## Investigation on the upconversion luminescence and ratiometric thermal sensing of $\text{SrWO}_4:\text{Yb}^{3+}/\text{RE}^{3+}$ ( $\text{RE} = \text{Ho}/\text{Er}$ ) phosphors

 Hang Liu, Xiukai Jian, Mingtai Liu, Kailin Wang, Guangyao Bai and Yuhong Zhang \*

$\text{SrWO}_4$  phosphors doped with  $\text{Ho}^{3+}/\text{Er}^{3+}/\text{Yb}^{3+}$  are successfully prepared by a high temperature solid-state reaction method. The upconversion (UC) luminescence properties of all the samples have been investigated under 980 nm excitation. Strong green emissions are obtained in the  $\text{SrWO}_4:\text{Yb}^{3+}/\text{Ho}^{3+}$  and  $\text{SrWO}_4:\text{Yb}^{3+}/\text{Er}^{3+}$  samples with the naked eyes. In a temperature range going from 303 K to 573 K, the UC emission spectra of the phosphors have been measured. Then the temperature sensing properties also have been discussed *via* fluorescence intensity ratio (FIR) technology. For the  $\text{SrWO}_4:\text{Yb}^{3+}/\text{Ho}^{3+}$  phosphor, the FIR technologies based on thermal coupling levels (TCLs) $(^5\text{F}_4, ^5\text{F}_5)$  and non-thermal coupling levels (non-TCLs) $(^5\text{S}_2, ^5\text{F}_4, ^5\text{F}_5)$  are used for investigating the sensitivity. The results show that the maximum absolute sensitivity reaches  $0.0158 \text{ K}^{-1}$  with non-TCLs. As for  $\text{Yb}^{3+}/\text{Er}^{3+}$  codoped  $\text{SrWO}_4$  phosphor, the maximum absolute sensitivity reaches  $0.013 \text{ K}^{-1}$  with TCLs $(^2\text{H}_{11/2}, ^4\text{S}_{5/2})$  at a temperature of 513 K. These significant results demonstrate that the  $\text{SrWO}_4:\text{Ho}^{3+}/\text{Er}^{3+}/\text{Yb}^{3+}$  phosphors are robust for optical temperature sensors.

### 1. Introduction

As the basic parameter of thermodynamics, temperature measurement plays a vital role in scientific research, industrial production and medicine.<sup>1</sup> In recent years, much attention has been paid to non-contact temperature sensors based on rare earth (RE) ion activated luminescent materials.<sup>2</sup> Some UC luminescent materials with doping of  $\text{RE}^{3+}$  ions have been studied for temperature sensors.<sup>3–7</sup> The FIR technology based on the measurement of the temperature-dependent FIR from two excited state energy levels of activators represents an accurate temperature measuring method, because the FIR from the thermally coupled levels (TCLs) of RE ions is independent of the excitation intensity fluctuations, external disturbance and spectrum losses. Thus, reasonable measurement accuracy and sensitivity could be obtained with this method. The variation of FIR is generally caused by a thermally induced population redistribution among the TCLs. And some RE ions have already been explored for designing FIR thermometry, such as  $\text{Er}^{3+}$ ,  $\text{Tm}^{3+}$ ,  $\text{Ho}^{3+}$  *et al.*<sup>8–13</sup> The sensitivity is an important role of a temperature sensing device. The absolute sensitivity is defined as the rate of change of FIR with change in temperature relative to FIR. Basically, a larger energy gap between the TCLs benefits the enhancement of sensitivity. However, the largest energy mismatches between those TCLs cannot exceed  $2000 \text{ cm}^{-1}$ , so it is difficult for the further improvement of sensitivity. There is an urgent need to design a new temperature

measurement method to obtain high detecting sensitivity. Recently, a new kind of strategy has been proposed to solve the above drawback, which is based on FIR between the non-TCLs of the activators. The FIR derived from non-TCLs is also related to temperature. Compared with the FIR technique based on the TCLs, the FIR technique based on the non-TCLs is no longer limited by the energy gap. The  $\text{Er}^{3+}$  and  $\text{Ho}^{3+}$  ions also have non-TCLs pairs in addition to TCLs. So further investigation on temperature sensing properties of  $\text{Er}^{3+}$  and  $\text{Ho}^{3+}$  ions based on the FIR technology (TCLs and non-TCLs) is necessary.

Besides activators, temperature sensing properties of UC luminescent materials are also decided by host material. Among various hosts, tungstates have obtained much attention because of their brilliant physical and chemical stability, low phonon threshold energy, and high density.<sup>14</sup> The  $\text{Ln}^{3+}$  ions also have high doped concentration in tungstates host. So the activators can emit intense and stable fluoresce even at high temperature.<sup>15</sup>  $\text{SrWO}_4$  belongs to a body-centered tetragonal system with scheelite crystal structure where  $\text{WO}_4^{2-}$  molecular ions are loosely bound to  $\text{Sr}^{2+}$  cations. It has been reported that  $\text{SrWO}_4$  is an ideal host for optical temperature sensing materials. Recently, the temperature sensing properties of  $\text{Ln}^{3+}$  doped tungstates also have been studied. Pandey *et al.* report that the  $\text{Er}^{3+}-\text{Yb}^{3+}$  co-doped  $\text{SrWO}_4$  phosphor is a good optical temperature sensing material, and its maximum absolute sensitivity reaches  $0.01498 \text{ K}^{-1}$ .<sup>16</sup> The high sensitivity of  $\text{Tm}^{3+}/\text{Yb}^{3+}$  co-doped  $\text{SrWO}_4$  phosphor for optical thermometry is synthesized by Song *et al.*, and when the temperature is 323 K, the absolute sensitivity reaches a maximum of  $0.00617 \text{ K}^{-1}$ .<sup>17</sup> For  $\text{Sm}^{3+}$  doped  $\text{SrWO}_4$  phosphor and  $\text{Nd}^{3+}/\text{Yb}^{3+}$  co-doped

School of Electrical and Computer Engineering, Jilin Jianzhu University, Changchun 130118, China. E-mail: zhangyuhong@jlu.edu.cn; liuhang76@163.com

$\text{SrWO}_4$  phosphor, they also have good temperature sensing performance.<sup>18,19</sup> Note that, the  $\text{SrWO}_4$  material is more suitable to be a UC fluorescence host for designing optical temperature sensor. However, as far as we know, the  $\text{SrWO}_4:\text{Yb}^{3+}/\text{Ho}^{3+}$  phosphor for optical thermometry has not been investigated. There are even fewer reports on its optical thermometry using FIR technique based on the non-TCLs.

In this paper, the  $\text{SrWO}_4:\text{Yb}^{3+}/\text{RE}^{3+}$  ( $\text{RE} = \text{Er, Ho}$ ) phosphors are synthesized by a high temperature solid state reaction. The UC luminescence performances and temperature sensing properties are investigated under 980 nm excitation. The experimental results illustrate that the temperature sensitivity of our phosphors are better than the most reported  $\text{Ho}^{3+}(\text{Er}^{3+})$  doped materials. The  $\text{SrWO}_4$  doping  $\text{Ho}^{3+}(\text{Er}^{3+})$  ions materials are optical temperature sensing material with good application value.

## 2. Experimental

### 2.1 Synthesis of the phosphor

The samples are designed according to the molar composition of  $\text{Sr}_{1-x-0.01}\text{Yb}_x\text{Ho}_{0.01}\text{WO}_4$  ( $x = 0, 1\%, 2\%, 3\%, 4\%, 6\%, 10\%$ ) and  $\text{Sr}_{1-y-0.01}\text{Yb}_y\text{Er}_{0.01}\text{WO}_4$  ( $y = 0, 1\%, 2\%, 3\%, 4\%$ ), and synthesized by solid-state reaction method. High-purity  $\text{SrCO}_3$  (99%),  $\text{WO}_3$  (99.8%),  $\text{Yb}_2\text{O}_3$  (99.99%),  $\text{Ho}_2\text{O}_3$  (99.99%) and  $\text{Er}_2\text{O}_3$  (99.99%) are purchased from Aladdin Chemical Reagent Co. Ltd (China). The raw materials are weighed by molar ratio and mixed together. The mixtures thoroughly are ground in a mortar of agate for 60 minutes. The ground mixture is transferred to a crucible ceramics and then heated it in a muffle furnace. First, the temperature rises to 900 °C by 10 °C min<sup>-1</sup>. The samples are kept at 900 °C for 4 h. Next, temperature is increased by 5 °C min<sup>-1</sup> to 1100 °C and kept for 6 h. Finally the  $\text{SrWO}_4:\text{Ho}^{3+}/\text{Yb}^{3+}$  and  $\text{SrWO}_4:\text{Er}^{3+}/\text{Yb}^{3+}$  phosphors are obtained.

### 2.2 Measurement and characterization

The structural formation of the phosphors has been measured using an X-ray diffraction (Rigaku D/Max-2500) in the range of 15° to 80° (2θ), and its radiation source is Cu Kα ray of  $\lambda = 0.15406$  nm. For morphology and size of the phosphors, the

field emission scanning electron microscope (FE-SEM, JEOL JEM-6700F) is used to perform. The UC emission spectra are recorded using the Zolix Omni-λ500 spectrometer under a 980 nm laser (MDL-III-980-2W, China) excitation. The samples are heated using an Orient KOJI TAP-02 high temperature thermometer, among a temperature range of 303 to 573 K, with a temperature control accuracy of 0.1 °C.

## 3. Result and discussion

### 3.1 Structural characterization

Fig. 1(a) shows the XRD patterns of the  $\text{SrWO}_4:\text{Ho}^{3+}/\text{Yb}^{3+}$  phosphors. It can be seen that the diffraction peaks of the samples are very consistent with the standard card of  $\text{SrWO}_4$  (JCPDS no. 08-0490). The sharp and strong diffraction peaks show that the synthesized samples are crystallized well. It also means that  $\text{Sr}^{2+}$  in the  $\text{SrWO}_4$  lattice is substituted by  $\text{Ho}^{3+}$  and  $\text{Yb}^{3+}$  ions. The XRD patterns of the  $\text{SrWO}_4:\text{Er}^{3+}/\text{Yb}^{3+}$  samples are shown in Fig. 1(b). The main diffraction peaks of samples are also consistent with the standard card of  $\text{SrWO}_4$  (JCPDS no. 08-0490). But an extra weak peak at 29.3° appears in  $\text{SrWO}_4:1\%\text{Er}^{3+}, x\%\text{Yb}^{3+}$  ( $x = 2, 3, 4$ ) samples, which may be induced by the minor unreacted component of  $\text{Yb}_2\text{O}_3$ . Once the concentration of the  $\text{Yb}^{3+}$  ions is over 2%, a part of the  $\text{Yb}^{3+}$  ions will not be added in the lattice. In addition, the peak at 30° moves to a high angle direction with the concentration of  $\text{Yb}^{3+}$  ions increasing (see the illustration in Fig. 1(b)), which is attributed to the shrinkage of the crystal lattice caused by the doped  $\text{Er}^{3+}$  and  $\text{Yb}^{3+}$  ions substituting the  $\text{Sr}^{2+}$  sites. The ionic radius of  $\text{Er}^{3+}$ ,  $\text{Yb}^{3+}$  and  $\text{Sr}^{2+}(\text{Er}^{3+}: 0.89$  Å,  $\text{Yb}^{3+}: 0.86$  Å and  $\text{Sr}^{2+}: 1.12$  Å) are different, so the crystal lattice will produce deformation. The SEM images of  $\text{SrWO}_4:\text{Ho}^{3+}(\text{Er}^{3+})/\text{Yb}^{3+}$  phosphor are shown in Fig. 2. It indicates that the size of the prepared phosphor is almost uniform.

### 3.2 Upconversion emission properties

Fig. 3(a) shows the UC emission spectrum of  $\text{SrWO}_4:1\%\text{Ho}^{3+}/2\%\text{Yb}^{3+}$  phosphor from 500 to 800 nm under 980 nm excitation. Three characteristic emission bands are presented that the strong green emission (~540 nm) belongs to the radiative

Fig. 1 XRD patterns of  $\text{SrWO}_4$ : (a)  $1\%\text{Ho}^{3+}/x\%\text{Yb}^{3+}$  ( $x = 0, 1, 2, 3, 4, 6, 10$ ) phosphors. (b)  $1\%\text{Er}^{3+}/x\%\text{Yb}^{3+}$  ( $x = 0, 1, 2, 3, 4$ ) phosphors.

Fig. 2 SEM images of  $\text{SrWO}_4$ : (a)  $1\% \text{Ho}^{3+}/2\% \text{Yb}^{3+}$  phosphor. (b)  $1\% \text{Er}^{3+}/1\% \text{Yb}^{3+}$  phosphor.

transition from the  $^5\text{S}_2/{}^5\text{F}_4$  to  ${}^5\text{I}_8$ , the red emission ( $\sim 663$  nm) belongs to the radiative transition from  ${}^5\text{F}_5$  to  ${}^5\text{I}_8$  and the weak near infrared emission ( $\sim 756$  nm) corresponds to  ${}^5\text{F}_4 \rightarrow {}^5\text{I}_7$  energy level transition of  $\text{Ho}^{3+}$  ions. Fig. 3(b) shows the UC emission spectra of  $\text{SrWO}_4:1\% \text{Ho}^{3+}/x\% \text{Yb}^{3+}$  ( $x = 0, 1, 2, 3, 4, 6, 10$ ). It is seen that, the intensities of all the UC emission peaks reach maximum values at  $x = 2$ . But they decrease if the  $\text{Yb}^{3+}$  concentration is further increased up to 2%. The  $\text{Yb}^{3+}$  ion is a high-efficiency sensitizer for  $\text{Ho}^{3+}$  ion because it has larger absorption cross-sectional area at the near infrared. With increasing the  $\text{Yb}^{3+}$  ions concentration to 2%, the energy transfer process from  $\text{Yb}^{3+}$  to  $\text{Ho}^{3+}$  can be enhanced, resulting in higher UC emission intensity. However, with the further enhancement of the  $\text{Yb}^{3+}$  concentrations, the distance between the doping ions decreases with the increase of  $\text{Yb}^{3+}$  concentration. It induces more intense interaction among adjacent  $\text{Yb}^{3+}$  ions, which cause concentration quenching.<sup>20</sup>

In order to explicate the possible UC emission process of the  $\text{SrWO}_4:\text{Ho}^{3+}/\text{Yb}^{3+}$  sample, the dependence relation of the UC

emission intensity *via* pump power is measured. The relationship between UC emission intensity and pumping power can be described by the following eqn (1):<sup>21</sup>

$$I \propto P^n \quad (1)$$

where  $I$  is the UC emission intensity,  $P$  is the pumping power and  $n$  is the photon numbers which correspond to populate the upper emitting levels. Fig. 3(c) shows the log–log plot of intensity *versus* pump power and the slopes of the fitted lines of  $\text{SrWO}_4:1\% \text{Ho}^{3+}/2\% \text{Yb}^{3+}$  sample. It can be seen that  $n$  values are 1.21, 1.24 and 2.27 for green ( $\sim 540$  nm), red ( $\sim 663$  nm), and near-infrared ( $\sim 756$  nm) emissions. It indicates that these UC emission processes are related to the two-photon processes. The energy level diagrams of  $\text{Ho}^{3+}/\text{Yb}^{3+}$  ions and possible UC emission processes are shown in Fig. 3(d).

Under 980 nm excitation, the  $\text{Yb}^{3+}$  ion are excited from the ground state  ${}^2\text{F}_{7/2}$  to the excited state  ${}^2\text{F}_{5/2}$  by ground state absorption (GSA) process.  $\text{Ho}^{3+}$  ions are excited to the excited state levels mainly through the energy transfer (ET) process from  $\text{Yb}^{3+}$  to  $\text{Ho}^{3+}$ . Through ET1 ( ${}^2\text{F}_{5/2}(\text{Yb}^{3+}) + {}^5\text{I}_8(\text{Ho}^{3+}) \rightarrow {}^2\text{F}_{7/2}(\text{Yb}^{3+}) + {}^5\text{I}_6(\text{Ho}^{3+})$ ), the  $\text{Ho}^{3+}$  ions are excited from the  ${}^5\text{I}_8$  to the  ${}^5\text{I}_6$  state.<sup>22</sup> Some  $\text{Ho}^{3+}$  ions at  ${}^5\text{I}_6$  state can nonradiatively (NR) relax to  ${}^5\text{I}_7$  state, and then populating the  ${}^5\text{F}_5$  state by excited state absorption (ESA) from  ${}^5\text{I}_7$  to  ${}^5\text{F}_5$ .  $\text{Ho}^{3+}$  ions at  ${}^5\text{I}_6$  state can continue to be excited into the  ${}^5\text{S}_2$ ,  ${}^5\text{F}_4$  coupling state by ET2 ( ${}^2\text{F}_{5/2}(\text{Yb}^{3+}) + {}^5\text{I}_6(\text{Ho}^{3+}) \rightarrow {}^2\text{F}_{7/2}(\text{Yb}^{3+}) + {}^5\text{S}_2, {}^5\text{F}_4(\text{Ho}^{3+})$ ). Subsequently, the  $\text{Ho}^{3+}$  ions at the  ${}^5\text{S}_2$ ,  ${}^5\text{F}_4$  coupling state will relax to the  ${}^5\text{F}_5$  state by NR relaxation, and then a part of the  $\text{Ho}^{3+}$  ions at the  ${}^5\text{F}_5$  state are transferred to the  ${}^5\text{I}_8$  state, concurrently red light of 663 nm is emitted. The  ${}^5\text{S}_2$ ,  ${}^5\text{F}_4$  coupling state relax to the  ${}^5\text{I}_8$  and  ${}^5\text{I}_7$  states, resulting in high

UC emission spectra of SrWO<sub>4</sub>:1%Er<sup>3+</sup>/x%Yb<sup>3+</sup> (x = 0, 1, 2, 3, 4). (c). Log-log relationship between pump power and UC emission intensity of SrWO<sub>4</sub>:1%Er<sup>3+</sup>/1%Yb<sup>3+</sup> phosphor. (d). The energy level diagrams of Er<sup>3+</sup>/Yb<sup>3+</sup> ions and possible UC emission processes.

intensity green light (~540 nm) and low intensity red light (~756 nm), respectively.

The UC emission spectrum of SrWO<sub>4</sub>:1%Er<sup>3+</sup>/1%Yb<sup>3+</sup> phosphor is shown in Fig. 4(a). Two UC emission bands are exhibited, the strong green and the weak red emission, which can be attributed to the radiative transitions from <sup>2</sup>H<sub>11/2</sub>/<sup>4</sup>S<sub>3/2</sub> to <sup>4</sup>I<sub>15/2</sub> and the <sup>4</sup>I<sub>9/2</sub> → <sup>4</sup>I<sub>15/2</sub> of the Er<sup>3+</sup> ions, respectively. Fig. 4(b) shows the UC emission spectra of SrWO<sub>4</sub>:1%Er<sup>3+</sup>/x%Yb<sup>3+</sup> (x = 0, 1, 2, 3, 4). It can be found that the intensities of two emission bands first increase and then decrease with increasing Yb<sup>3+</sup> concentrations, and reach a maximum at x = 1. Once the concentration of Yb<sup>3+</sup> is over 1%, the UC emission intensities rapidly decline. This is mainly attributed to that the energy transfer efficiency from Yb<sup>3+</sup> to Er<sup>3+</sup> ion decrease because the limit of the Yb<sup>3+</sup> that can be stabilized into the matrix. As demonstrated by the extra peaks in the XRD patterns, when the concentration of the Yb<sup>3+</sup> ions is over 2%, a part of the Yb<sup>3+</sup> ions will not be added in the lattice.

The dependence relationship of the UC emission intensities of SrWO<sub>4</sub>:Er<sup>3+</sup>/Yb<sup>3+</sup> on pump power are shown in Fig. 4(c). For the emission ~528 nm, 550 nm and 654 nm, the slopes of the fitting experiment data are 1.70, 1.16 and 1.13, which is near 2. It indicates that all emission processes are related to the two-photon processes. Fig. 4(d) shows the energy level diagrams and possible UC emission processes of Er<sup>3+</sup> and Yb<sup>3+</sup> ion. Under 980 nm laser excitation, Yb<sup>3+</sup> ions are excited from the ground state <sup>2</sup>F<sub>7/2</sub> to the excited state <sup>2</sup>F<sub>5/2</sub> by GSA process. The Er<sup>3+</sup> ions are excited to the <sup>4</sup>I<sub>11/2</sub> state from the ground state through the

ET1 (<sup>2</sup>F<sub>5/2</sub> (Yb<sup>3+</sup>) + <sup>4</sup>I<sub>15/2</sub> (Er<sup>3+</sup>) → <sup>2</sup>F<sub>7/2</sub> (Yb<sup>3+</sup>) + <sup>4</sup>I<sub>11/2</sub> (Er<sup>3+</sup>)). After that, the Er<sup>3+</sup> ions at <sup>4</sup>F<sub>7/2</sub> state can be populated from the <sup>4</sup>I<sub>11/2</sub> state by the ET3 (<sup>2</sup>F<sub>5/2</sub> (Yb<sup>3+</sup>) + <sup>4</sup>I<sub>11/2</sub> (Er<sup>3+</sup>) → <sup>2</sup>F<sub>7/2</sub> (Yb<sup>3+</sup>) + <sup>4</sup>F<sub>7/2</sub> (Er<sup>3+</sup>)). The <sup>2</sup>H<sub>11/2</sub> and <sup>4</sup>S<sub>3/2</sub> states are populated from the <sup>4</sup>F<sub>7/2</sub> state owing to the NR relaxation, and then the Er<sup>3+</sup> ions at <sup>2</sup>H<sub>11/2</sub> and <sup>4</sup>S<sub>3/2</sub> states relax to the <sup>4</sup>I<sub>15/2</sub> state, leading to the green UC emissions (528 nm and 550 nm). The Er<sup>3+</sup> ions at <sup>4</sup>I<sub>11/2</sub> state can relax to the <sup>4</sup>I<sub>13/2</sub> state through the multiphonon relaxation (MPR) process, and then the Er<sup>3+</sup> ions at <sup>4</sup>I<sub>13/2</sub> state are excited to the <sup>4</sup>F<sub>9/2</sub> by ET2 (<sup>2</sup>F<sub>5/2</sub> (Yb<sup>3+</sup>) + <sup>4</sup>I<sub>13/2</sub> (Er<sup>3+</sup>) → <sup>2</sup>F<sub>7/2</sub> (Yb<sup>3+</sup>) + <sup>4</sup>F<sub>9/2</sub> (Er<sup>3+</sup>)). Meanwhile, the <sup>4</sup>F<sub>9/2</sub> state can be also populated from the <sup>4</sup>S<sub>3/2</sub> state through the NR relaxation. The Er<sup>3+</sup> at the <sup>4</sup>F<sub>9/2</sub> state will transit to the <sup>4</sup>I<sub>15/2</sub> state and thus emitted the red light (~654 nm).

### 3.3 Optical temperature-sensing properties

For investigating the optical temperature sensing characteristics of SrWO<sub>4</sub>:Ho<sup>3+</sup>/Yb<sup>3+</sup> phosphor, the emission spectra of the SrWO<sub>4</sub>:Ho<sup>3+</sup>/Yb<sup>3+</sup> sample are measured at different temperature. As shown in Fig. 5(a), it can be seen that the UC emission intensities of all emission band decrease with the temperature increasing. The possible reason is thermal quenching effect.<sup>23</sup> But the decreasing rate of the different emission band is different. Fig. 5(b) shows the UC emission intensity variation of 540 nm (<sup>5</sup>S<sub>2</sub>, <sup>5</sup>F<sub>4</sub> → <sup>5</sup>I<sub>8</sub>) and 756 nm (<sup>5</sup>S<sub>2</sub>, <sup>5</sup>F<sub>4</sub> → <sup>5</sup>I<sub>7</sub>) with temperature increasing. It is clearly observed that the UC emission intensity at 756 nm drops much more slowly than that at 540 nm with the temperature increasing. By considering the

Fig. 5 (a). Temperature-dependent on UC emission spectra of  $\text{SrWO}_4$ :1% $\text{Ho}^{3+}$ /2% $\text{Yb}^{3+}$  phosphor at 303–573 K. (b). The emission intensity of  $\text{SrWO}_4$ :1% $\text{Ho}^{3+}$ /2% $\text{Yb}^{3+}$  phosphor center at 540 nm and 756 nm change in the range 303–573 K. (c) Four-level simplified diagram of transitions from adjacent excited levels to two lower levels. (d) The FIR ( $I_{756 \text{ nm}}/I_{540 \text{ nm}}$ ), (e) the absolute sensitivity based on the  $I_{756 \text{ nm}}/I_{540 \text{ nm}}$ , (f) the relative sensitivity based on the  $I_{756 \text{ nm}}/I_{540 \text{ nm}}$ .

thermalization between  ${}^5\text{S}_2$  and  ${}^5\text{F}_4$  levels, the FIR of the UC emission from  $({}^5\text{F}_4, {}^5\text{S}_2) \rightarrow {}^5\text{I}_8$  and  $({}^5\text{F}_4, {}^5\text{S}_2) \rightarrow {}^5\text{I}_7$  transitions can be analyzed by using a four-level system, which was introduced by González-Pérez *et al.*<sup>24</sup> as shown in Fig. 5(c). The  ${}^5\text{S}_2$ ,  ${}^5\text{F}_4$ ,  ${}^5\text{I}_7$  and  ${}^5\text{I}_8$  levels form a four-level system. The emission intensity is proportional to the population of each energy level and the population of the excited state relates to the temperature. So the FIR can be expressed by the following eqn (2).<sup>25</sup>

$$\text{FIR}_1 = \frac{I_{756 \text{ nm}}}{I_{540 \text{ nm}}} = \frac{C_1 + C_2 \exp(-\Delta E/kT)}{C_3 + C_4 \exp(-\Delta E/kT)} \quad (2)$$

where  $C_1$ ,  $C_2$ ,  $C_3$  and  $C_4$  are constants about spontaneous emission rate, energy level degeneracy and emission energy.  $\Delta E$  is the energy gap of the  ${}^5\text{S}_2$  and  ${}^5\text{F}_4$ ,  $k$  is the Boltzmann constant, and  $T$  is the absolute temperature. It can be seen in Fig. 5(d), the FIR of the  $I_{756 \text{ nm}}/I_{540 \text{ nm}}$  regularly changes with the temperature increasing. It shows a nonlinear variation of FIR value at the temperature range 303 to 573 K. The eqn (2) is used to well fit the data, the  $C_1$ ,  $C_2$ ,  $C_3$ ,  $C_4$  and  $\Delta E$  are 0.15,  $-0.3$ , 2.98,  $-6.1$  and  $429.15 \text{ cm}^{-1}$ , respectively.

In the experiment, absolute sensitivity ( $S_a$ ) is a non-negligible evaluation index of temperature, which indicates the absolute change of FIR in unit temperature, as shown in eqn (3).

$$S_a = \left| \frac{d\text{FIR}}{dT} \right| \quad (3)$$

Relative sensitivity ( $S_r$ ) is also an important parameter that can be described as:

$$S_r = \left| \frac{1}{\text{FIR}} \frac{d\text{FIR}}{dT} \right| \quad (4)$$

$S_a$  and  $S_r$  of the sample are shown in Fig. 5(e) and (f), which are fitted by eqn (3) and (4). The  $S_a$  increases with the temperature enhancement, reaching a maximum of  $0.0017 \text{ K}^{-1}$  at 573 K. While the maximum value of  $S_r$  is  $1.27\% \text{ K}^{-1}$  at 573 K.

Fig. 6(a) shows that the emission intensities of the green and red band vary with temperature increasing. It can see that the intensity of red emission decreases more slowly than that of green emission. The energy levels  ${}^5\text{S}_2$ ,  ${}^5\text{F}_4$  and  ${}^5\text{F}_5$  energy levels are far apart, and the particle population at the two energy levels do not follow the Boltzmann-type distribution. The  ${}^5\text{S}_2$ ,  ${}^5\text{F}_4$  and  ${}^5\text{F}_5$  belong to non-TCLs. So the traditional FIR analysis method based on TCLs is not appropriate for the non-TCLs system. In the previous report, the relation of the non-TCLs FIR and temperature can be fitted by eqn (5).<sup>26</sup>

$$\text{FIR}_2 = \frac{I_{540 \text{ nm}}}{I_{663 \text{ nm}}} = a + bT + cT^2 \quad (5)$$

Fig. 6(b) shows that the original data for the  $I_{540 \text{ nm}}/I_{663 \text{ nm}}$  as a function of the temperature fitting with the eqn (5). Consequently the FIR based on  ${}^5\text{S}_2$ ,  ${}^5\text{F}_4/{}^5\text{F}_5$  ( $\text{Ho}^{3+}$ ) shows the significant temperature dependence and well fits the eqn (5). The curve of  $S_a$  and  $S_r$  by calculation and fitting are shown in Fig. 6(c) and (d). The  $S_a$  goes down with the increasing of temperature. The maximum  $S_a$  is  $0.0158 \text{ K}^{-1}$  at 303 K. While the  $S_r$  reaches a maximum of  $0.41\% \text{ K}^{-1}$  at 393 K. The above analysis of the sensitivity of  $\text{SrWO}_4$ : $\text{Ho}^{3+}$ /

Fig. 6 (a) The emission intensity of  $\text{SrWO}_4:1\%\text{Ho}^{3+}/2\%\text{Yb}^{3+}$  phosphor center at red (663 nm) and green (540 nm) changes with temperature. (b) The FIR ( $I_{540\text{ nm}}/I_{663\text{ nm}}$ ), (c) the absolute sensitivity and (d) the relative sensitivity of  $\text{SrWO}_4:\text{Ho}^{3+}/\text{Yb}^{3+}$  phosphor as a function of temperature.

$\text{Yb}^{3+}$  based on the TCLs and the non-TCLs shows that the sample has high sensitivity and it has certain application value in optical temperature measurement.

Besides, the  $\text{Er}^{3+}-\text{Yb}^{3+}$  co-doped  $\text{SrWO}_4$  phosphor has also been studied for its sensing properties. As shown in Fig. 7(a),

the UC emission spectra of green light in the different temperature are recorded. The UC luminescence intensities of 528 nm and 550 nm (generated by  $^2\text{H}_{11/2} \rightarrow ^4\text{I}_{15/2}$  and  $^4\text{S}_{3/2} \rightarrow ^4\text{I}_{15/2}$ ) vary differently with the change of temperature. At 313 K, the intensity of the two emission bands is almost equal, with the

Fig. 7 (a) Temperature-dependent green UC emission spectra of  $1\%\text{Er}^{3+}/1\%\text{Yb}^{3+}$  co-doped  $\text{SrWO}_4$  phosphor at 313–573 K. (b) dependence of FIR for  $I_{528\text{ nm}}/I_{550\text{ nm}}$  on absolute temperature. (c and d) The variation of absolute sensitivity and the relative sensitivity for  $\text{SrWO}_4:1\%\text{Er}^{3+}/1\%\text{Yb}^{3+}$  phosphor with temperature between 313 K and 573 K.

Fig. 8 (a)  $\Delta\text{FIR}$  and (b)  $\Delta T$  of  $\text{SrWO}_4:\text{Ho}^{3+}/\text{Yb}^{3+}$  based on the non-TCLs ( $^5\text{S}_2$ ,  $^5\text{F}_4/{}^5\text{F}_5$ ) and  $\text{SrWO}_4:\text{Er}^{3+}/\text{Yb}^{3+}$  based on the TCLs ( $^2\text{H}_{11/2}/{}^4\text{S}_{3/2}$ ) pair at 303–573 K.

temperature increasing, the luminescence intensity of the 528 nm emission band is gradually increased within 313–433 K, and that of the 550 nm emission band gradually decreases. Then, in the range of 433–573 K, as the temperature increasing, the intensities of two bands also decrease because of the non-radiative relaxation enhancement. But the luminescence intensity of the 550 nm emission band decreases faster than that of 528 nm emission band. When the temperature increases, the electrons at  ${}^4\text{S}_{3/2}$  state are excited. The transition from  ${}^4\text{S}_{3/2}$  to  ${}^2\text{H}_{11/2}$  occurs. It indicates that the  ${}^2\text{H}_{11/2}$  and  ${}^4\text{S}_{3/2}$  states of  $\text{Er}^{3+}$  can be regarded as TCLs, and the electrons population at  ${}^2\text{H}_{11/2}$  and the  ${}^4\text{S}_{3/2}$  states follows the Boltzmann distribution. The FIR of TCLs can be expressed by the eqn (6):<sup>27</sup>

$$\text{FIR} = \frac{I_{528 \text{ nm}}}{I_{550 \text{ nm}}} = C \exp\left(-\frac{\Delta E}{kT}\right) \quad (6)$$

The changing of FIR of  $I_{528 \text{ nm}}/I_{550 \text{ nm}}$  with temperature is displayed in Fig. 7(b), which is fitted by eqn (6). According to the fitting curve of the experimental data, the calculated C value is 24.29 and  $\Delta E/k$  is 1012.9, so the  $\Delta E$  between  ${}^2\text{H}_{11/2}$  and  ${}^4\text{S}_{3/2}$  is  $703.7 \text{ cm}^{-1}$ , which is very close to the experiment value of  $758 \text{ cm}^{-1}$ , the latter is obtained from the UC emission spectrum. Fig. 7(c) shows the  $S_a$  of  $\text{SrWO}_4:1\%\text{Er}^{3+}/1\%\text{Yb}^{3+}$

phosphor. The  $S_a$  of the phosphor increases at first and then decreases, reaching a maximum of  $0.013 \text{ K}^{-1}$  at 513 K. In Fig. 7(d) the  $S_r$  also is calculated, and the  $S_r$  reaches a maximum of  $1.03\% \text{ K}^{-1}$  at 313 K.

In addition, thermal resolution ( $\Delta T$ ) is also a key parameter, which can be defined as:

$$\Delta T = \frac{\Delta\text{FIR}}{\text{FIR}} \frac{1}{S_r} = \frac{\Delta\text{FIR}}{S_a} \quad (7)$$

where  $\Delta\text{FIR}$  is the uncertainty of FIR,  $S_r$  is the relative sensitivity, and  $S_a$  is the absolute sensitivity. The  $\Delta\text{FIR}$  can be calculated by the following equation.

$$\Delta\text{FIR} = \frac{\sum_{i=1}^{i=n} |\text{FIR}_i - \overline{\text{FIR}}|}{n} \quad (8)$$

where  $\overline{\text{FIR}}$  and the corresponding uncertainty  $\Delta\text{FIR}$  are the average and the standard deviation values from 20 measurements at each temperature,  $\text{FIR}_i$  is the  $i$ -th FIR measured at the same temperature and  $n$  is the number of measurements.

For  $\text{SrWO}_4:\text{Ho}^{3+}/\text{Yb}^{3+}$  phosphor, the thermal resolution of temperature measurement based on the non-TCLs ( $^5\text{S}_2$ ,  $^5\text{F}_4/{}^5\text{F}_5$ ) FIR has been investigated. While the thermal resolution of temperature measurement based on the TCLs ( ${}^2\text{H}_{11/2}/{}^4\text{S}_{3/2}$ ) also has been discussed for  $\text{SrWO}_4:\text{Er}^{3+}/\text{Yb}^{3+}$  phosphor. The values

Table 1 Comparison of the maximum sensitivity of  $\text{Ho}^{3+}(\text{Er}^{3+})/\text{Yb}^{3+}$  doped in different material

Materials	Energy level	$S_r (\text{K}^{-1})$	$S_a (\text{K}^{-1})$	Reference

$\text{SrWO}_4:\text{Ho}^{3+}/\text{Yb}^{3+}$	${}^5\text{S}_2, {}^5\text{F}_4/{}^5\text{F}_5$	0.41% (393 K)	0.0158 (303 K)	This work

of  $\Delta\text{FIR}$  and  $\Delta T$  are presented among the range of 303–573 K in Fig. 8(a) and (b), respectively. It can be seen that the  $\Delta\text{FIR}$  of  $\text{SrWO}_4:\text{Ho}^{3+}/\text{Yb}^{3+}$  is lower than that of  $\text{SrWO}_4:\text{Er}^{3+}/\text{Yb}^{3+}$ . At 303 K, the  $\Delta T$  of  $\text{SrWO}_4:\text{Ho}^{3+}/\text{Yb}^{3+}$  and  $\text{SrWO}_4:\text{Er}^{3+}/\text{Yb}^{3+}$  have the minimum values of 0.72 K and 1.14 K, respectively. The values of  $\Delta T$  become increasingly with the temperature enhancement. Therefore, the samples have better accuracy at lower temperature.

In order to correctly evaluate experimental results, the other materials doped with different RE ions are compared in Table 1. It can clearly conclude that the sensitivity of our sample is higher than that of the most of samples in the table.

## 4. Conclusion

In conclusion, the  $\text{SrWO}_4:\text{Ho}^{3+}(\text{Er}^{3+})/\text{Yb}^{3+}$  phosphors are successfully prepared by solid state reaction method. The UC luminescence properties of  $\text{SrWO}_4:\text{Ho}^{3+}(\text{Er}^{3+})/\text{Yb}^{3+}$  samples are investigated under 980 nm excitation. Furthermore, the temperature sensing properties of the  $\text{Ho}^{3+}:\text{S}_2/\text{F}_4$  (TCLs),  $\text{Er}^{3+}:\text{H}_{11/2}/\text{S}_{3/2}$  (TCLs) and the  $\text{Ho}^{3+}:\text{S}_2, \text{F}_4/\text{F}_5$  (non-TCLs) are investigated in the temperature range of 303–573 K. Specifically, the absolute sensitivity value reaches  $0.0158 \text{ K}^{-1}$  at 303 K for  $\text{Ho}^{3+}:\text{S}_2, \text{F}_4/\text{F}_5$  (non-TCLs) and the relative sensitivity value reaches 0.41% at 393 K, which is superior to most optical temperature sensing materials doped with  $\text{RE}^{3+}$  ions. It means that the  $\text{SrWO}_4:\text{Ho}^{3+}/\text{Yb}^{3+}$  can achieve higher absolute sensitivity by FIR of non-TCLs, as well as it has potential application in optical temperature sensors.
