp.). The samples were sealed with an Al pan in a dry Ar atmosphere and heated up to 500 °C from room temperature at a heating rate of  $10$  °C  $\text{min}^{-1}$ .

To evaluate the ionic conductivity of the prepared solid electrolytes, AC impedance measurements were performed with an applied voltage of 50 mV and a frequency range of 10 Hz–10 MHz using an impedance analyzer (1260A; Solartron Analytical). The samples were pelletized to a diameter of 10 mm at 360 MPa for 5 min. To measure the sample with  $z = 0.37$  in  $z\text{LiI} \cdot (1-z)(0.4\text{Li}_3\text{PS}_4 \cdot 0.6\text{Li}_4\text{SnS}_4)$  heated at 200 and 240 °C, pelletized samples were heated to obtain sintered bodies. The samples were sandwiched with stainless steel (SUS) rods as current collectors.

For cyclic voltammetry (CV) measurements, an asymmetric cell (Li/solid electrolyte/SUS) was prepared. The solid electrolyte layer was prepared by uniaxially pressing at 360 MPa for 5 min. The Li foil (8 mm in diameter) was attached to the solid electrolyte layer and pressed at 72 MPa for 2 min as a reference and a counter electrode. The other side of the solid electrolyte layer was directly attached to the SUS rod (working electrode). CV measurements were conducted for the cells with a potential sweep varying from  $-0.5$  to  $5.0$  V and a scanning rate of  $1 \text{ mV s}^{-1}$  at 25 °C using an electrochemical measurement device (Celltest System 1470 E; Solartron Analytical).

### Construction of all-solid-state cells

All-solid-state cells were constructed with composite positive electrodes consisting of the solid electrolytes with  $x = 0, 0.43$  or  $z = 0.37$  (heated at 200 °C) and a  $\text{LiNi}_{1/3}\text{Mn}_{1/3}\text{Co}_{1/3}\text{O}_2$  (NMC) positive electrode to compare battery performance. The composite positive electrodes were prepared by mixing solid electrolytes and  $\text{LiNbO}_3$ -coated NMC at a weight ratio of 30/70.  $\text{LiNbO}_3$  was used as the buffer layer because it can reduce the interfacial resistance between sulfide solid electrolytes and NMC.<sup>30</sup>  $\text{LiNbO}_3$  coating was prepared by spray coating of an ethanol solution of lithium niobium ethoxide and subsequent heat treatment at 400 °C for 30 min under  $\text{O}_2$  flow.<sup>28,30</sup> The  $\text{Li}_3\text{PS}_4$  glass solid electrolyte (80 mg) was pressed at 36 MPa to prepare a solid electrolyte layer. The composite positive electrode (10 mg) was placed on the solid electrolyte layer and uniaxially pressed at 360 MPa for 5 min. An indium foil (99.999%;  $0.1 \text{ mm}^2$ ; Furuuchi Chemical Corp.) ( $\phi = 9 \text{ mm}$ ) and a lithium piece (99.9%,  $0.2$

mm<sup>2</sup>; Honjo Metal Co., Ltd) (1 mg) were placed on the opposite sides and pressed at 180 MPa for 2 min. The cells (diameter in 10 mm) were sandwiched with the SUS rods and operated at 30 °C with a cut-off voltage of 2.4–3.6 V (vs. Li–In) at 0.1, 0.2, 0.5 and 1C rates (1C = 0.9–1.0 mA) using a charge–discharge measuring device (ABE 1024-5V; Electro Field Co., Ltd).

### Air stability test of solid electrolytes

To evaluate the air stability of the solid electrolytes, H<sub>2</sub>S gas generation was monitored in a sealed chamber (2000 mL) with a relative humidity of 50% at 25 °C. The solid electrolyte powder (50 mg), a small fan, and an H<sub>2</sub>S gas sensor (Gasman; Crowcon Detection Instruments Ltd) were placed in the chamber. The amount of H<sub>2</sub>S gas (ppm) was monitored by the H<sub>2</sub>S gas sensor. The generated H<sub>2</sub>S gas volume ( $V$ ; cm<sup>3</sup> g<sup>−1</sup>) was calculated using the following equation:  $V = (C \times L \times 10^{-6})/m$ ,<sup>14</sup> where  $C$  is the concentration of H<sub>2</sub>S gas (ppm),  $L$  is the volume of the chamber (cm<sup>3</sup>), and  $m$  is the weight of the solid electrolyte powder (g). Structures of air-exposed samples were examined by XRD measurements. The samples were exposed in air at 50% RH for 3 min, then sealed in an XRD holder in air, and measured for 60 min.

## Results and discussion

### Preparation and characterization of solid electrolytes in the LiI–Li<sub>4</sub>SnS<sub>4</sub> system

The structures of the prepared  $x\text{LiI} \cdot (1-x)\text{Li}_4\text{SnS}_4$  ( $x = 0$  and  $0.40 \leq x \leq 0.50$ ) solid electrolytes were examined by XRD measurements (Fig. 1). The diffraction peaks of hexagonal Li<sub>4</sub>SnS<sub>4</sub> observed at  $x = 0$  shifted to a lower angle after the addition of LiI because I<sup>−</sup> with a large ionic radius was introduced into the structure. In addition, a new peak appeared at approximately 28–29°. The XRD simulation (not shown here) showed that the intensity of the peak at 28–29° increased with increasing Li/Sn occupation ratio. Therefore, the new peak may be attributed to the increase in the Li/Sn ratio due to the addition of LiI. The XRD patterns of the  $x = 0.45$  and  $x = 0.50$  samples showed small diffraction peaks of LiI·H<sub>2</sub>O (ICSD #25515), indicating that LiI could not dissolve in Li<sub>4</sub>SnS<sub>4</sub> completely in the case of more than  $x = 0.45$ .

The  $x\text{LiI} \cdot (1-x)\text{Li}_4\text{SnS}_4$  solid electrolytes can be prepared from not only Li<sub>2</sub>S, SnS<sub>2</sub>, and LiI but also from hexagonal or orthorhombic Li<sub>4</sub>SnS<sub>4</sub> and LiI as starting materials. Fig. S1 in the ESI† shows XRD patterns of 0.4LiI·0.6Li<sub>4</sub>SnS<sub>4</sub> prepared from LiI and hexagonal Li<sub>4</sub>SnS<sub>4</sub> or orthorhombic Li<sub>4</sub>SnS<sub>4</sub>, which

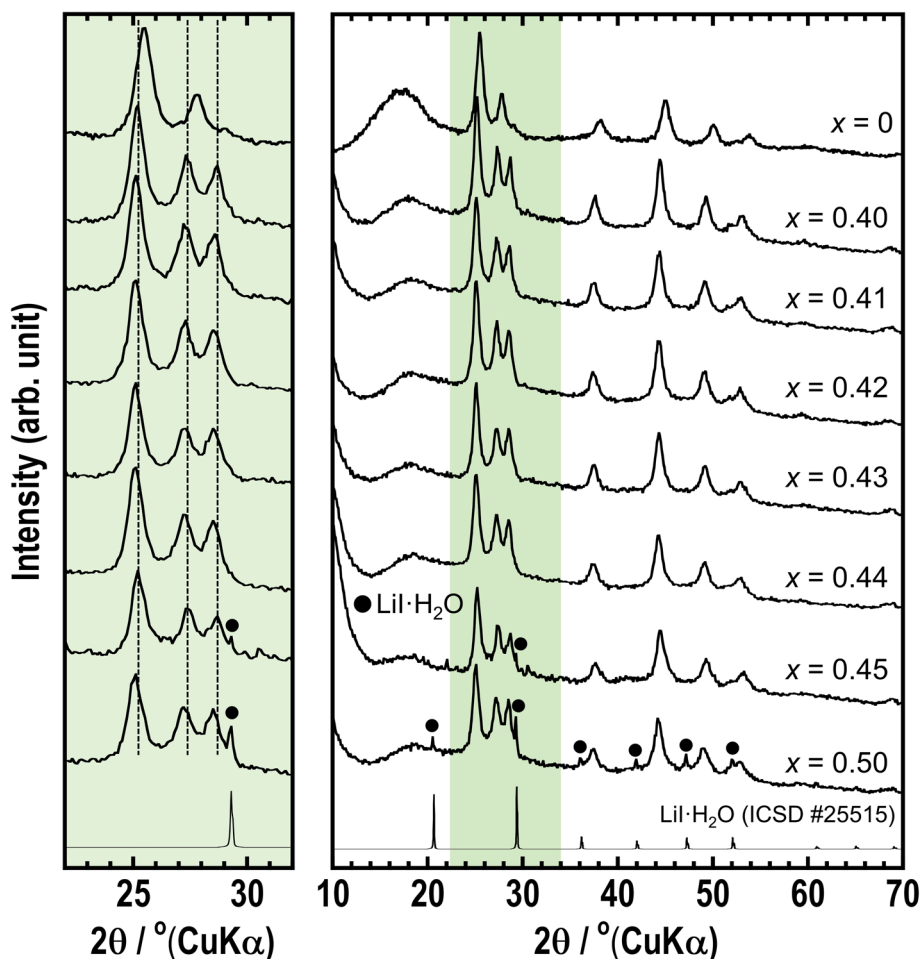

Fig. 1 XRD patterns of  $x\text{LiI} \cdot (1-x)\text{Li}_4\text{SnS}_4$  ( $x = 0, 0.40–0.50$ ). The left part is the enlarged XRD pattern between 22–32°.

were prepared by heat treatment of hexagonal  $\text{Li}_4\text{SnS}_4$ . These  $0.4\text{LiI} \cdot 0.6\text{Li}_4\text{SnS}_4$  samples showed similar XRD patterns as the  $0.4\text{LiI} \cdot 0.6\text{Li}_4\text{SnS}_4$  sample prepared from  $\text{Li}_2\text{S}$ ,  $\text{SnS}_2$ , and  $\text{LiI}$ . Moreover, we also confirmed that orthorhombic  $\text{Li}_4\text{SnS}_4$  prepared by the solid-phase synthesis of  $\text{Li}_2\text{S}$  and  $\text{SnS}_2$  could be used as a starting material of  $x\text{LiI} \cdot (1-x)\text{Li}_4\text{SnS}_4$  solid electrolytes (not shown here).

Ionic conductivities of cold-pressed  $x\text{LiI} \cdot (1-x)\text{Li}_4\text{SnS}_4$  were measured by the AC impedance technique (Table S1†). Fig. S2† shows the Nyquist plots of the sample with  $x = 0.43$  at  $25^\circ\text{C}$ . The conductivity was determined from the total resistance ( $R_{\text{total}} = R_{\text{b}} + R_{\text{g.b.}}$ ) because the resistances of bulk ( $R_{\text{b}}$ ) and grain boundaries ( $R_{\text{g.b.}}$ ) could not be distinguished. Addition of  $\text{LiI}$  to  $\text{Li}_4\text{SnS}_4$  enhanced their ionic conductivity ( $\sim 1 \times 10^{-4} \text{ S cm}^{-1}$  at  $25^\circ\text{C}$ ) compared with  $\text{Li}_4\text{SnS}_4$  ( $4.5 \times 10^{-5} \text{ S cm}^{-1}$  at  $25^\circ\text{C}$ ). The ionic conductivities of  $x = 0.40$ – $0.50$  in  $x\text{LiI} \cdot (1-x)\text{Li}_4\text{SnS}_4$  at  $25^\circ\text{C}$  and  $60^\circ\text{C}$  are plotted in Fig. 2a. The sample where  $x = 0.43$  exhibited the highest ionic conductivity of  $1.6 \times 10^{-4} \text{ S cm}^{-1}$  at

$25^\circ\text{C}$  due to the greater amount of dissolved  $\text{LiI}$ , whereas at  $x = 0.50$ , the ionic conductivity was reduced due to the remaining  $\text{LiI}$ .

We also prepared  $\text{Li}_2\text{S}$ – $\text{SnS}_2$  solid electrolytes with  $\text{Li}_2\text{S}/\text{SnS}_2$  amounts of 70/30 and 80/20 (mol%). Note that the ratio of 67/33 indicates  $\text{Li}_4\text{SnS}_4$ . The XRD patterns of the 70/30 and 80/20 solid electrolytes indicated that  $\text{Li}_2\text{S}$  remained (Fig. S3a†), and their ionic conductivities were lower than those of the 67/33 sample (Table S2†). Therefore, increasing the amount of  $\text{Li}_2\text{S}$  in the  $\text{Li}_2\text{S}$ – $\text{SnS}_2$  system is not an effective way to increase the Li carrier and ionic conductivity. Furthermore, addition of  $\text{LiI}$  to the 70/30 and 80/20 solid electrolytes increased their ionic conductivities— $7.3 \times 10^{-5}$  and  $5.8 \times 10^{-5} \text{ S cm}^{-1}$ , respectively at  $25^\circ\text{C}$ —although they were lower than that of the 67/33 solid electrolyte with  $\text{LiI}$  (Fig. S3b and Table S2†).

We focused on  $x = 0.43$  in  $x\text{LiI} \cdot (1-x)\text{Li}_4\text{SnS}_4$  exhibiting the highest ionic conductivity hereafter. Synchrotron XRD, PDF analysis, and Raman spectroscopy were conducted for the  $x =$

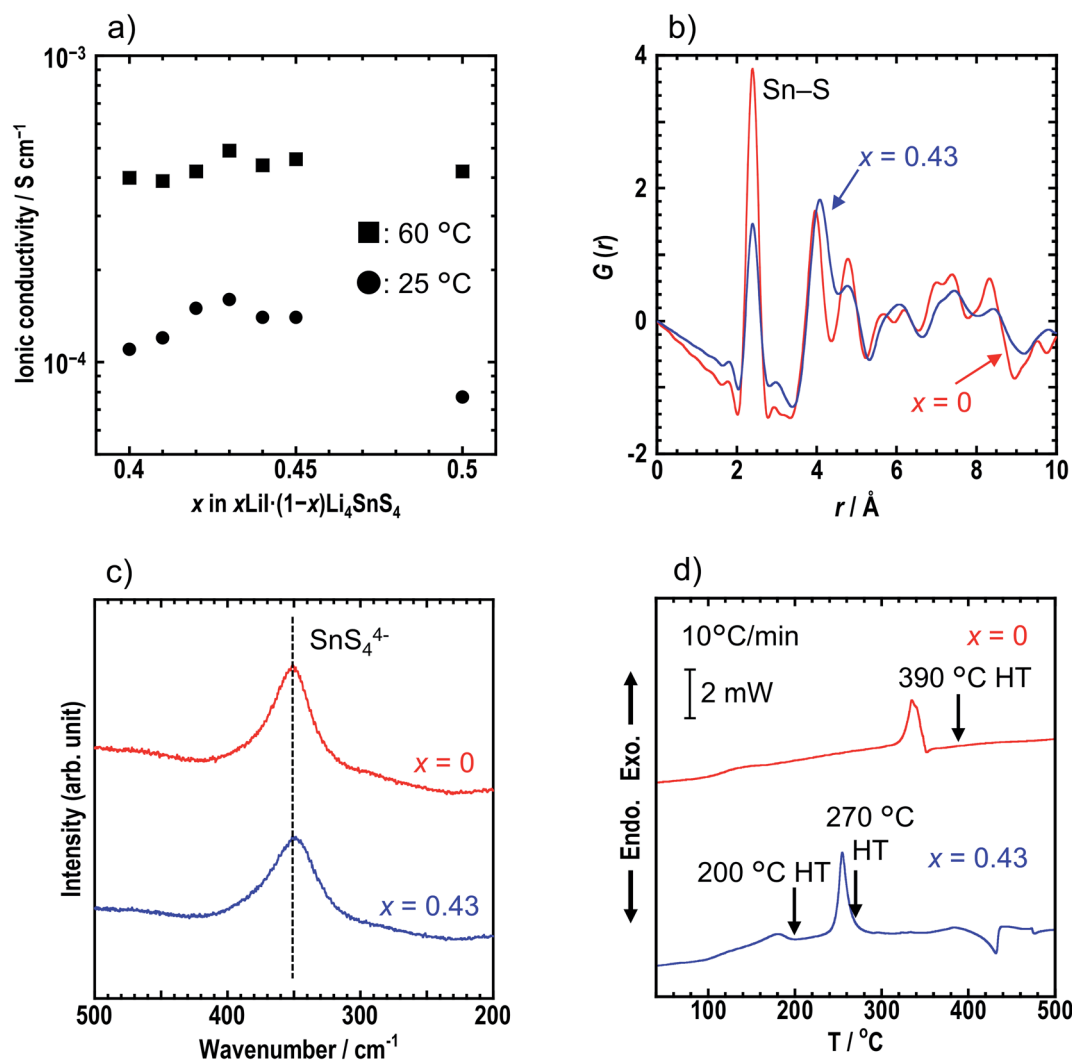

Fig. 2 (a) The ionic conductivities of  $x = 0.40$ – $0.50$  in  $x\text{LiI} \cdot (1-x)\text{Li}_4\text{SnS}_4$  at  $25^\circ\text{C}$  and  $60^\circ\text{C}$ . (b)  $G(r)$  and (c) Raman spectra of  $x = 0$  and  $0.43$  in  $x\text{LiI} \cdot (1-x)\text{Li}_4\text{SnS}_4$ . The Sn–S correlation in the  $\text{SnS}_4$  tetrahedra corresponds to  $r = 2.4 \text{ \AA}$ . (d) DSC curves of  $x = 0$  and  $0.43$ . The heating rate was  $10^\circ\text{C min}^{-1}$ . The arrows indicate heat treatment (HT) temperatures for heat-treated samples.

0 and  $x = 0.43$  samples to compare their structures in detail. Fig. S4† shows the synchrotron XRD patterns and structures of the  $x = 0$ , 0.40, and 0.43 samples characterized by Rietveld refinement. Crystallographic data of  $x = 0$ , 0.40, and 0.43 are shown in Tables S3, S4, and S5,† respectively. All samples were determined as  $P6_3/mmc$  space group irrespective of the presence of LiI. The samples with LiI were refined by partial replacement of S by I. The lattice volume increased with the addition of LiI, suggesting that  $I^-$ , which has a large radius, was introduced into the structure and that LiI-added  $Li_4SnS_4$  formed solid solutions. The occupancies of Li were not determined in the present study. Rietveld analysis was conducted for both  $x = 0.40$  and 0.43 with an Li occupation rate of 0.375 based on a previous

report on  $Li_4SnS_4$ .<sup>14</sup> To investigate the local structure, PDF analyses were conducted for  $x = 0$  and  $x = 0.43$  samples using a laboratory X-ray diffractometer with Mo K $\alpha$  radiation. The  $G(r)$  of  $x = 0$  and 0.43 samples are shown in Fig. 2b. Both samples showed the first peak at  $\sim 2.1$  Å, corresponding to the Sn–S correlation in the  $SnS_4$  tetrahedra.<sup>11</sup> In addition, both samples showed a Raman band at  $350\text{ cm}^{-1}$  which was attributed to the  $SnS_4^{4-}$  unit (Fig. 2c).<sup>31</sup> Note that the Raman band of the  $x = 0.43$  sample is slightly broader than that of the  $x = 0$  sample. The results of the first peak in PDF analysis and the Raman spectra suggest that the  $SnS_4$  tetrahedra mostly remain unchanged by the addition of LiI. However, the second peak of  $x = 0.43$  in the PDF analysis is observed at a longer distance than that of  $x = 0$ ,

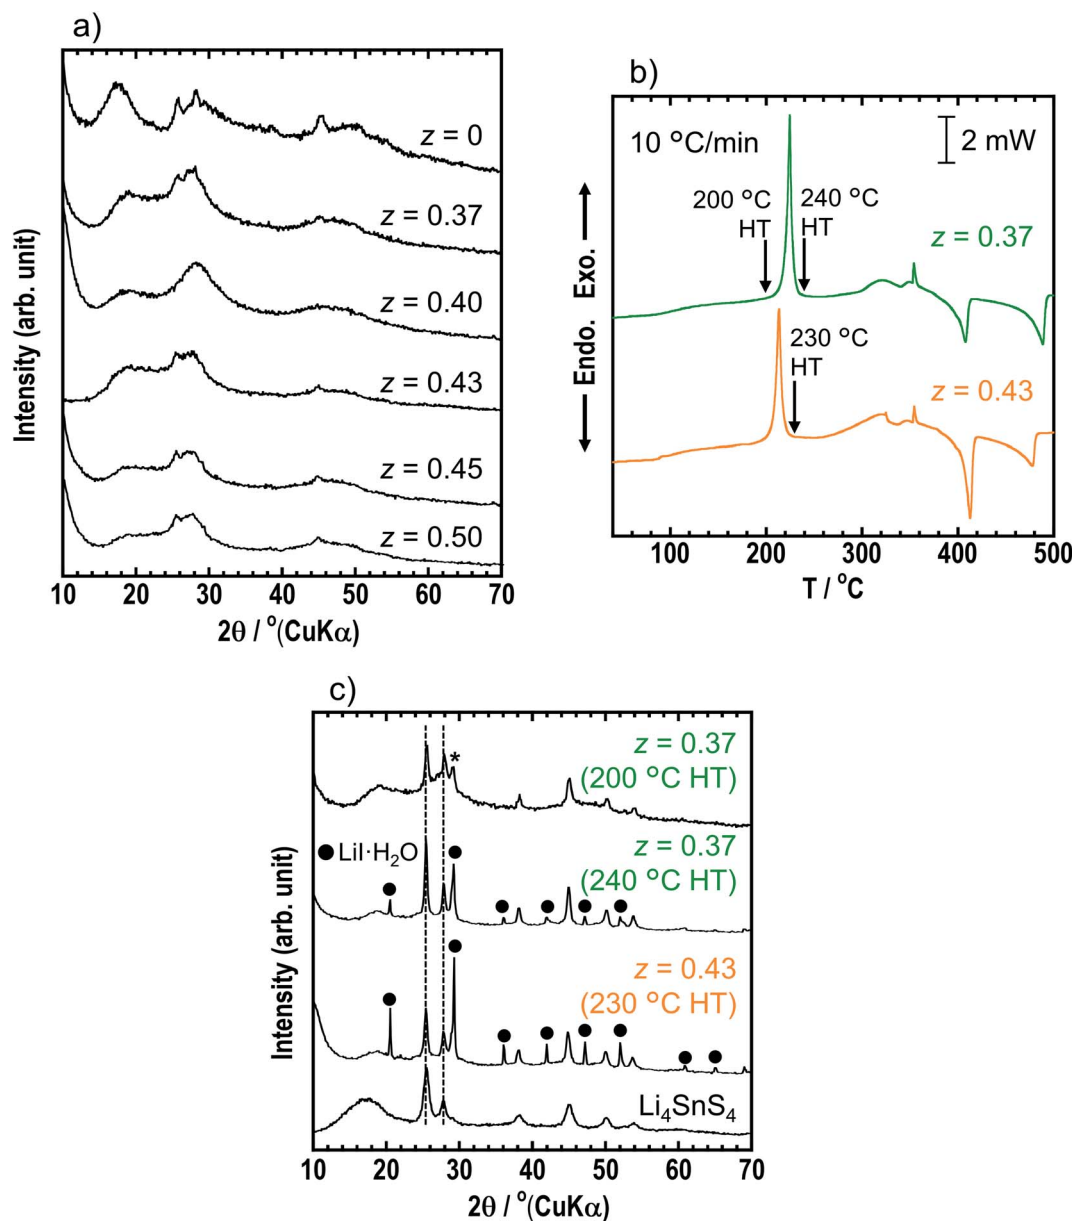

Fig. 3 (a) XRD patterns of  $z = 0, 0.37, 0.40, 0.43, 0.45$  and  $0.50$  in as-milled  $zLiI \cdot (1-z)(0.4Li_3PS_4 \cdot 0.6Li_4SnS_4)$ . (b) DSC curves of  $z = 0.37$  and  $0.43$ . The heating rate was  $10\text{ }^\circ\text{C min}^{-1}$ . The arrows indicated heat treatment (HT) temperatures for heat-treated samples. (c) XRD patterns of  $z = 0.37$  and  $0.43$  heated at  $200/240\text{ }^\circ\text{C}$  and  $230\text{ }^\circ\text{C}$ , respectively and  $Li_4SnS_4$ .

suggesting that iodine exists outside of the  $\text{SnS}_4$  tetrahedra but near S in the  $\text{SnS}_4$  tetrahedra. From the Faber–Ziman coefficient in  $x = 0.43$ , the  $w_{ij}$  values of the S–S and S–I correlations are 0.145 and 0.18, respectively, indicating that it is hard to distinguish between S–S and S–I bonds. Regarding previous studies on PDF analysis of LiI-added  $\text{Li}_3\text{PS}_4$ , Takahashi *et al.* reported that iodine was inserted between  $\text{PS}_4$  anions in the  $70\text{Li}_3\text{PS}_4 \cdot 30\text{LiI}$  (mol%) solid electrolytes because it showed no peak from the P–I bond in the exchanged S and I model.<sup>32</sup> Similarly, in the case of  $\text{Li}_4\text{SnS}_4$ , iodine was assumed to exist between the  $\text{SnS}_4$  anion, while  $\text{Li}_4\text{SnS}_4$  with LiI was refined by partial replacement of S by I, as observed in the XRD results. Further refinement by maximum entropy methods will reveal new site of iodine in the structure. The results of the XRD, PDF, and Raman measurements suggest that iodine was introduced between  $\text{SnS}_4$  tetrahedra and caused expansion of diffusion paths of  $\text{Li}^+$ , resulting in higher ionic conductivity.

Thermal behaviors of  $x = 0$  and  $x = 0.43$  were examined by DSC measurements (Fig. 2d). The DSC curve of  $x = 0.43$  shows two exothermic peaks at 180 °C and 260 °C, whereas the  $x = 0$  sample has a peak at 340 °C. Hexagonal and orthorhombic  $\text{Li}_4\text{SnS}_4$  were obtained by heat treatment of as-milled  $\text{Li}_4\text{SnS}_4$  at 260 °C and 390 °C, respectively.<sup>14</sup> Fig. S5† shows XRD patterns of  $x = 0$  and  $x = 0.43$  samples before and after heat treatment. In the present study, orthorhombic  $\text{Li}_4\text{SnS}_4$  was obtained by heat treatment at 390 °C, as reported. The crystallinity of the  $x = 0.43$  sample increased by heating at 200 °C. Furthermore, the XRD pattern of  $x = 0.43$  heated at 270 °C exhibited specific diffraction peaks attributable to orthorhombic  $\text{Li}_4\text{SnS}_4$  and  $\text{LiI} \cdot \text{H}_2\text{O}$ , especially at 10°–24°. In the case of  $\text{Li}_4\text{SnS}_4$  with LiI, transition to orthorhombic  $\text{Li}_4\text{SnS}_4$  occurred at lower temperature compared with  $\text{Li}_4\text{SnS}_4$ , suggesting that  $\text{Li}_4\text{SnS}_4$  with LiI is thermodynamically metastable. Therefore, preparing them through high temperature synthesis such as conventional solid-phase reaction is challenging.

### Preparation and characterization of solid electrolytes in the $\text{LiI-Li}_3\text{PS}_4\text{-Li}_4\text{SnS}_4$ system

To increase the ionic conductivity of  $x\text{LiI} \cdot (1-x)\text{Li}_4\text{SnS}_4$  solid electrolytes, we considered addition of  $\text{Li}_3\text{PS}_4$ , which shows higher ionic conductivity than  $\text{Li}_4\text{SnS}_4$ . In advance, we determined the best ratio within  $y = 0-0.5$  ( $y\text{Li}_3\text{PS}_4 \cdot (1-y)\text{Li}_4\text{SnS}_4$ ). We reported a systematic study on ionic conductivities and structures of  $y\text{Li}_3\text{PS}_4 \cdot (1-y)\text{Li}_4\text{SnS}_4$ .<sup>33</sup> Fig. S6† shows the XRD patterns and ionic conductivities at 25 and 60 °C of  $y = 0-0.5$  in  $y\text{Li}_4\text{SnS}_4 \cdot (1-y)\text{Li}_3\text{PS}_4$ . As the ratio of  $\text{Li}_3\text{PS}_4$  was increased, the intensity of the diffraction peaks of hexagonal  $\text{Li}_4\text{SnS}_4$  decreased, and ionic conductivity increased. Compared with  $y = 0.4$  and  $0.5$ , both samples showed similar ionic conductivity. We determined  $y = 0.4$  is the best ratio, which is expected to show higher air stability, due to the excess  $\text{Li}_4\text{SnS}_4$  than the  $y = 0.5$  sample.

The  $z\text{LiI} \cdot (1-z)(0.4\text{Li}_3\text{PS}_4 \cdot 0.6\text{Li}_4\text{SnS}_4)$  solid electrolytes were prepared by mechanochemical treatment using  $\text{Li}_2\text{S}$ ,  $\text{SnS}_2$ ,  $\text{P}_2\text{S}_5$ , and LiI as starting materials. Fig. 3a shows the XRD patterns of as-milled solid electrolytes with  $z = 0, 0.37, 0.40, 0.43, 0.45$ , and

**Table 1** Ionic conductivities of  $z\text{LiI} \cdot (1-z)(0.4\text{Li}_3\text{PS}_4 \cdot 0.6\text{Li}_4\text{SnS}_4)$  at 25 °C. “200 °C HT” and “240 °C HT” are indicated after heat treatment at 200 °C and 240 °C, respectively

	LiI : $\text{Li}_3\text{PS}_4$ : $\text{Li}_4\text{SnS}_4$ (mol%)	$\sigma_{25^\circ\text{C}}/\text{S cm}^{-1}$
$z = 0$ (before HT)	0 : 40 : 60	$2.5 \times 10^{-4}$
$z = 0.37$ (before HT)	37 : 25 : 38	$4.5 \times 10^{-4}$
$z = 0.37$ (200 °C HT)	37 : 25 : 38	$4.6 \times 10^{-4}$
$z = 0.37$ (240 °C HT)	37 : 25 : 38	$1.5 \times 10^{-4}$
$z = 0.40$ (before HT)	40 : 24 : 36	$5.0 \times 10^{-4}$
$z = 0.43$ (before HT)	43 : 23 : 34	$5.1 \times 10^{-4}$
$z = 0.50$ (before HT)	50 : 20 : 30	$4.9 \times 10^{-4}$

0.50. The XRD patterns of the samples with LiI exhibited halo patterns and small diffraction peaks derived from hexagonal  $\text{Li}_4\text{SnS}_4$  at 25.4° and 45.1°, suggesting that  $\text{LiI-Li}_3\text{PS}_4\text{-Li}_4\text{SnS}_4$  systems can easily form the amorphous state due to its various components. The  $z = 0.37$  sample consisted of  $0.37\text{LiI} \cdot 0.25\text{Li}_3\text{PS}_4 \cdot 0.38\text{Li}_4\text{SnS}_4$ , and it was prepared with the highest amount of  $\text{Li}_4\text{SnS}_4$  in  $\text{Li}_4\text{SnS}_4$ -based  $z\text{LiI} \cdot (1-z)(0.4\text{Li}_3\text{PS}_4 \cdot 0.6\text{Li}_4\text{SnS}_4)$ . In the  $z$  ratio of more than 0.37, the amount of LiI was higher than that in  $\text{Li}_4\text{SnS}_4$ . In the case of  $x\text{LiI} \cdot (1-x)\text{Li}_4\text{SnS}_4$ , diffraction peaks attributed to residual LiI were observed in the XRD patterns of  $x = 0.45$  and  $0.50$  samples (Fig. 1). In contrast, the diffraction peaks of LiI were not observed in  $z = 0.40-0.50$ , suggesting that excess LiI reacted in  $z\text{LiI} \cdot (1-z)(0.4\text{Li}_3\text{PS}_4 \cdot 0.6\text{Li}_4\text{SnS}_4)$ . DTA measurements were performed for  $z = 0.37$  and  $0.43$  (Fig. 3b). The DTA curves of  $z = 0.37$  and  $0.43$  show large exothermic peaks at 220 and 210 °C, respectively, and two endothermic peaks between 400 and 500 °C. The  $z = 0.37$  sample was heated at 200 and 240 °C, and  $z = 0.43$  was heated at 230 °C. The XRD patterns of  $z = 0.37$  and  $0.43$  after heat treatment are shown in Fig. 3c. The  $z = 0.37$  sample heated at 200 °C has a hexagonal  $\text{Li}_4\text{SnS}_4$  phase with a diffraction peak at 28–29° indicated by an asterisk, which exhibits a high Li/Sn ratio, as mentioned before. Furthermore, the peaks originated from hexagonal  $\text{Li}_4\text{SnS}_4$  did not shift. In contrast,  $x\text{LiI} \cdot (1-x)\text{Li}_4\text{SnS}_4$  showed peak-shifting to the lower angle, as shown in Fig. 1. In addition, in our previous report,  $\text{Li}_4\text{SnS}_4$  with added  $\text{Li}_3\text{PS}_4$  showed slight peak-shifting to a higher angle.<sup>33</sup> These behaviors suggested that  $\text{Li}_4\text{SnS}_4$  with LiI and  $\text{Li}_3\text{PS}_4$  tended not to exhibit peak-shifting. Therefore,  $z = 0.37$  heated at 200 °C enhanced the Li/Sn ratio compared with  $\text{Li}_4\text{SnS}_4$  without decomposition reactions. In contrast, after heat treatment at 240 °C, diffraction peaks of  $\text{LiI} \cdot \text{H}_2\text{O}$  were observed, suggesting that the exothermic peak at ~220 °C in the DSC curve corresponded to the decomposition reaction. In the  $z = 0.43$  sample, after heat treatment at 230 °C, the intensity of the peaks attributable to  $\text{LiI} \cdot \text{H}_2\text{O}$  increased even though it was heated at a lower temperature, indicating that the decomposition reaction could easily proceed with the large amount of LiI.

Table 1 shows the ionic conductivities of the  $z = 0, 0.37, 0.40, 0.43$ , and  $0.50$  samples in  $z\text{LiI} \cdot (1-z)(0.4\text{Li}_3\text{PS}_4 \cdot 0.6\text{Li}_4\text{SnS}_4)$  at room temperature (25 °C) before and after heat treatment. The ionic conductivities of the LiI-added samples of  $z = 0.37, 0.40, 0.43$ , and  $0.50$  before heat treatment increased up to  $ca. 5 \times 10^{-4} \text{ S cm}^{-1}$  compared with those of  $z = 0$ . The ionic

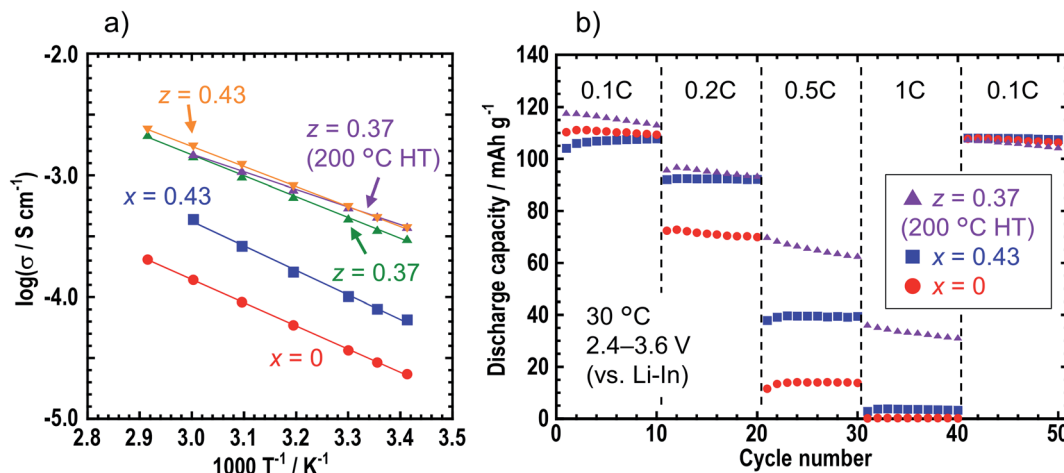

Fig. 4 (a) Temperature dependence of ionic conductivities of  $x = 0$  and  $x = 0.43$  samples in  $x\text{LiI} \cdot (1 - x)\text{Li}_4\text{SnS}_4$  and  $z = 0.37$  (before and after the heat treatment at 200 °C) and  $z = 0.43$  in  $z\text{LiI} \cdot (1 - z)(0.4\text{Li}_3\text{PS}_4 \cdot 0.6\text{Li}_4\text{SnS}_4)$ . (b) Discharge capacities of the all-solid-state cells where  $x = 0$ ,  $x = 0.43$  and  $z = 0.37$  (heating at 200 °C) at rates of 0.1, 0.2, 0.5, and 1C.

conductivity of  $z = 0.37$  heated at 200 °C was not different from that of the sample before heat treatment, while that of  $z = 0.37$  heated at 240 °C decreased to  $1.5 \times 10^{-4} \text{ S cm}^{-1}$  because of decomposition. Fig. 4 shows the temperature dependence of the ionic conductivities of  $x = 0$  and 0.43 in  $x\text{LiI} \cdot (1 - x)\text{Li}_4\text{SnS}_4$  and  $z = 0.37$  (before and after the heat treatment at 200 °C) and 0.43 in  $z\text{LiI} \cdot (1 - z)(0.4\text{Li}_3\text{PS}_4 \cdot 0.6\text{Li}_4\text{SnS}_4)$ . These ionic conductivities obeyed Arrhenius law of  $\sigma = \sigma_0 \exp(-E_a/RT)$ , where  $\sigma_0$  is a pre-exponential factor,  $E_a$  is an activation energy,  $R$  is the gas constant, and  $T$  is temperature. The activation energies were calculated by slopes of the Arrhenius plots. The ionic conductivities at 30 °C and the activation energies of these samples are listed in Table S6† with the data of  $0.4\text{LiI} \cdot 0.6\text{Li}_4\text{SnS}_4$  glass.<sup>12</sup> The activation energies of the  $\text{LiI}-\text{Li}_3\text{PS}_4-\text{Li}_4\text{SnS}_4$  systems before and after heat treatment were 32–33 and 28  $\text{kJ mol}^{-1}$ , respectively. The  $z = 0.37$  sample heated at 200 °C showed the lowest activation energy, whereas the  $\text{LiI}-\text{Li}_4\text{SnS}_4$  systems showed higher

activation energies of nearly 40  $\text{kJ mol}^{-1}$ . Furthermore,  $z = 0.37$  and 0.43 samples exhibited higher ionic conductivities at 30 °C ( $5.5 \times 10^{-4} \text{ S cm}^{-1}$ ) than  $0.4\text{LiI} \cdot 0.6\text{Li}_4\text{SnS}_4$  glass prepared by the liquid-phase synthesis.<sup>12</sup> Therefore,  $z\text{LiI} \cdot (1 - z)(0.4\text{Li}_3\text{PS}_4 \cdot 0.6\text{Li}_4\text{SnS}_4)$  solid electrolytes prepared by mechanochemical treatment exhibited higher ionic conductivity and lower activation energy than those reported for  $\text{LiI}$ -added  $\text{Li}_4\text{SnS}_4$ -based solid electrolytes.

To investigate the electrochemical stability windows of the  $\text{Li}_4\text{SnS}_4$ -based solid electrolytes, cyclic voltammetry was conducted for the  $\text{Li}/\text{solid electrolytes}/\text{SUS}$  asymmetric cells using  $\text{Li}_4\text{SnS}_4$  ( $x = 0$ ),  $0.43\text{LiI} \cdot 0.57\text{Li}_4\text{SnS}_4$  ( $x = 0.43$  in  $x\text{LiI} \cdot (1 - x)\text{Li}_4\text{SnS}_4$ ), and  $0.37\text{LiI} \cdot 0.25\text{Li}_3\text{PS}_4 \cdot 0.38\text{Li}_4\text{SnS}_4$  with heating at 200 °C ( $z = 0.37$  in  $z\text{LiI} \cdot (1 - z)(0.4\text{Li}_3\text{PS}_4 \cdot 0.6\text{Li}_4\text{SnS}_4)$ ) as solid electrolyte layers (Fig. S7†). The cyclic voltammograms of all cells exhibited several peaks between  $-0.5$  and 3 V (vs.  $\text{Li}^+/\text{Li}$ ), in addition to a pair of reduction and oxidation peaks close to 0 V,

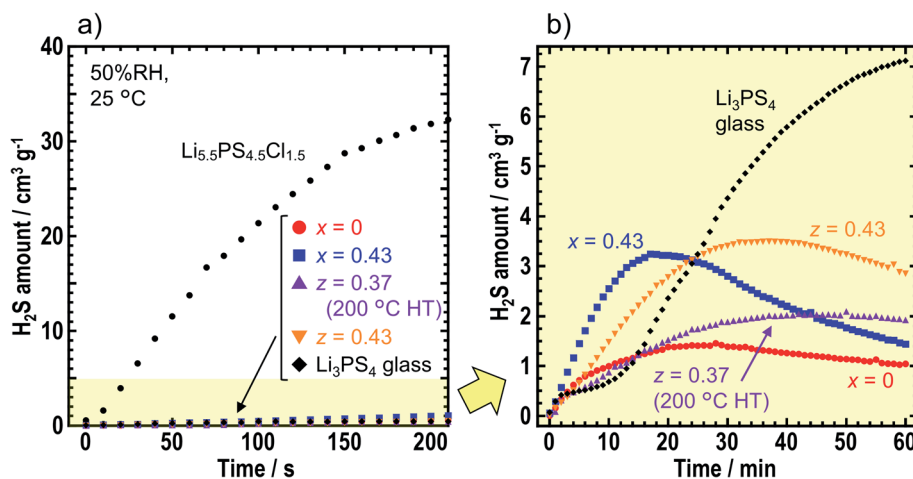

Fig. 5 (a)  $\text{H}_2\text{S}$  generation when the solid electrolyte powder was sealed in a desiccator filled with air (50% RH) at 25 °C for 210 s. The following samples were examined:  $\text{Li}_{5.5}\text{PS}_{4.5}\text{Cl}_{1.5}$ ,  $\text{Li}_3\text{PS}_4$  glass,  $x = 0$  and  $x = 0.43$  in  $x\text{LiI} \cdot (1 - x)\text{Li}_4\text{SnS}_4$  and  $z = 0.37$  (heating at 200 °C) and  $z = 0.43$  in  $z\text{LiI} \cdot (1 - z)(0.4\text{Li}_3\text{PS}_4 \cdot 0.6\text{Li}_4\text{SnS}_4)$ . The amount of solid electrolyte employed was 2 mg for  $\text{Li}_{5.5}\text{PS}_{4.5}\text{Cl}_{1.5}$  and 50 mg for all others. (b)  $\text{H}_2\text{S}$  generation from the various solid electrolytes with the exception of  $\text{Li}_{5.5}\text{PS}_{4.5}\text{Cl}_{1.5}$ . The measurement time was 60 min.

which corresponded to lithium deposition and reduction. This indicates that  $\text{Li}_4\text{SnS}_4$ -based solid electrolytes undergo decomposition between  $-0.5$  and  $3$  V (vs.  $\text{Li}^+/\text{Li}$ ). However, in Fig. S7,† no peaks were observed between  $3$  and  $5$  V, thereby suggesting that the  $\text{Li}_4\text{SnS}_4$ -based solid electrolytes are stable at high voltages and can be used in a composite positive electrode layer. Moreover, we note that in our previous report,  $\text{Li}_4\text{SnS}_4$  was found to exhibit a high thermal stability to oxide positive electrodes.<sup>34</sup>

Charge–discharge tests were carried out for the all-solid-state cells containing NMC composite positive electrodes with  $x = 0$ ,  $x = 0.43$ , and  $z = 0.37$  (heated at  $200^\circ\text{C}$ ) solid electrolytes. Fig. 4b shows the discharge capacities of the cells at  $0.1$ ,  $0.2$ ,  $0.5$ , and  $1\text{C}$ . In the case where the  $z = 0.37$  sample was used in the composite positive electrode, the rate performance improved compared with those obtained for the  $x = 0$  and  $0.43$  samples because of the higher ionic conductivity of the  $z = 0.37$  sample.

### Air stability tests of the prepared solid electrolytes

To compare air stabilities of the prepared solid electrolytes,  $\text{H}_2\text{S}$  gas generation was monitored when the solid electrolyte powder was placed in the desiccator filled with air ( $50\%$  RH). Fig. 5 shows the amount of  $\text{H}_2\text{S}$  gas generated by  $x = 0$  and  $x = 0.43$  in  $x\text{LiI} \cdot (1 - x)\text{Li}_4\text{SnS}_4$ , and  $z = 0.37$  (after the heat treatment at  $200^\circ\text{C}$ ) and  $z = 0.43$  in  $z\text{LiI} \cdot (1 - z)(0.4\text{Li}_3\text{PS}_4 \cdot 0.6\text{Li}_4\text{SnS}_4)$ . We compared  $\text{Li}_3\text{PS}_4$  glass and an argyrodite-type solid electrolyte of  $\text{Li}_{5.5}\text{PS}_{4.5}\text{Cl}_{1.5}$ . In Fig. 5a,  $2\text{ mg}$  of  $\text{Li}_{5.5}\text{PS}_{4.5}\text{Cl}_{1.5}$  emitted the largest amount of  $\text{H}_2\text{S}$  in  $210\text{ s}$  although the amount of  $\text{Li}_{5.5}\text{PS}_{4.5}\text{Cl}_{1.5}$  was  $1/25$  of that other solid electrolytes. Therefore, argyrodite-type solid electrolytes show extremely low air stability compared with  $\text{Li}_4\text{SnS}_4$ -based solid electrolytes and  $\text{Li}_3\text{PS}_4$  glass.

Fig. 5b shows the amount of  $\text{H}_2\text{S}$  gas generated from the  $\text{Li}_4\text{SnS}_4$ -based solid electrolytes and  $\text{Li}_3\text{PS}_4$  glass in  $1\text{ h}$ . Note that the range of  $\text{H}_2\text{S}$  amount changed from  $0\text{--}40$  to  $0\text{--}5\text{ cm}^3\text{ g}^{-1}$ . With an exposure time of  $60\text{ min}$ ,  $\text{Li}_3\text{PS}_4$  glass emitted the highest amount of  $\text{H}_2\text{S}$  gas over the various solid electrolytes, thereby indicating that hexagonal  $\text{Li}_4\text{SnS}_4$ -based solid electrolytes exhibited higher air stabilities than  $\text{Li}_3\text{PS}_4$  glass. The  $\text{Li}_4\text{SnS}_4$  with  $\text{LiI}$  tended to emit higher amount of  $\text{H}_2\text{S}$  gas than  $\text{Li}_4\text{SnS}_4$ . For the first  $10\text{--}15\text{ min}$ , the speed of  $\text{H}_2\text{S}$  gas generation was higher for  $x = 0.43$  and  $z = 0.43$ , suggesting that higher amount of  $\text{LiI}$  promoted  $\text{H}_2\text{S}$  gas generation. As  $\text{LiI}$  can easily react with moisture, solid electrolytes prepared from high amount of  $\text{LiI}$  may react with moisture easily. Next, the concentration of  $\text{H}_2\text{S}$  decreased. This phenomenon may be attributed to the lower speed of  $\text{H}_2\text{S}$  gas emission than the speed of oxidation of  $\text{H}_2\text{S}$  gas in air and/or dissolution of  $\text{H}_2\text{S}$  gas in moisture.<sup>35,36</sup> The maximum values of  $\text{H}_2\text{S}$  emitted from  $x = 0$  and  $z = 0.37$  ( $200^\circ\text{C}$  HT) were  $1.5$  and  $2.1\text{ cm}^3\text{ g}^{-1}$ , respectively. Calpa *et al.* reported that  $\text{Li}_4\text{PS}_4\text{I}$  showed higher air stability than  $\text{Li}_3\text{PS}_4$  due to the formation of  $\text{LiI} \cdot \text{H}_2\text{O}$ , which acted as a barrier between  $\text{PS}_4^{3-}$  units and  $\text{H}_2\text{S}$ .<sup>37</sup> In the present study on  $\text{Li}_4\text{SnS}_4$  with  $\text{LiI}$ ,  $\text{LiI} \cdot 3\text{H}_2\text{O}$  (ICSD #759794) was formed after air exposure irrespective of the presence of  $\text{Li}_3\text{PS}_4$  (Fig. S8†). As a result, although  $\text{Li}_3\text{PS}_4$  showed lower air stability

than  $\text{Li}_4\text{SnS}_4$ ,<sup>14</sup> addition of  $\text{LiI}$  suppressed the decomposition of  $\text{Li}_3\text{PS}_4$  in  $\text{LiI}\text{--}\text{Li}_3\text{PS}_4\text{--}\text{Li}_4\text{SnS}_4$  type solid electrolytes. Therefore,  $z = 0.37$  in  $z\text{LiI} \cdot (1 - z)(0.6\text{Li}_4\text{SnS}_4 \cdot 0.4\text{Li}_3\text{PS}_4)$  heated at  $200^\circ\text{C}$  showed a higher ionic conductivity of  $5.5 \times 10^{-4}\text{ S cm}^{-1}$  at  $30^\circ\text{C}$  and a high air stability similar to  $\text{Li}_4\text{SnS}_4$ . Fig. S8† shows that diffraction peaks, attributed to  $\text{SnS}_2$ , were observed at  $15.0^\circ$  and  $32.2^\circ$  in the XRD patterns after air exposure, suggesting partial decomposition of solid electrolytes. In this study, solid electrolyte powder was used for air stability measurements. Note that powdered sample was easier to be influenced by moisture than pelletized samples because of the availability of larger surface areas. Further investigation is required to study the decomposition mechanism and make guidelines for suppression of  $\text{H}_2\text{S}$  gas emission.

## Conclusions

Hexagonal  $\text{Li}_4\text{SnS}_4$ -based solid electrolytes with  $\text{LiI}$  and/or  $\text{Li}_3\text{PS}_4$  were prepared by mechanochemical treatment to enhance the ionic conductivity of hexagonal  $\text{Li}_4\text{SnS}_4$ . The sample with  $x = 0.43$  in  $x\text{LiI} \cdot (1 - x)\text{Li}_4\text{SnS}_4$  showed higher ionic conductivity of  $1.6 \times 10^{-4}\text{ S cm}^{-1}$  at room temperature than the sample with  $x = 0$  ( $4.5 \times 10^{-5}\text{ S cm}^{-1}$ ). We considered that higher ionic conductivities of  $\text{Li}_4\text{SnS}_4$  with  $\text{LiI}$  resulted from the higher amount of  $\text{Li}$  carrier due to the increase in the  $\text{Li}/\text{Sn}$  ratio and the expansion of conduction paths of  $\text{Li}^+$  ion due to the introduction of  $\text{I}^-$ , which has a large ionic radius. PDF analysis and Raman spectroscopy suggested that  $\text{I}^-$  ions existed between  $\text{SnS}_4^{4-}$  units. As-milled samples of  $\text{Li}_4\text{SnS}_4$  with  $\text{LiI}$  and  $\text{Li}_3\text{PS}_4$  formed the amorphous state. The sample with  $z = 0.37$  in  $z\text{LiI} \cdot (1 - z)(0.4\text{Li}_3\text{PS}_4 \cdot 0.6\text{Li}_4\text{SnS}_4)$ , after heat-treatment at  $200^\circ\text{C}$ , exhibited ionic conductivity of  $5.5 \times 10^{-4}\text{ S cm}^{-1}$  at  $30^\circ\text{C}$  with an activation energy of  $28\text{ kJ mol}^{-1}$ . It showed the highest ionic conductivity in hexagonal  $\text{Li}_4\text{SnS}_4$ -based solid electrolytes. All-solid-state batteries using NMC composite positive electrodes with  $z = 0.37$  (heated at  $200^\circ\text{C}$ ) sample showed the highest rate performance compared to the samples where  $x = 0$  and  $x = 0.43$ . Furthermore, the sample with  $z = 0.37$  heated at  $200^\circ\text{C}$  showed similar air stability to  $\text{Li}_4\text{SnS}_4$ . Formation of  $\text{LiI} \cdot 3\text{H}_2\text{O}$  prevents further decomposition of  $\text{Li}_3\text{PS}_4$  in  $\text{LiI}\text{--}\text{Li}_3\text{PS}_4\text{--}\text{Li}_4\text{SnS}_4$  solid electrolytes. We believe that hexagonal  $\text{Li}_4\text{SnS}_4$ -based solid electrolytes with additives will keep being developed in the future because of their high ionic conductivity and air stability. Our results provide a new strategy for increasing the ionic conductivity of hexagonal  $\text{Li}_4\text{SnS}_4$  without decreasing the air stability by mechanochemical treatment. Future work in this area will focus on the addition of other components, such as oxide materials, to improve the electrolyte stability toward lithium.

## Author contributions

M. O. developed the idea and conducted experiments. K. K. and H. K. supervised the work. All authors discussed the results and prepared the manuscript. All authors have given approval to the final version of the manuscript.

## Conflicts of interest

There are no conflicts to declare.

## Acknowledgements

This work was supported by JSPS KAKENHI Grant number JP20K22558. The PDF analysis was supported by Masatsugu Yoshimoto and Hikari Takahara (Rigaku Corp.).
